PREFACE

Manfred SCHRENK,
Chairman CORP, Managing Director of CEIT – Central European Institute of Technology &
CEIT ALANOVA - Institute of Urbanism, Transport, Environment and the Information Society, Schwechat, Austria

A very warm WELCOME to VIENNA/AUSTRIA,
and to
REAL CORP 2010,
the
15th International Conference on Urban Planning & Regional Development in Information & Knowledge Age

under the general topic of
CITIES for EVERYONE:
Liveable, Healthy, Prosperous!

Of course this topic is meant as an urgent appeal, but in the second line there is already the question:

PROMISING VISION or UNREALISTIC FANTASY?

Can cities ever be liveable, healthy and prosperous for everyone?

Cities are and have always been places of competition, stress, inequalities, traffic jams, environmental stresses and strains and permanent struggle. Cities often are an aggressive environment, not only for children, the elderly and the weak.

On the other hand cities are the centres of economy, culture, creativity, science and innovation and therefore provide excellent perspectives and a lot of chances for many people – cities are attractive places! Meanwhile more than 50 percent of world population lives in cities, soon it will be about 70 percent.

REAL CORP 2010 asks for cities for everyone that are liveable, healthy and prosperous. Is this a promising vision we should work on or is it an unrealistic fantasy? Is it possible to keep and even improve the advantages of cities and reduce the negative effects? Or does the one aspect require the other? What are the possibilities and contributions of urban planning and real estate development? How can ICT, urban, transport and environmental technologies help to improve quality of our life in cities?

To pick out just one topic that is hardly asked until now in the public discussion (at least in Europe): Do we really always have to try to adopt cities and neighbourhoods to the needs of the people currently living there?
Or is it possible to make "offers" for certain groups of people to find the best surrounding for their lifestyles for a limited time and therefore move in and out to certain areas according to their phase of life?
Does the second way automatically lead to monotonous ghettos with uniform inhabitants? Or is there a way to keep up the mixture and variety that is one of the key aspects of urban life?

REAL CORP 2010 covers many different topics in more than 150 presentations. The proceedings comprise more then 1350 pages of hand-picked knowledge for planners and for cities.

It is on purpose that CORP-topics are rather vaguely defined and usually more questions are raised then actually answered.
Maybe this is against the trend as specialisation in science and research still wears on.

Cities are the most complex invention of mankind and the question of "The Future of Cities" can not be answered from just one perspective – so CORP tries to bring together experts from different fields and from all over the world and provides the stage for meeting and learn from each other.
A conference should never be only about papers and presentations – it's the face-to-face contacts that generate new thoughts and friendships!

Have a great conference!

1 ABSTRACT

A sustainable and sustaining planning strategy is globally important for metropolitan areas. Sustainable planning addresses the development of strategies to reduce the use of resources, increase economic efficiency and improve integration of social aspects (e.g. pedestrian friendly environments, well balanced public and private transport modes, efficient street networks; land use, movement economy; access for all to jobs, retail, services, healthcare, culture, and leisure). In order to reduce urban sprawl, numerous authors recommend going back to the concept of compact cities. However, policies favoring the compact city concept turned out to be less efficient than expected. Indeed, a large number of households choosing these areas reject urban density since they prefer living in individual houses surrounded by a garden and enjoy a green and calm environment.

Hence, instead of rejecting urban sprawl it seems more reasonable to find solutions for better managing the dynamic aspects of cities, in order to reduce traffic costs and pollution, and to avoid undermining natural and agricultural resources. Frankhauser (2004) first proposed reflections onto what extent planning concepts referring to fractal geometry could be of interest for reducing negative impacts of urban sprawl. In a recent research project, financed by the French Ministry of Ecology, Energy, Sustainable Development and Sea in the framework of the PREDIT research program, a planning concept was developed concretizing this basic idea. A planning support system was developed which allows testing the efficiency of the concept (Frankhauser et al 2007, 2008).

Let us recall that fractal geometry is based on a hierarchical principle, which has been to be an essential element of urban structures. The hierarchical ordering principle is a cascade of similar elements on different levels of detail: house, block, quarter, district - or: path, residential road, side street, main road, freeway, and highway. According to Read (Read 2000), different scales of hierarchy are distinguished by scales of mobility, and are designed to convey different scales of movement. The spatio-functional pattern describes everyday space use and movement. The above-mentioned fundamental systematic of the built environment requires a structural-analytical approach on all interwoven scales (global to local) for future developments (regional, urban and architectural). The multi-scale logic allows the articulation of residential areas and leisure areas across scales, introducing different levels of service centres according to their frequency of use. These service centres are localized in the nodes of the transportation system thus improving their accessibility with respect to residential areas.

This paper addresses a further development of this theoretical model, extending it to be a holistic, comprehensive system. The idea of an “urban” hierarchy (street network, green areas, building blocks, building heights, and urban centres), generated as a multi-scale urban planning model for developing scenarios (regional, urban, architectural scale - 2D & 3D) for metropolitan areas, allows the implementation of highly efficient, functional and sustainable transport networks, masterplans and mass models.

The comprehensive system presented here can not only simulate growth scenarios but also assesses the quality of an existing area for consolidation and revitalisation (masterplan, urban fringe) or to identify areas with low overall access for a sustainable negative growth scenario (inverse model for shrinking cities and quarters).

2 INTRODUCTION

The basic principles of the built environment are the relationships between physical elements and between physical elements and dynamic components. These can be described as “spatial packing” (Franck 2005). They aggregate on different scales through interactions of dense and separated spaces created by

fluctuations. Hence, two major architectural definitions emerge as the basis of cities' spatial nature: buildings and movement channels.

The constitution of space (e.g. the aspect of accessibility and centrality) is determined by its spatial organisation. The term organisation refers to Hillier's terminology *spatial configuration* (Hillier 1996) - a set of relationships. Configuration can be analysed and understood on all scales - from regional planning to urban planning and design, and further to architecture itself. The geometric pattern of spatial configuration of dense and separated spaces is accomplished by a system of piling and accessibility. Every space connects other spaces as well as itself. This scheme repeats itself on all scales to such an extend that we can speak of it as a fractal structure (fragmented, self-similar, multi-scale). Research has shown that a hierarchically structured ordering principle of urban agglomeration are self-organising and exists everywhere where people have to share limited amount of space. Self-organisation structures the space in traditional European towns as well as in synthetically ones (Batty and Longley 1994, Frankhauser 1994, Frankhauser 2008, Franck 2005).

The characteristic of a city (fractal structure) demands a structure-analytical approach on all interacting scales (regional scale, urban scale, and architectural scale). The idea of hierarchy as a foundation for developing an urban growth model allows an efficient usage of space by using the law of all living systems. The combination of configuration and accessibility (individual transport, public transport) combined with plot sizes, free spaces, building volumes and building heights (population density) puts the built environment in the context of ecological and socio-economic aspects. Regional and urban models which take these factors in consideration represent a holistic strategy for sustainable and sustaining planning. Visionary scenarios demand an interdisciplinary approach from architecture, regional planning and geography. In the course of urban and regional development in Europe over the last decade, sustainable strategies have become the focal point of planning strategies on all scales.

2.1 Sustainable and Sustaining Development

The Brundtland Report of the United Nations defines sustainability as "[…] development that meets the needs of the present without comprising the ability of future generations to meet their own needs". The report also comments on the availability of non- renewable resources "as their use reduces the stock availability for future generations. […] But this does not mean that such resources should not be used. In general, the rate of depletion should take into account the criticality of the resource, the availability of technologies for minimizing depletion, and the likelihood of substitutes being available." (Brundtland Report, Our Common Future, Chapter II, 1987).

Transport and network strategies play a key role in this context as high accessibility (pedestrians, public and individual transport) is a major aspect in reducing the use of resources (fossil fuels) and at the same time minimizing a community's carbon foot print of which, in the developed world, 13% is contributed by transport an 7% by car manufacture. The figure below shows the main elements which make up the total of a person's carbon footprint in the developed world.

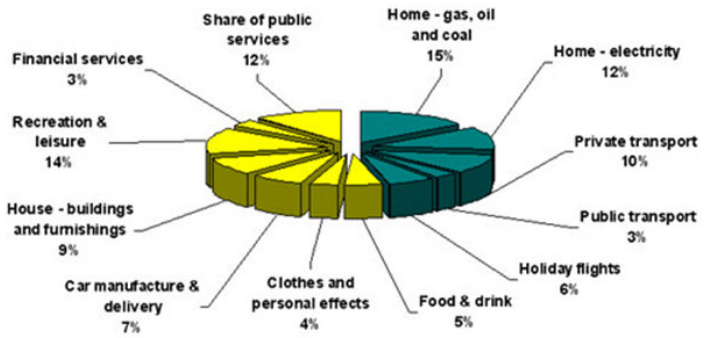

Fig. 1: A carbon footprint is made up of the primary foot print (blue slices) and the secondary foot print (yellow slices). The primary footprint is a measure of direct emissions of CO2 from the burning of fossils (a person is in direct control of these). The secondary foot print is a measure of indirect emissions of CO2 from the whole life circle of products (www.uhv.edu, accessed 2010).

Highly efficient transport and network strategies support users when using the car to produce less carbon dioxide, and give the opportunity to use public transport on more occasions or simply walk or ride the

bicycle to the aimed location. Therefore, sustainable planning strategies not only influence the usage pattern (primary carbon foot print), but also reduce production and consumption (secondary carbon foot print), and the depletion of no-renewable resources.

To make a built environment work sustainable we also need to take into account the aspect of density. This complex dynamic between density and transport infrastructure must not be a reactive process. The choice of transport mode influences land use, this, in turn, influences the transport mode (individual transport, public transport, pedestrian). In general, sustainable transport strategies can only function on the basis of an efficient network with high accessibility, connectivity, centrality and potential through movement (preferred for pedestrians within an urban system). Further, on different scales the whole network needs to be distinguished into a pedestrian network, bicycle network, private vehicle network, bus and rail network, freight network, transit network, and green network. For all these networks the same rules apply as to the system as a whole.

The reduction of consumption of resources does not only take into consideration the three areas of sustainable development - ecology, economy and social aspects - but also allows cities and regions to act independently from international and political decisions.

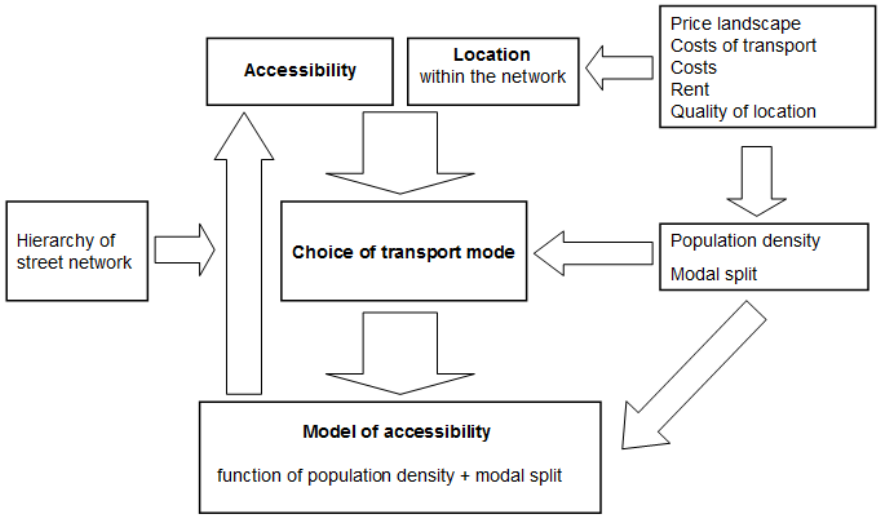

Fig. 3: Interdependency of accessibility and socio-economic factors (Czerkauer 2009)

Let us recall that since the critique of Newman and Kenworthy (1989), many authors have seen in the compact city, a solution for reducing individual transport (Dantzig et Saaty 1973). Experience shows however, that policies favoring the compact city turn out to be less efficient than expected, not least, because the affected population has a critical view of a high-density approach (Garcia et Riera 2003, Remy 1994). In reality, surveys made evident that a moderate to high percentage of people prefer households close to green areas, low density developments and quiet living areas which are important factors in location choice (eg. Guénaëlle Gault / Laurence Bedeau 2007). Hence it seems difficult to convince such households to come back to density (e.g. Owens 1992, Breheny 1997, Garcia et Riera 2003). Schwanen et al. (2004) argue that households tend to minimize the distance or the travel time not only with respect to work, as also shown by Brun and Fagnani (1994) and McDowell (1997), but they optimize their residential location with respect to different kinds of spatial amenities that they frequent as well. This holds, e.g., for commercial areas (Lerman 1976) or even leisure areas (Guo and Bhat 2002). It reinforces the risk that households relocate to a lower-density environment, which risks increasing the costs of housing, traffic congestion and reduces the accessibility of leisure areas (Breheny 1997).

3 MULTI-SCALE PLANNING MODEL

3.1 Theory and Methodology

3.1.1 The Basic Ideas

As pointed out, simple models referring to monocentrism and densification of residential areas seem not to be realistic alternatives for managing urban sprawl. The concept presented by this paper refers to a

hierarchical organization of metropolitan areas. The hierarchical structure of an agglomeration, developed based on social and economic interaction and interdependency between the locations (e.g. villages), has been investigated in urban geography for a long time. These observations served Christaller as foundation for his Central Place Theory (Christaller 1933). He was able to explain the hierarchy of centres, namely, that the catchment areas of different services are dependent on how often the services are used. That is why the services for everyday life (e.g. supermarket) are close to housing, whereas weekly or monthly services require bigger catchment areas. By this characteristic services can be distinguished, leading to a centre-hierarchy (global centre, intermediate centre, local centre) with diverse catchment areas (Figure 3). However, Christaller's theory is constrained to only concerning a functional hierarchy, not reflecting the spatial structure. This explains why in Christaller's theory locations are evenly distributed across the spatial surface plane. The accessibility of such a distribution is disadvantageous for several reasons. On one hand it demands a pseudo-homogeneous traffic infrastructure, on the other hand all of the remaining free spaces are approximately the same size.

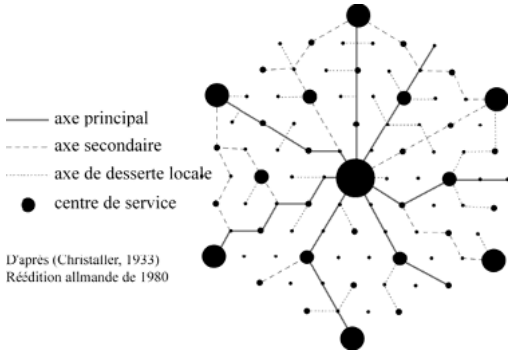

Figure 4: Christaller's net of central places including traffic infrastructure (Christaller 1933, reprint 1980)

In the framework of the PREDIT research program, financed by the French Ministry of Ecology, Energy, Sustainable Development and Sea, a planning concept was developed at the ThéMA institute (Université de Franche-Comté) featuring Christaller's centre-hierarchy, in which spatial distributions are linked to the hierarchy of the traffic infrastructure, equating to a multi-fractal structure (Frankhauser et al. 2007, 2008).

In doing so, the agglomerations are pushed closer to the main traffic axes, decreasing distances and increasing accessibility from and to services. The structured services in Christaller's centre-hierarchy are localised in traffic nodes and have different sized catchment areas. The designed traffic system, using a radio-concentric principle, offers high accessibility with regard to its functional impact (global centre, intermediate centre, local centre). This axes-oriented concept concentrates and lumps traffic flows and therefore allows public transport to be prioritised. In addition, a hierarchically organised system of linked free spaces allows small green areas to be obtained next to housing estates as well as nature resorts and vast woodlands. Therefore, the green corridor principle is expanded as not only non-built-up surfaces and corridors are kept free, but also the interweavement of urban space and free space on all scales becomes the leading concept. On purpose, the urban edge and agglomeration fringes are not chamfered, but linked to green spaces on all scales in order to reduce traffic flow and minimize travel distance to leisure areas.

The linked spatial system of free spaces and agglomeration avoids uncontrolled and splinter developments. Ergo, this concept addresses all postulations of sustainability without propagandising a mono-centric, compact city model.

The concept presented allows the integration of the above described needs reducing environmental pollution at the same time. In summary, the model is a further development of Ebenezer Howard's garden city in combination with Christaller's Central Place Theory. Green areas are prioritised (grey wedges - figure far right).

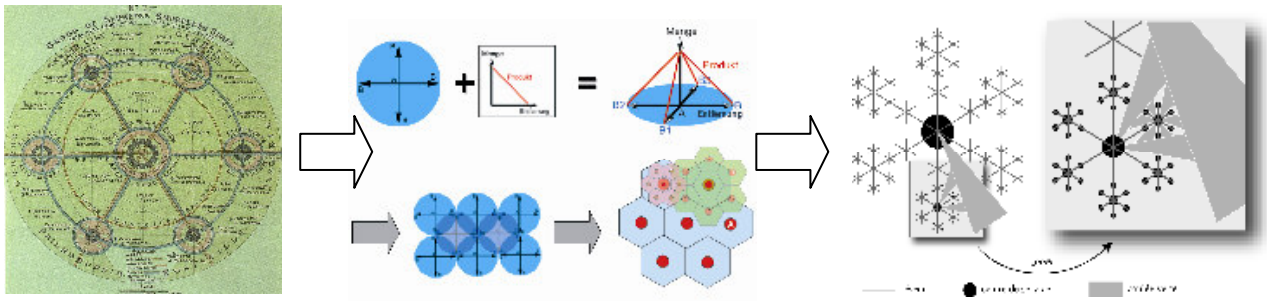

Fig. 5: Theoretical model derivation – far left: Ebenezer Howard's garden city (Wikipedia 2009), middle: Christaller's model (Czerkauer 2007), far right: Frankhauser's fractal model (Frankhauser et al 2007)

An important feature of the concept consists of distinguishing different levels of services according to their frequency of use. For the reduction of pollution, it seems crucial to localize services for daily needs next to residential areas. Services or malls frequented once a week can be placed at a greater distance. Hence, according to frequency of use, the concept distinguishes at least three levels of services and commerce. The goal is to develop planning scenarios respecting the multiscale logic of the concept. For this aim, a given situation is first analysed. Then, predefined standards are applied for developing planning scenarios. The standards refer to the following topics:

- the multi-scale soil occupation index, which corresponds to fractal dimension measures;
- morphological aspects like the articulation of built-up space and open landscape across scales;
- the accessibility of urban amenities (retail centers, services) and green amenities (leisure areas);
- the potential of city-size development (rank-size distribution of cities);
- natural and environmental constraints or recommendations.

These rules are implemented in a planning support system allowing the conception of scenarios for future development in an interactive way starting from a cartographic representation of the considered area.

In the framework of the French research project, a particular method, fractal decomposition, and a software package (MUP-city) has been developed which intergrates fractal, morphological and accessibility rules for services (Frankhauser et al 2007, 2008; Tannier et al 2010). This tool is particularly adapted for working on an urban scale (see below). In the framework of the project Fractalopolis, it is intended that an application concept that allows us to go even further will be developed, taking into account the regional level and including the 3rd dimension, i.e. the height of buildings.

3.1.2 Regional Model

Before applying the regional model, a region's qualitative and quantitative generic (growth) potential is identified by geometry, demographic data sets and morphology. From the present situation of a region, a variety of geometric and demographic analyses (agglomeration sizes, agglomeration hierarchies, cluster, population, distances and many others) are carried out to generate the model's scaling factors (reduction factors for a multi-fractal approach) for the best fit (structure-function model).

Based on an algorithm (including buffers for non-potential zones such as water areas, natural parks, etc.) the model will then be adjusted to the existing network and agglomerations. The simulated scenarios undergo an assessment (accessibility, services, etc.) to identify the advantages and disadvantages of each scenario.

In particular, the interface between existing urban morphology and new potential development (from the simulation) is an interesting challenge, as we have to deal with a non-linear urban fringe, with underlying characteristics of self-organisation paired with former planning and building interventions. The strategy of merging simulated and existing networks is of major importance as the urban development and extension has to be continuous, without any noticeable phase transition, neither for the urban structure nor for the residents of the area. Standards have to be developed corresponding to a city's population, ranking different levels of central places.

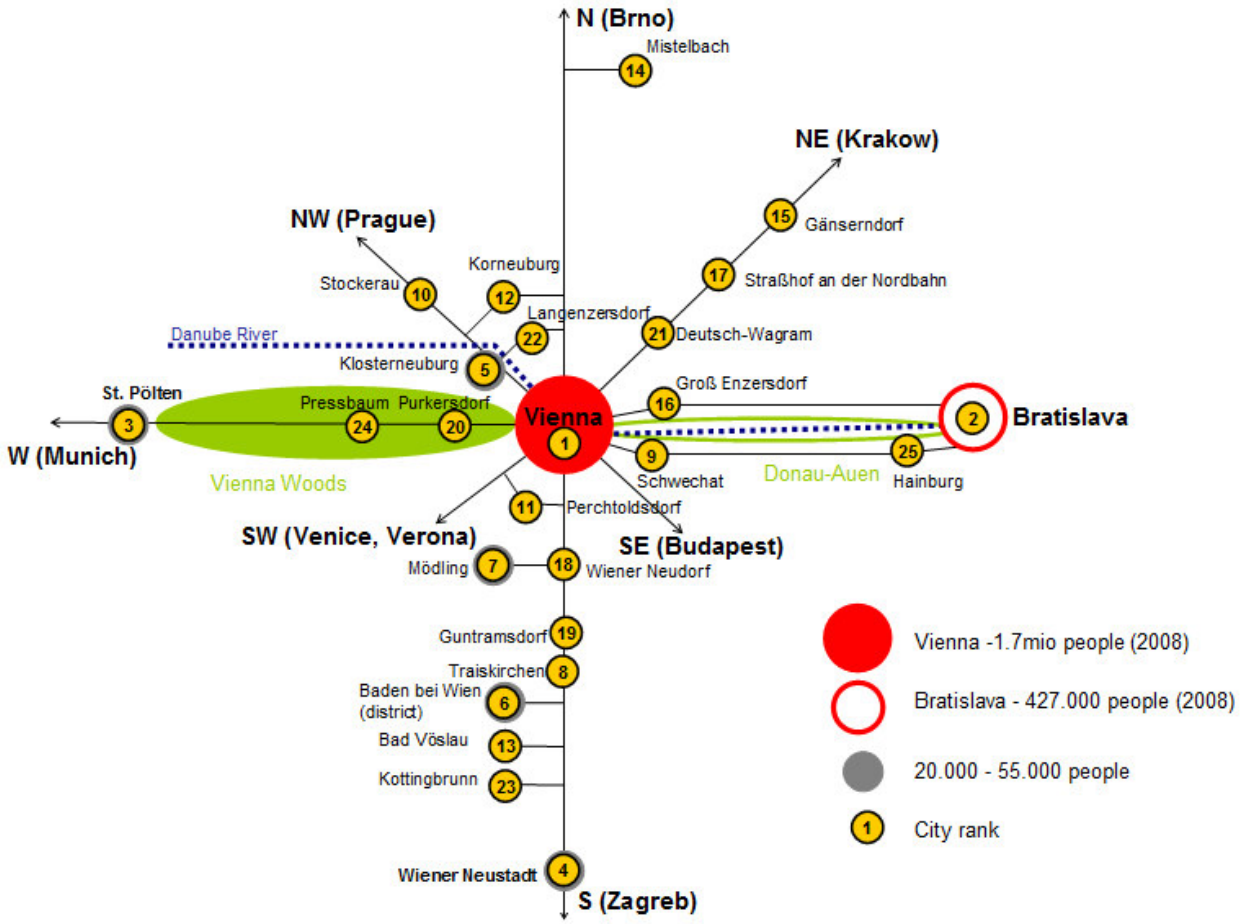

Figure 6: Schemata - City ranking by population of the Vienna-Bratislava metropolitan region (Czerkauer 2010)

In the framework of the fractalopolis-project, it is intended that a decision support system will be developed, which allows the evaluation of development scenarios on the regional scale. With this tool, rules and standards will be implemented referring to the situation on the regional scale. However, we must be aware that on this scale the logic will be different from that of the urban scale, since the pre-existing settlement network comes into play. Indeed, it is easier to develop sites (or not) within a city than to build new cities or urban districts.

3.1.3 Urban Model

In order to apply the planning concept on an urban scale the method of "fractal decomposition" was developed, which is similar to that of grid analysis currently used in fractal analysis (Mandelbrot 1983). The area under consideration is covered by a grid of square-like cells, their size being large in the first step (e.g. 540 m). We identify the "occupied" cells, i.e. those containing buildings. In the next step, each of these cells is cut into nine smaller squares, i.e. the size of the squares is a third of the initial one (fig. 7). In each of the occupied cells identified, we look again for those containing buildings. Of course, since our cells are smaller, we will again find empty ones within the occupied larger cells of the previous step. Hence the total ratio of occupied cells decreases from one step to the other, which corresponds to a decrease in intensity. This procedure is reiterated up to the size of the cells corresponding approximately to that of plots (e.g. 20 m). One of the decomposition steps for a real world pattern is illustrated in figure 8.

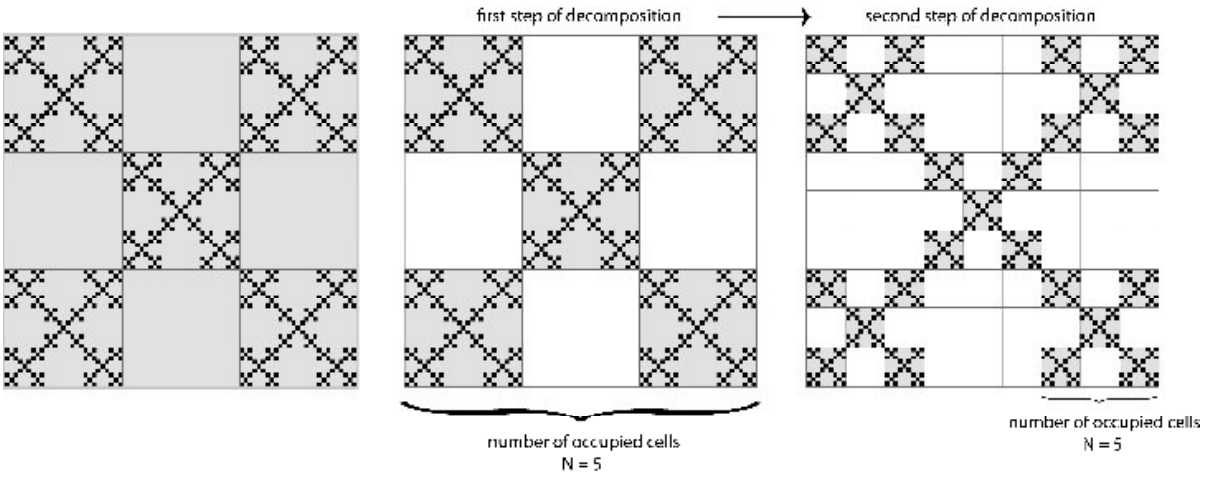

Figure 7: Fractal planning scheme (Frankhauser et al 2008)

In order to avoid fragmentation for urbanized areas as well as for open landscape, the concept demands topological rules of interconnectedness of free space and built up surfaces and a multi-scale hierarchical configuration.

On an urban scale, accessibility to jobs, services, leisure, etc. is of major importance. For a sustainable settlement, service clusters and facilities have to function on different levels (daily, weekly, monthly) indicating a certain catchment area (150-250m, 400-600m, 2-6km, 4-10km radius) linked to a catchment population. Hence, MUP-city evaluates the overall accessibility of each cell with regard to the existing network as well as accessibility to diverse services (Tannier et al 2010). Based on these criteria, MUP-city provides, at each decomposition step, global information for each cell about its suitability for future development. This is shown for one decomposition step in figure 8. By selecting a specific selected cell (surrounded in blue) detailed information are shown in the box. We must be aware that the number of cells which can be urbanized is constrained by fractal law. With this in mind, the larger meshes surrounded by a dark yellow line are introduced. Each of these larger meshes contains nine small meshes but, according to the chosen fractal law only Nmax of these cells can be urbanized. This holds for all meshes and for all decomposition steps.

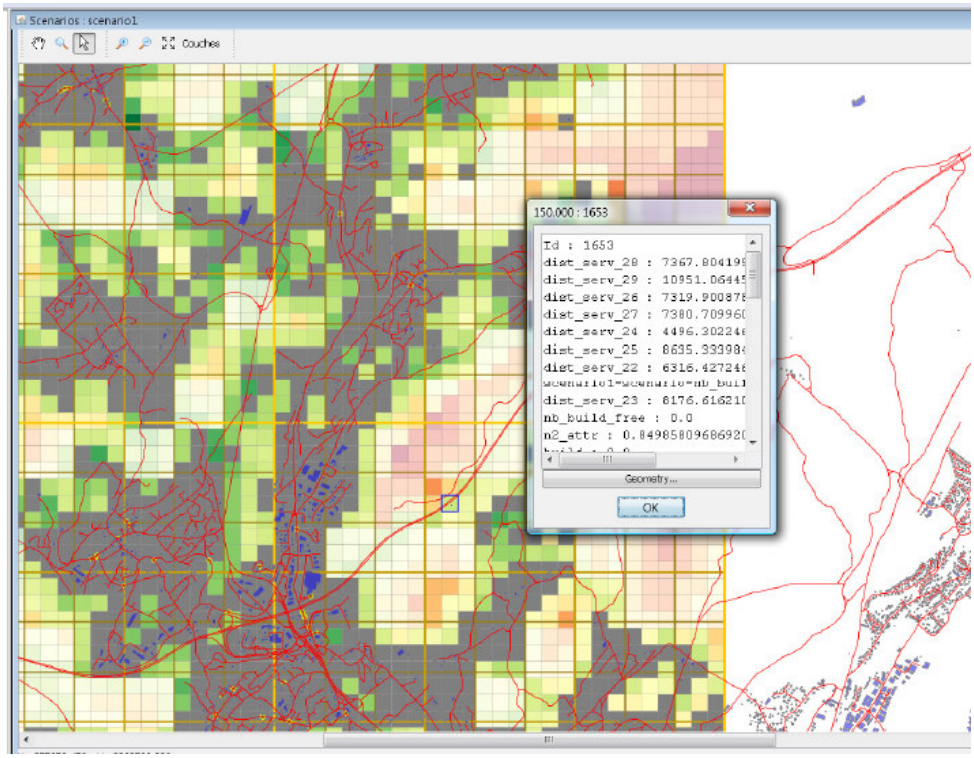

Figure 8: Example MUP-city: Evaluating a scenario based on the accessibility to services

This model not only simulates growth potential, but can also be used as an inverse model to identify areas with low accessibility for consolidation, revitalisation and demolition (e.g. shrinking cities and quarters).

In the present research context a more generalized approach has been developed. Instead of using a unique size of elements at each scale - the square-like meshes of a grid - we introduce the possibility to combine different sizes of squares, according to a multi-fractal logic. This multi-fractal decomposition allows the development of a more architectural approach, taking into account the different sizes of buildings. From a fractal point of view, it is then possible to have a kind of gradient from the centre to the periphery, where larger buildings tend to be localized in the centre. However, fractality allows buildings of different size to be combined in the different zones, thus avoiding monotony. Figure 9 illustrates this possibility, which shows, moreover, how in a multi-fractal approach, built-up areas and free spaces may be combined with regard to the different hierarchy level (centre, sub-centre). From this strategic multi-fractal decomposition, a masterplan is generated. The planning support system will take into account such tools.

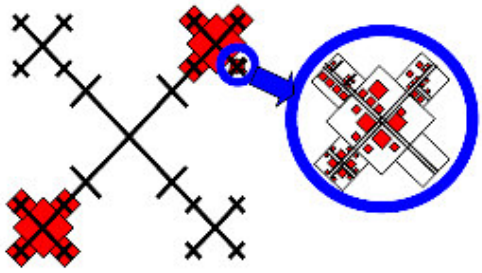

Figure 9: Strategic multi-fractal urban planning scheme (Frankhauser et al. 2005)

3.1.4 Architectural Model

Intensity of land use can be established by a) the morphology of built-up areas and b) a building height scheme (mass model). Intensity of land use regulates a plot's/block's/quarter's/agglomeration's population rank within a system (local to global, neighbourhood to region) and therefore has an impact on important economic and social forces.

A multi-fractal approach allows us not only to modify the size of buildings but also to take into account the intensity of land use, i.e. introducing the height of buildings. Hence, we can expect to develop a highly efficient distribution of built-up mass throughout the urban system, which can then link to a well balanced application of economic theories such as industrial location theories and their impacts on the built environment (centrality, accessibility, rent, landscape prise, capital, and costs). Figure 10 illustrates by means of a rather simple multi-fractal model how the intensity of land use can be modelled with a multi-fractal concept. We may imagine that the bars correspond to the spatial distribution of land use intensity along a street axis going from the city centre to the periphery. Figure 11 shows how different land use intensity factors (p1, p2 etc.) may be applied to different meshes of a grid for which we have chosen, for simplicity, the same size of meshes. These factors correspond to different heights. In further steps of decomposition, these factors are combined and hence a great diversity of intensity factors occur, respecting, however, the hierarchical logic which appears in figure 10 where only two intensity factors are combined.

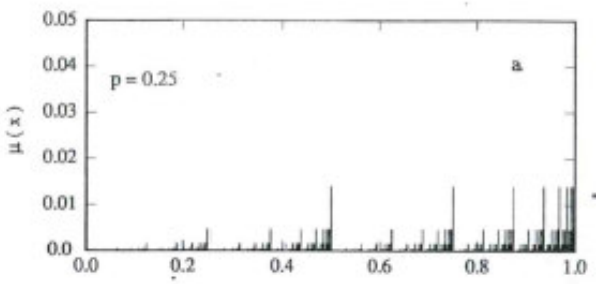

Figure10: A binominal multiplicative process is used for global height development (Feder 1988)

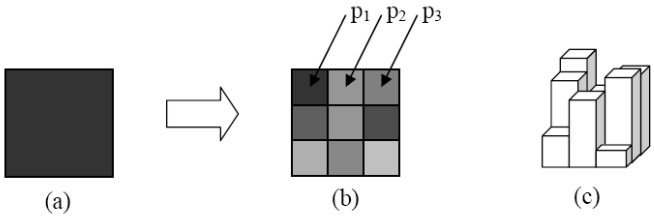

Figure 11: Schematic local height development based on a fractal operation (Frankhauser 2009)

The masterplan serves as the basis for an architectural mass model (3D). Based on its indicators (accessibility, centre hierarchy, closeness to services), each plot (of a cell) is multiplied by a certain height-factor retrieved from the present situation as well as demographic forecasts of the area under scrutiny. The planning support system will take into account this enlarged concept.

4 CONCLUSION

The multi-scale expert system supports regional planners, town planners and architects in developing sustainable scenarios (2D & 3D) for potential developments.

In addition, the multi-scale approach is used to control the intensity and density of land use and therefore economic forces. The new invention of this expert system is not only to use a multi-fractal approach for 3D modelling, but also to create stable and therefore sustainable and sustaining scenarios. This is only possible by addressing consistency through all scales based on functional geometric aspects:

- regional scale: agglomeration classification, street network including green and water areas, topography (2D)
- urban scale: masterplanning (2D + 3D)
- architectural scale: mass model (3D)

Only with an understanding of the interrelation of all interwoven scales on different zoom levels can thriving and sustainable communities, cities and regions be developed. According to requirements, the model is flexible enough to implement individual strategies in greater detail, without destroying the holistic and overall strategy. The expert system addresses the approach of new urbanism: walkability, connectivity, mixed-used-density, mixed housing, increased density where useful, green transportation and sustainability.

6 ABSTRACT

Zur Realisierung Green bzw. Low Carbon Cities zeigen wir individualisierbare Wege auf, diese Ziele mit intelligenten Systemen + motivierten Bewohnern für Städte unterschiedlicher Entwicklungsstadien und Reifegrade zu erreichen. Mit der 3. Generation von Sustainable Development können Green Cities jenseits tradierter industriegesellschaftlicher Planung nachhaltig befördert werden. Green oder Low Carbon Cities bedürfen prozessorienterter Ziele, wie sie auf der Basis von Kultivierungsfeldern möglich werden.

Ein Denken in Lebenszyklen von Bauwerken, Infrastrukturen und Technologien führt idealerweise zu einer Mosaik-Zyklus-Kultur, in der unterschiedliche Entwicklungs- und Reifestadien nebeneinander einen kontinuierlichen Verbesserungsprozess ermöglichen.

Unter dem Begriff „4thNature“ denken wir Ambient Assisted Urban Resources zusammen.

7 URBANE METABOLISMEN

Weltweit werden große Anstrengungen unternommen, Green bzw Low Carbon Cities zu realisieren. In diesem Beitrag werden individualisierbare Wege aufgezeigt, diese Ziele mit intelligenten Systemen und motivierten Bewohnern für Städte unterschiedlicher Entwicklungsstadien und Reifegrade zu erreichen. Damit zeigen wir Perspektiven auf, wie Green Cities jenseits tradierter industriegesellschaftlicher Planungen (die ja Planungen des fossilen Zeitalters waren) nachhaltig befördert werden können.

Bevor Konzepten für künftige Veränderungen entwickelt werden, empfiehlt sich eine Ursachenanalyse:

Warum haben sich in der fossilen Ära so energieintensive Metabolismen herausgebildet?

- In alten Industrieländern?
- In Schwellenländern?
- In Megacities?

“Von den fünfziger Jahren an erfuhren der Energieverbrauch, das Bruttoinlandprodukt, der Flächenbedarf von Siedlungen, das Abfallvolumen und die Schadstoffbelastung von Luft, Wasser und Boden den für die heutige Situation entscheidenden Wachstumsschub. Die Gesamtheit der damit einhergehenden tiefgreifenden Veränderungen der Produktions- und Lebensweise wird als ‘1950er Syndrom’ bezeichnet.” (Pfister 1996) Die These des 1950er Syndroms postuliert mit den 1950er Jahren eine Epochenschwelle, welche unsere Zeit von weniger zerstörungsdynamischen Evolutionsformen des Mensch-Umwelt Verhältnisses trennt und betrachtet den langfristigen Rückgang der relativen Energiepreise in der 2. Hälfte des 20. Jhdts als eine der wesentlichen Triebfedern der seitherigen Entwicklung.

Die damit einhergehende energetische ‚Überdüngung’ unserer Städte hat diese Siedlungstrukturen insgesamt geprägt. Diese Prägung wird durch einen Umstieg auf Erneuerbare Energien nicht wie von Zauberhand verschwinden, sondern langwierige metabolistische Veränderungsprozesse erfordern.

8 SUSTAINABLE DEVELOPMENT 3.X

Ebenfalls gilt es, nachhaltige Entwicklung‘ nicht als etwas statisches, konzeptionell Fertiges zu sehen. Seit dem 18. Jahrhundert hat die Interpretation von „Nachhaltigkeit verständlicherweise Wandlungen erfahren. Sustainable Development ist, nach Generationen gegliedert, deutlich besser operationalisierbar.

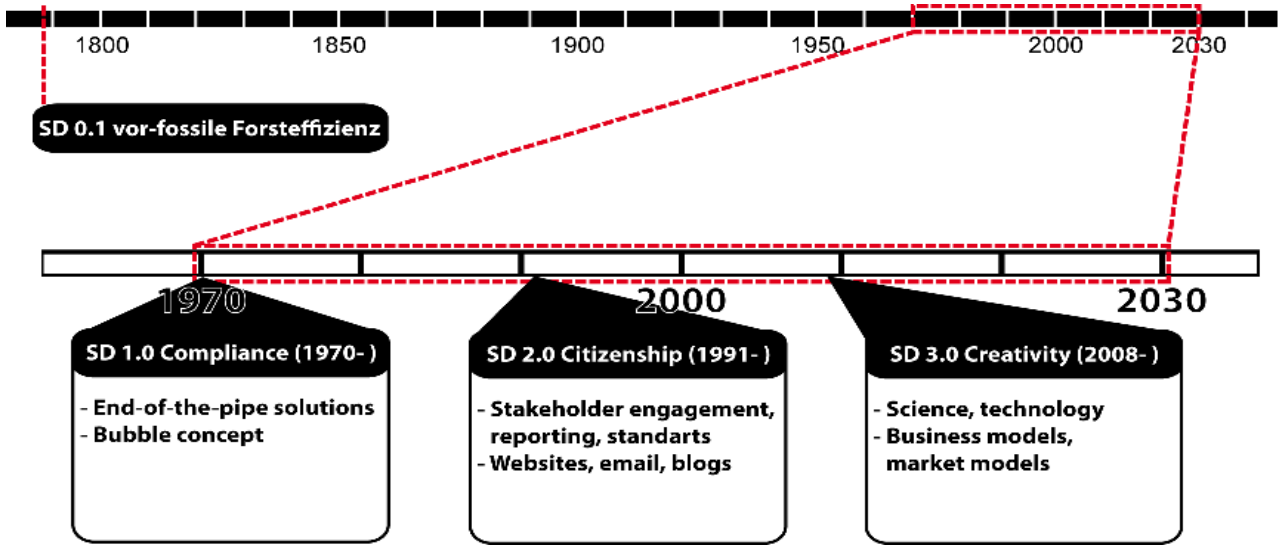

Fig. 1: Sustainable Development-Generationen Pietsch 2009

So sollte mit dem begrifflichen Ursprung in der vor-fossilen Zeit die Holzproduktion optimiert werden, im Ergebnis enstanden aber nicht nachhaltige Forsten.

Nach dieser Latenzphase SD 0.1. „Früh-Neuzeitliche Forstwirtschaft“ kann die Anfang der 70er Jahre des vergangenen Jahrhunderts beginnende Generation 1.0 auch als Pionierstadium interpretiert werden. Die Generation 2.0 entspricht dem, was nach Rio 1992 im Bewusstsein von Planern/-innen als Nachhaltigkeitsparadigma verankert ist.

Inzwischen, spätestens seit der 2007 beginnenden Finanzkrise, haben wir es mit der 3. Generation zu tun. In dieser Generation wird Sustainable Development vom Neben- zum Mainstreamphänomen. Für Politik, Wirtschaft und Gesellschaft wird SD im Kontext von Klimawandel und der Endlichkeit fossiler Ressourcen zur selbstverständlichen Realität, während der Planerstand noch mit den vergangenen Konzepten jongliert.

Bisherige und künftige Entwicklungen lassen sich auf einer Zeitachse angemessen veranschaulichen:

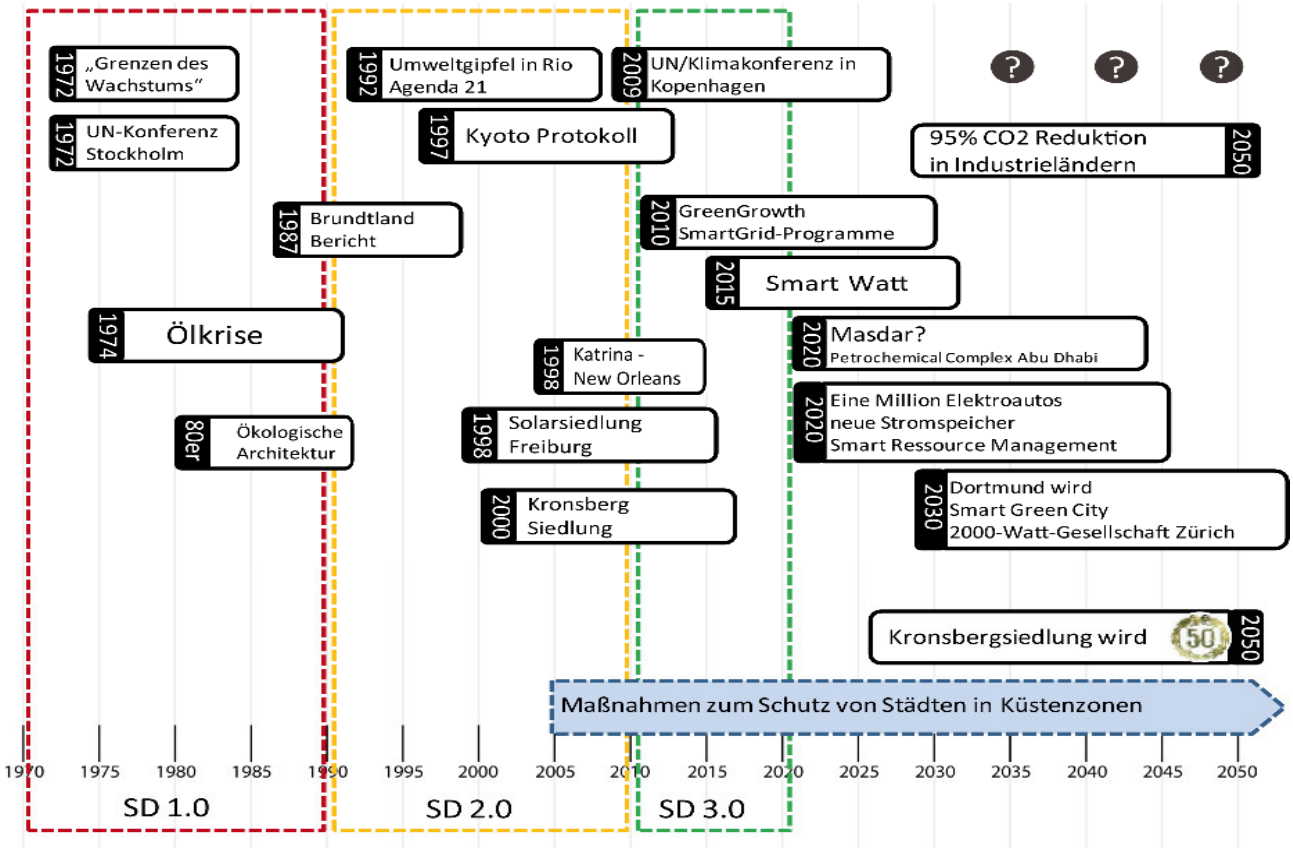

Fig. 2: Milestones auf dem Weg zu ‚Green Cities‘ Pietsch 2009

Wir gehen davon aus, das die ‚Kultivierungsfelder’:

- Postfossiles Ressourcenmanagement,
- Wissensgesellschaftliche Raum- und Infrastrukturen und
- Gesellschaft und Kulturen

geeigneter sind, nachhaltige Entwicklung zu operationalisieren als die traditionellen Säulen Ökologie, Wirtschaft und Soziales.

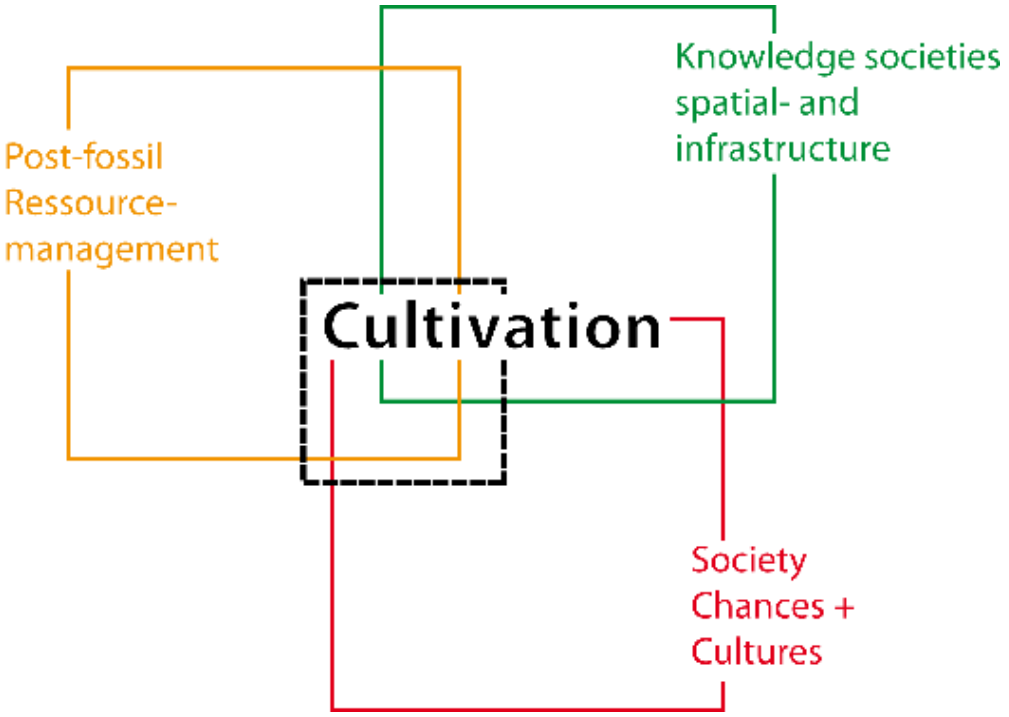

Fig. 3: Kultivierungsfelder Pietsch 2003

9 ZIELE UND OPERATIONALISIERUNGEN

Green oder Low Carbon Cities bedürfen prozessorienterter Ziele, wie sie auf der Basis der Kultivierungsfelder möglich werden.

Das im Umfeld der ETH Zürich konzipierte Konzept der „2000-Watt-Gesellschaft“ stellt sicher eine besser begründete Zielgröße dar als diffuse sogenannte Klimaschutzprogramme. Aber auch hier bedarf es ganzer Bündel von Lösungen, um diese Zielgröße zu operationalisieren.

Die angestrebte Energiewende stellt eine große technologische wie gesellschaftliche und kulturelle Herausforderung dar, die in ihrer Größenordnung mit einer neuen industriellen Revolution vergleichbar, mindestens aber als nächster Kondratieff-Zyklus zu interpretieren ist. Diese „Revolution“ kann nur gelingen, wenn dazu erheblicher Forschungs- und Entwicklungsaufwand betrieben wird. Dies betrifft sowohl die erneuerbaren Energieträger, die Infrastruktur, die Technik zur effizienteren Energieverwendung als auch die Bereitstellung des Wissens über Erhalt und Erweiterung von natürlichen Kohlenstoffvorräten und Senken.

Über die Hälfte des heutigen Bruttoenergieverbrauches werden direkt oder indirekt für die Erstellung und den Betrieb von Bauten benötigt - alleine 60% davon für den Wohngebäudebereich.

Die tradierten Siedlungsflächen-Typisierungen sind längst nicht mehr hinreichend, erst recht nicht für Green City-Konzepte. Hier schlagen wir eine vielfältige Kulturlandschaft aus „urbanen Ressourcenfeldern“ vor. Öffentliche und private Grünflächen fungieren zugleich auch als Ressourcenfelder für urbane Landwirtschaft, Urban Forests, Biomasse-Produzenten und Areale eines intelligenten Wassermanagements. Diese Ressourcenfelder sind ökosystemar zu verknüpfen, da der Umwandlungsprozess eine ökosystemare Betrachtungsweise erfordert, keine ressourcenverzehrende Plantagenwirtschaft wie bisher.

Ein Denken in Lebenszyklen von Bauwerken, Infrastrukturen und Technologien wird idealer-weise zu einer Mosaik-Zyklus-Kultur zur Bewirtschaftung urbaner Ressourcenfelder führen, in der unterschiedliche Entwicklungs- und Reifestadien nebeneinander einen kontinuierlichen Verbesserungsprozess ermöglichen. Ein Denken, welches bei Planungen wie für die Laborstadt Masdar noch nicht zu finden ist. Klimatisier-ungstechnologien unterliegen einem anderen Life-cycle als die Bauwerke, in denen sie eingesetzt werden. Die meisten der heute für Bauen, Wohnen oder Verkehr propagierten Nachhaltigkeitstechnologien sind Übergangstechnologien und werden in kurzen Abständen weniger Jahre noch mindestens bis zur Mitte des Jahrhunderts immer wieder durch bessere abgelöst. Damit notwendig zu verbinden ist ein anderes Verständnis von (Stadt-) Planung, welches das industriegesellschaftlich-fossile Denken überwindet, nicht nur ‚ideale’ Zustände fixieren will.

Eine Umfrage unter Raumexperten/-innen, durchgeführt vom Forum Wissenschaft & Umwelt im Oktober 2009, verdeutlicht leider, dass ausgerechnet die Fachcommunity die anstehenden Veränderungen und ihre metabolistischen Ursachen noch nicht antizipiert hat.

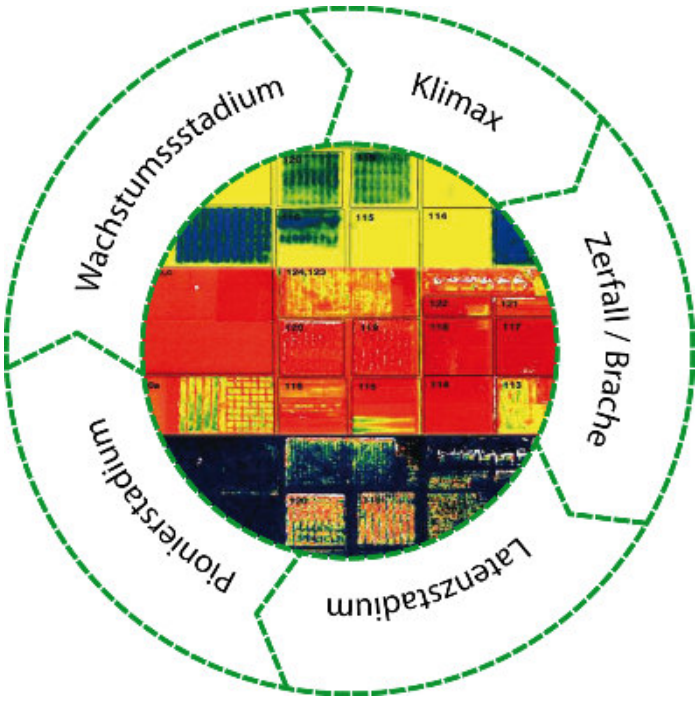

Fig. 4: Mosaik-Zyklus-Kultur zur Bewirtschaftung urbaner Ressourcenfelder Pietsch 2010

10 4TH NATURE

In Green Cities werden Wasserver- und Entsorgung sowie Speicherung, die Energiesysteme durch ein intelligentes, nutzeroptimiertes Ressourcenmanagement organisiert sein, dessen technologische Basis in diversen „Ubiquitous City"-Konzepten vorgedacht ist. Unter dem Begriff „4thNature" denken wir solche Ambient Assisted Urban Resources zusammen.

Zur Dimension: Cisco-Chef Chambers rechnet im Kontext von Smart Grids mit einem 10x höheren Geschäftsvolumen allein für das Internet der Energie. Korea hat am 25. Jan. 2010 eine bis 2030 reichende Nationale Smart-Grid- Roadmap definiert und will damit 500.000 neue Arbeitsplätze generieren.

All dies wird Auswirkungen auf die Gestalt der Städte, die Morphologie der Quartiere haben. Standorte, Klimazonen und Traditionen sollten individuelle Ausprägungen jenseits der vor-herrschenden ‚alles ist möglich', egal wo Haltung ermöglichen. Ein besonderes Augenmerk, auch in gestalterischer Hinsicht, wird den vielfältigen Energiespeichern zu widmen sein. Ein Ergebnis könnte als angemessenes Planungswerkzeug ein Navigationssystem für Roadmaps hin zu Green Cities sein.

Im 4thnature-lab des i-environments-Team der HCU Hamburg werden wir solche Werkzeuge entwickeln und erproben.

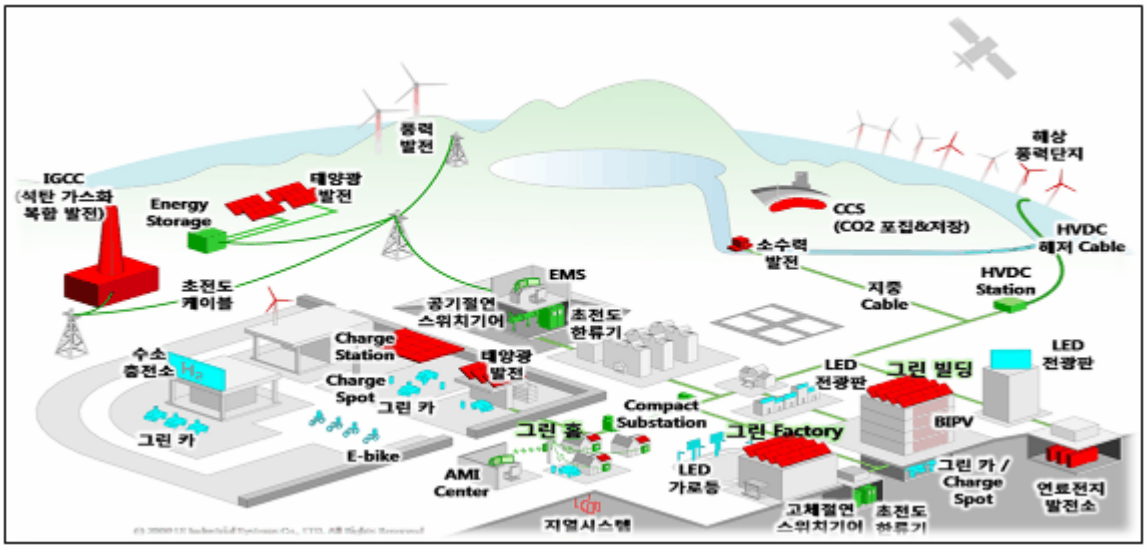

Fig.5: Smart Grid Korea

11 WISSENSAREALE ALS PIONIERE

Ideale Pioniere, um Low-Carbon-Prozesse im urbanen Raum zu erproben und zu testen, sind Wissensareale mit ihren ‚Nutzern'. Wer sonst, wenn nicht gut gebildete, lernprozessaffine Menschen sind als Verhaltens-pioniere geeignet? Dementsprechend befinden sich weltweit viele Universitäten in einem fruchtbaren ‚Sustainable Campus'-Wettbewerb. Als positives Beispiel kann das EAWAG-Gebäude in Dübendorf bei Zürich dienen. Dort erprobte Formen und Techniken im Umgang mit Energie und Ressourcen können dann in andere Stadtquartiere diffundieren.

Thesen:

- Intelligente Ökosysteme werden als „vierte Natur" von urbaner High-tech-Land- wirtschaft über Green IT bis hin zu Smart Grids ein wesentlicher Bestandteil nachhaltiger urbaner Kultivierungen sein.
- Die zu Green Cities führenden Trends und Tendenzen weisen über ‚Stadtplanung' bisheriger Praxis weit hinaus.
- Neue Wertschöpfungen, neue Akteure und Akteurskonstellationen, neue Technologien, aber auch neue (Wert-)Maßstäbe werden zu global hoffentlich vielfältig differenzierten Kultivierungen unserer Städte führen.

Dieser Beitrag ist ein Arbeitspapier des 4thnature-lab im i-environments-team der HCU Hamburg.

1 ABSTRACT

A diagnosis tool for small and medium sized cities on their way to an InnoCité

Kleine und mittlere Städte im Einflussbereich von Agglomerationen stehen vor der Aufgabe Strategien entwickeln zu müssen, um in dem vielschichtigen kommunalen Konkurrenzfeld bestehen zu können. Dabei ist es für die lokalen Akteure und Entscheidungsträger der Stadt- und Regionalentwicklung wichtig, eine zielgerichtete Situationsanalyse der Stadt und ihrer Einbindung in den Verflechtungsraum vornehmen zu können, ohne Datenfriedhöfe anzulegen. Diese Situationsanalyse soll es den Akteuren erlauben, schnell die wesentlichen Handlungsfelder und zentralen Stellschrauben für Veränderungen auszumachen. Vor dem Hintergrund, dass gerade in kleinen und mittleren Städten die Beobachtung gemacht wird, dass aufgrund der Ausstattung der Verwaltungen tagesaktuelle Aufgaben im Vordergund stehen und der Gesamtzusammenhang bzw. die Einbindung in eine integrierte Entwicklung darunter leiden, ist es essentiell, ein einfaches, transparentes und praxistaugliches Diagnoseinstrument zu entwickeln.

Die Partnerschaft des INTERREG IV B Projektes InnoCité im Alpenraum hat ein solches Diagnosemodell entwickelt und testet dieses derzeit in sieben Pilotregionen, auch um Hinweise für eine Überarbeitung des Tools zu sammeln. Dabei orientiert sich das Diagnosemodell an dem Ziel eine möglichst hohe Lebensqualität für die Bürger zu gewährleisten. Daher werden die Bereiche Beschäftigungssituation, Bildung, Wohnungswesen, Versorgungssituation, Erreichbarkeiten, Soziales Leben und Erholung abgebildet.

In dem Vortrag soll zum einen der Weg zu dem konsensualen Diagnosemodell der InnoCité-Partnerschaft beschrieben, das Modell selber dargestellt und erste Testergebnisse präsentiert werden.

2 DAS PROJEKT INNOCITÉ

2.1 Ziel der Projektpartnerschaft

Zunehmende gesellschaftliche, ökonomische und ökologische Veränderungen stellen die Kommunen vor neue Herausforderungen. Einhergehend mit sinkenden kommunalen Finanzmitteln, die den Handlungspielraum insbesondere kleiner und mittlerer Städte einschränken, gilt es innovative Lösungsstrategien zu entwickeln, um im kommunalen und regionalen Konkurrenzfeld bestehen zu können. Kleine und mittlere Städte, die im Verflechtungsbereich von Agglomerationen verortet sind, sehen sich einem besonderen Wettbewerbsdruck gegenüber den Agglomerationen ausgesetzt. Die überregionale Bedeutung von Agglomerationen als Arbeits-, Wohn- und Versorgungsstandort kann einerseits positive Auswirkung auf die Entwicklung von Kommunen haben. Andererseits birgt die geringe Distanz zu den Agglomerationen ein hohes Risiko des Bedeutungsverlustes als eigenständiger Wirtschafts- und Versorgungsstandort.

Innovative Strategien sollen die kleinen und mittleren Städte unterstützen sich im Gesamtraum zu positionieren, Vorteile, die sich aufgrund der Nähe zu den Agglomerationsräumen bieten, zu nutzen sowie Nachteile der Nähe zu minimieren. Dabei sollen die entwickelten innovativen Strategien an das endogene Potential der Städte und Regionen anknüpfen, eine möglichst hohe Lebensqualität gewährleisten und den Maximen der nachhaltigen europäischen Stadt, die in der Leipzig Charta[1] verankert sind, entsprechen. Unter der Einbindung lokaler Schlüsselakteure soll das Bewußtsein für die Stärken der Region geschaffen werden. Um an die Stärken anzuknüpfen und den Herausforderungen begegenen zu können, müssen diese ermittelt werden. Am Anfang des Projektes InnoCité steht deswegen die Erarbeitung eines Diagnosetools, das die wesentlichen Handlungsfelder offenbaren soll, an denen mittels der Entwicklung innovativer Strategien angeknüpft werden kann.

[1] Vgl. http://www.eu2007.de/de/News/download_docs/Mai/0524-AN/075DokumentLeipzigCharta.pdf, letzter Zugriff am 24.02.2010

An dem INTERREG IV B Projekt InnoCité sind acht Projektpartner aus den Ländern Frankreich, Italien, Slowenien, Österreich und Deutschland beteiligt.[2] Der Lehrstuhl Regionalentwicklung und Raumordnung, der Technischen Universität Kaiserslautern, übernimmt im Unterauftrag des Bayerischen Staatsministeriums für Wirtschaft, Infrastruktur, Verkehr und Technologie die Federführung des Workpackage 4, in dem die Erarbeitung eines solchen Diagnosetools wesentlicher Bestandteil ist.

2.2 "Positionsbestimmung" mit Hilfe eines Diagnosetools

Diese Herausforderungen stellen in erster Linie lokale Akteure und und Entscheidungsträger der Stadt- und Regionalentwicklung vor immer komplexer werdende Fragestellungen und Entscheidungsprozesse, die es im Sinne einer nachhaltigen und zukunftsorientierten Stadt- und Regionalentwicklung zu lösen gilt.

Problemlösungen sowie eine aktive Gestaltung von Herausforderungen setzen voraus, dass diese bekannt sind und an den richtigen „Stellschrauben" gedreht wird, um einen anderen Weg einzuschlagen. Nicht immer sind Ursachen für Veränderungen offensichtlich oder erschließen sich von allein. Dementsprechend ist es vorteilhaft bzw. notwendig verschiedene Themenfelder in einer Untersuchung, die sich mit den kommunalen Entwicklungen und Herausforderungen beschäftigt, zu betrachten.

An dieser Stelle kann die Frage gestellt werden, warum der Bedarf an einem solchen Diagnoseinstrument überhaupt besteht. Einerseits hat sich im Rahmen der Forschungsarbeiten des Lehstuhls Regionalentwicklung und Raumordnung an der Technischen Universität Kaiserslautern im Bereich der regionalen und kommunalen Entwicklung sowie in der Zusammenarbeit mit lokalen Akteuren gezeigt und bestätigt, dass:

- lokale Entscheidungsträger zwar die Stärken und Schwächen in ihrem Arbeitsschwerpunkt kennen, allerdings der interdisziplinäre und intersektorale Zusammenhang oft vernachlässigt oder nicht gesehen wird;
- langfristige sich anbahnende Entwicklungen vor dem aktuellen Tagesgeschäft in den Hintergrund treten[3];
- die Relevanz und Auswirkungen der Entwicklungen in vielen Bereichen nicht offensichtlich sind bzw. nicht in ihrer Gesamtheit erkannt werden;
- die Stärken der Kommunen/Regionen von lokalen Akteuren oft falsch eingeschätzt werden, d.h. frühzeitiger Handlungsbedarf die Stärken auszubauen zu spät erkannt wird.

Andererseits erfordern Motive, wie beispielsweise Kosten- und Personalaufwand, die Entwicklung eines einfach anwendbaren Diagnosetools für lokale Akteure und Entscheidungsträger.

Vor dem Hintergrund der Verbesserung der Wettbewerbsfähigkeit von kleinen und mittleren Städten im Alpenraum, die im Verflechtungsbereich von Agglomerationen liegen, ist im Rahmen des INTERREG IV B Projektes „InnoCité" ein solches Diagnosetool von der transnationalen Partnerschaft erarbeitet worden. Ziel ist es, lokalen Akteuren und Entscheidungsträgern die Möglichkeit zu eröffnen, eine zielgerichtete und querschnittsorientierte Situationsanalyse durchzuführen. Eine einfache Handhabung des Diagnosetools und ein minimaler Daten- und Erhebungsaufwand soll gewährleisten, dass die Anwendung mit einem geringen Finanz- und Personaleinsatz für die Kommunen verbunden ist.

2.2.1 Methodische Vorgehensweise

Folgende Leitfragen haben bei der Entwicklung des Diagnosemodells im Vordergrund gestanden:

- Wie stellt sich die Situation des Untersuchungsraumes im Vergleich zur Agglomeration dar?,
- Wie ist der Untersuchungsraum mit der Agglomeration verflochten?,
- Wie ist der Untersuchungsraum derzeit aufgestellt (Lebensqualität)?.

Im Sinne der Definition einer InnoCité und um die thematische Offenheit der Ergebnisse zu gewährleisten ist den oben angeführten Leitfragen das Thema „Lebensqualität" zu Grunde gelegt worden.

[2] Das Projekt wird konfinanziert durch den Europäischen Fonds für Regionale Entwicklung.
[3] Ein gutes Beispiel hierfür ist die demographische Veränderung von Kommunen, die sich vielerorts über einen langen Zeitraum entwickelt hat, aber erst mit dem „sichtbar" werden von lokalen Akteuren ernsthaft wahrgenommen und thematisiert wird.

„Lebensqualität ist als multimediales Konzept zu verstehen, welches materielle und immaterielle, objektive und subjektive, individuelle und kollektive Wohlfahrtskomponenten gleichzeitig umfasst."(Vgl. Huschka D., Wagner G.G., S. 2). Der äußerst abstrakte Begriff der Lebensqualtität kann sich häufig nicht den fachspezifischen Hintergründen der Forschung entziehen. Beispielhaft sei hier das Indikatoren-System zur nachhaltigen Entwicklung in Deutschland, 2008 oder die Indikatoren des Österreichischen Lexikon der Nachhaltigkeit[4] angeführt, das Lebensqualität mit Indikatoren, wie beispielsweise:

- Einkommensverteilung,
- Eigene Gesundheitswahrnehmung, nach Einkommensniveau,
- Beschäftigungswachstum, etc.

misst und beurteilt. Eine Vielzahl von Indikatoren, die das Niveau der Lebensqualität abbilden wollen, messen Indikatoren des Lebensstandards[5] und Wohlfahrtsindikatoren und/oder sind an fachspezifische, übergeordnete Themenbereiche/Auftraggeber gebunden.

Das Diagnosetool ist nicht darauf ausgelegt die vorhandene Lebensqualität zu erheben und zu beurteilen, was sich aufgrund dafür notwendiger qualitativer empirischer Analysen schwierig gestalten dürfte. Mittels des Diagnosetools soll daher geprüft werden, ob die Grundvoraussetzungen für eine hohe Lebensqualität im Untersuchungsraum vorhanden sind.

Im ersten Schritt des Erarbeitungsprozesses sind von den Projektpartnern die Grundvorausetzungen für Lebensqualität definiert worden, an denen die zu betrachtenden Bereiche anknüpfen. Es wird von der Annahme ausgegangen, dass Lebensqualität eng mit den Grunddaseinsfunktionen verknüpft ist, d.h. mit der Befriedigung der Grunddaseinsfunktionen wächst die menschliche Zufriedenheit und somit steigert sich die Lebensqualität. Aus diesem Zusammenhang heraus sind folgende Themenbereiche in dem Diagnosetool besonders berücksichtigt worden:

- Beschäftigung,
- Wohnungswesen,
- Versorgungssituation (inklusive soziale und technische Versorgung, Einzelhandel),
- Soziales Leben,
- Erholung,
- Mobilität / Erreichbarkeiten

und im Rahmen des Projektes InnoCité gewichtet worden.

Als nächsten Arbeitsschritt sind aus den einzelnen „Lebensqualitäts-Bereichen" Schlüsselindikatoren entwickelt bzw. abgeleitet worden, die in einem Abstimmungsprozess mit den Projektpartnern diskutiert und beschlossen wurden. Die erarbeiteten Schlüsselindikatoren sind den oben angeführten Leitfragen zugeordnet, denn eine Erhebung aller Indikatoren für die Agglomeration und dem Untersuchungsraum erwies sich in diesem Kontext als nicht sinnvoll.

2.2.2 Das Diagnosetool im Überblick

Neben der quantitativen Datenabfrage im Diagnosetool, sind ebenfalls qualitative, ergebnissoffene Fragen zu einzelnen Themenbereichen eingearbeitet worden. Ziel dieser qualitativen Erhebung ist es, dass der Nutzer ebenso Einschätzungen zu bestimmten Themenbereichen sowie deren Entwicklung geben kann. Mit der Mischung aus quantitativer und qualitativer Erhebung von den Indikatoren soll erreicht werden, dass sich der Nutzer des Diagnosetools neben den „harten" Fakten ebenso Gedanken zur derzeitigen und künftigen Entwicklung macht. Es geht bei dem Diagnosetool nicht nur um die Abarbeitung einer vorgegebenen Reihe von Fakten, die anschließend mit den polarisierenden Begriffen „Ja" / "Nein" und „gut" / „schlecht" versehen werden können. Vielmehr soll bei den Nutzern eine Sensibilität für die Entwicklungen, auch fachfremder Bereiche geweckt und die interdisziplinäre Kommunikation angeregt werden. Des Weiteren

[4] http://www.nachhaltigkeit.info/artikel/indikatoren_lebensqualitaet_747.htm, letzter Zugriff am 24.02.2010
[5] Niveau der Lebenshaltung, bezogen auf einen Raum und die Gesamtheit seiner Bewohner oder auf einzelne Gruppen oder Individuen. (H. Leser, S. 508)

kann das Diagnosetool, wenn es einfach und transparent gehalten werden soll, nicht alle Entwicklungen detailliert erfassen. An dieser Stelle kann sicherlich kritisiert werden, dass in diesen Bereichen keine objektive Darstellung der Sachverhalte möglich ist. Allerdings bildet das Diagnosetool einen Ausschnitt der wichtigsten zentralen Handlungsfelder ab, der durch subjektive bzw. untersuchungs-raumspezifische Ergänzungen erweitert werden kann. Durch die Einschätzungs- und Ergänzungsfelder wird die Identifizierung des Nutzers mit der Analyse erhöht, da er sich in den Themenfeldern abseits der datenbasierten Indikatoren wiederfinden kann. Ebenso entspricht dies der Tatsache, dass sich Lebensqualität nicht nur anhand einer statistisch-basierten Strukturanalyse wiedergeben lässt, sondern auch vom subjektiven Empfinden abhängig ist.

Das Diagnosetool ist in zwei Abschnitte gegliedert. Im ersten Abschnitt werden Daten und Einschätzungen zur Agglomeration abgefragt, die insbesondere bei der Bewertung der derzeitigen Situation des Untersuchungsraumes eine wichtige Rolle spielen. Im foldengen sind Bereiche der Erhebung sowie die Indikatoren dargestellt:

- Bevölkerungsentwicklung (Anzahl, Wachstum, Altersverteilung, Wanderungen, etc.),

INDICATOR	UNIT (collectable, comparable, measureable)	RELEVANCY
Basic data for the metropolis		
Population status quo and development		
Population in number of inhabitants	Number of inhabitants per year, 1991 - 2007	Size and importance of the metropolis
Population forecast	Percentage from 2000 till 2020	Assessment of the due to population challenges
Age distribution	Percentage, 2007 class divided in: under 18 years, 18 till 65 years, over 65 years	Metropolis affected by an aging population and the consequences
Development of migration (moving in and moving out)	Number of people moving in and out, 1991 - 2007	Attractiveness of the metropolis as location for living and working
Population density	Number of inhabitants per sqkm, 2007	Urbanity of the metropolis

- Wirtschaftliche Situation (BIP, Arbeitslosigquote, FuE-Einrichtungen, Immobilienmarkt, etc.),

Economy		
Gross domestic product	€ per person, 2007	Economical capacity
Gross value added	€ per person, 2007	Economical capacity
	per economical sector, 2007	Economical powers of the sectors
Average household income	€ per household, 2007	Economical situation of the inhabitants
Purchasing power per household	€ per household, 2007	Economical capacity of the inhabitants
Unemployment rate	Percentage, 2007	Assessment of the employment market
Real estate market	Price for living space in € per sqm, 2007	Price levels as reasons for migration of persons, enterprises
	Price for office space in € per sqm, 2007	
	Price for industrial zone in € per sqm, 2007	

- sowie Verkehrsverflechtungen zwischen Agglomeration und Untersuchungsraum (Anbindung, Pendlerverflechtungen,etc.)

Traffic from / to the metropolis		
Travel time from pilot site to metropolis	By car in minutes per km	Accessibility of the metropolis
	By train minutes per km	
Accessibility of the metropolis by public transport	Frequency of the public transport	Accessibility and intensity of the linkage between metropolis and pilot site
	Number of daily connections	
	Earliest and latest connection between metropolis and pilot site	
Commuter streams	Number of out-commuters of the pilot site to the metropolis	Assessment of the employment market streams, economical importance of the pilot site / metropolis
	Number of in-commuters in the pilot site from the metropolis	
	Number of out-commuters of the pilot site to surrounding cities	
	Number of in-commuters in the pilot site from surrounding cities	

Der zweite Abschnitt des Diagnosetools befasst sich mit dem Untersuchngsraum selber. Hier gilt es detailiert die Entwicklungen in den Bereichen:

- Bevölkerungsentwicklung,

II. Identification of the situation in the pilot site		
Population		
Population in number of inhabitants	Number of inhabitants per year, 1991 - 2007	Size and importance of the pilot site
Population forecast	Percentage from 2000 till 2020	Assessment of the due to population challenges
Age distribution	Percentage, 2007 class divided in: under 18 years, 18 till 65 years, over 65 years	Pilot site affected by an aging population and the consequences
Development of migration (moving in and moving out)	Number of people moving in and out per aging group, 2003 – 2007 (class divided in: under 18 years, 18 till 65 years, over 65 years)	Attractiveness of the pilot as location for living and working for the different aging groups
size of households	Average of persons per household, 2007	Assessment of the social structure and real estate market
Population density	Number of inhabitants per sqkm, 2007	Urbanity of the location, compare to agglomeration

- Wirtschaftliche Situation mit besonderer Berücksichtigung des Einzelhandels und Tourismus,

Economy		
Gross domestic product	€ per person, 1991 - 2007	Economical capacity (in 2007 compared to the metropolis)
Average household income	€ per household, 1991 - 2007	Economical situation of the inhabitants (in 2007 compared to the metropolis)
Educational level	Percentage of high school graduate school leavers, 2007	Assessment of the further potential of the pilot site and relation to the migration for apprenticeship
Employees per sector	Percentage of total employees, 1991 - 2007	Economical structure
Kinds of enterprises	Total number of enterprises, 2007 (class divided in: microenterprise, small-medium enterprise, large scale enterprise)	Assessment of the economical structure and vulnerability
Unemployment rate	Percentage of unemployed, 1991 - 2007	Assessment of the employment market, compare to metropolis
Tourism		
Seasonal times	Month with highest and lowest number of tourists	Assessment of the seasonality
Tourism relevance	Beds per 1.000 inhabitants, 2007	Assessment of the tourism as economical factor, utilization of the touristic infrastructure
	Overnight stays per 1000 inhabitants, 2007	
Secondary residence	Percentage of secondary residence of total inhabitants	Vitality of the pilot site
Commercial offer		
Sales area	Sales area food / non-food in sqm per inhabitant, 1991 - 2007	Structure and development of offer
Stream of purchasing power	Map with inflow/outflow streams of the purchasing power in €	Centrality of the pilot site as retail location
Vacancies in retail	Percentage of vacant space in retail, 2007	Assessment of the need of actions
Catchment area	Map and number of people, 2007	Centrality of the pilot site as retail location

- Erreichbarkeit/Anbindung,

Accessibility		
Car density	Cars per household, 1991 – 2007	Development of the mobility, traffic demand
Public parking spaces in the centre	Public parking spaces per 100 sqm sales area, 2007	Assessment of the parking space offer concerning the retail structure
Modal split	Percentage of traffic volume (class divided in: mobile individual transport, public transport, non-mobile individual transport), 2007	Assessment about the distribution of traffic volume
Public transport connection	Map with public transport connection in surrounding municipalities with frequency and number of connections, 2007	Accessibility of the surroundings by public transport
Internet connection	Percentage of households with internet connection, 2007	Appreciation of progress
	Percentage of households with low / high quality of internet connection (class divided in: Dial up access or ISDN, broad band connection), 2007	Availability and usage of new media

- Versorgung - technische und soziale Infrastruktur,

Services offer / social infrastructure		
Medical care	Number of doctors per 1000 inhabitants, 2007	Assessment of the medical system in the pilot site (offer and demand)
	List of medical specialists, 2007	
	Number of pharmacies per 1000 inhabitants, 2007	
Day care facilities	Number of places in day care facilities per 1000 children under the age of using public education, 2007	Family-friendly
Facilities for elderly	List of special offers for elderly	Assessment of an adequate infrastructure for the demographic change
Post	Availability: Yes / No	Availability of basic service
Bank	Availability: Yes / No	Availability of basic service
Library	Availability: Yes / No	Quality of life
Theatre	Availability: Yes / No	
Cinema	Availability: Yes / No	
Conference Centre	Availability: Yes / No	
Schools	Kind of schools (class divided in: primary and secondary schools)	Local supply with education facilities, centrality of pilot site as education location
	Number of schools	Centrality of pilot site as education location
	Pupils per teacher	Quality of education
Sport facilities	List of sport facilities	Quality of leisure activities
Museums	List of museums	
Administration level	List of administration higher than municipality level	Supra-local relevance of the pilot site

- Erholung / Urbane Situation

Urban situation		
Urban land	Percentage of urban land covered of the surface in 1997 and 2007	Development of land consumption

zu untersuchen, wobei sich die oben definierten Themenbereiche der Lebensqualität in den einzelnen Unterkapitelnversuchen begrifflich anzupassen.

2.2.3 Anmerkungen zum „Entstehungsprozess“

An der Erarbeitung des Diagnosetools, insbesondere der Schlüsselindikatoren sind die acht Projektpartner beteiligt gewesen. Neben den InnoCité-Projektpartnern sind ebenso verschiedene Fachexperten in den Meinungsbildungsprozess integriert worden. Somit hat sich ein großer Pool an unterschiedlichen Meinungen zu den Schlüsselindikatoren und deren Einordnung in die einzelnen Themenabschnitte und Unterkapitel ergeben. Trotz der Darstellung der „Lebensqualität-Bereiche“ und der Einigung auf das Ziel ein thematisch breitangelegtes, offenes Diagnosetool zu entwickeln und fachliche Hintergründe und Belange an dieser Stelle außen vor zu lassen, war es schwer dies im Diagnosetool konsequent umszusetzen.

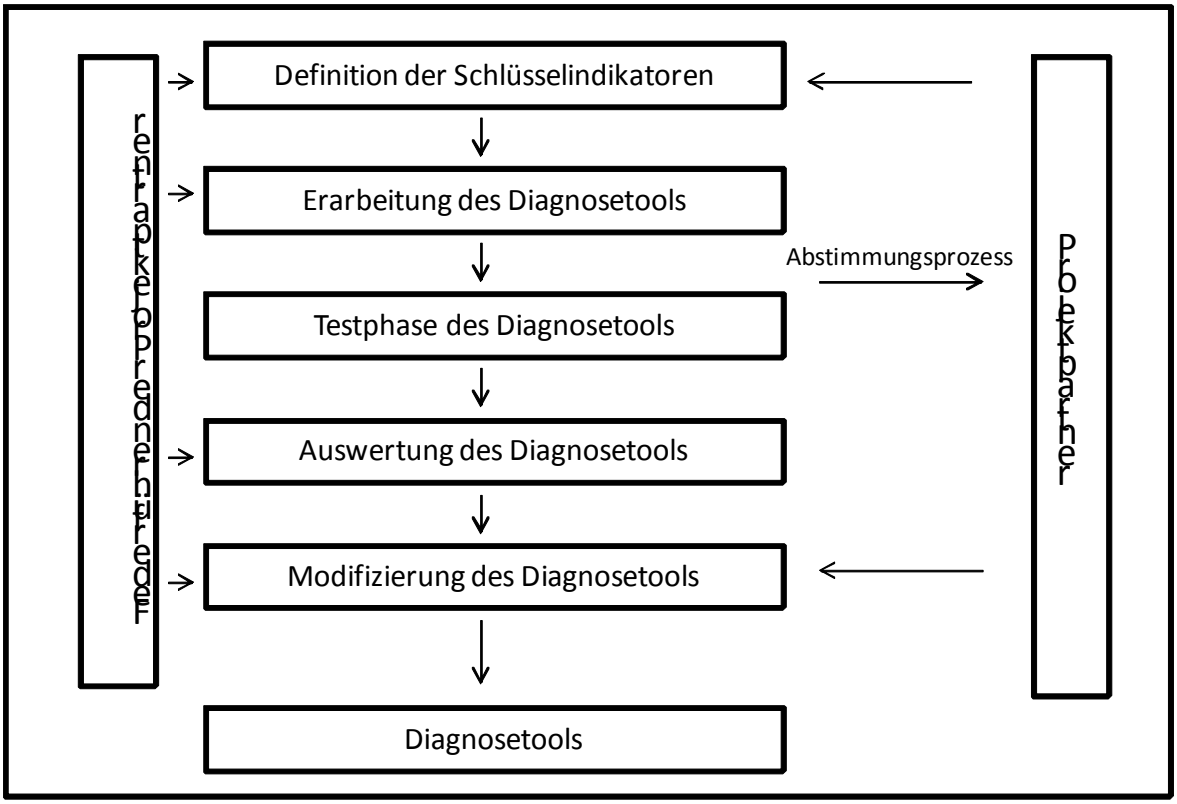

Fig. 1: Erarbeitungsprozess des Diagnosetools

Während des Entwicklungsprozesses zeigten sich ferner zwei Phänomene, die immer wieder das Anliegen eines neutralen und möglichst spektrenreichen Diagnosetools beeinflußten. Einerseits haben für die Projektpartner oftmals Indikatoren im Vordergrund gestanden, die in ihrem beruflichen Umfeld eine fundamentale Stellung einnehmen.[6] Anderseits haben die Projektpartner bereits Vorkenntnisse über die Testregionen und ihre Herausforderungen besessen, in denen das Diagnosetool getestet werden sollte. Diese Regionskenntnisse in Zusammenhang mit möglichen Problemen und Lösungsansätzen haben ebenfalls die Neutralität des Diagnosetools erschwert. Da es sich bei dem Diagnosetool um ein konsensuales Produkt handelt, spiegeln sich die aufgezeigten Phänomene teilweise wider. Ebenfalls erkennbar ist die starke Orientierung auf den Projekthintergrund. Die Fokussierung der innerstädtischen Entwicklung unter besonderer Berücksichtigung der lokalen Wirtschaft, wird beispielsweise darin deutlich, dass dem Einzelhandel und Tourismus mit einem eigenen Unterkapitel der gleiche Stellenwert eingeräumt wird, wie beispielsweise der Bevölkerungsentwicklung oder Wirtschaft.

Sprachliche Barrieren und ein vielfältiges Meinungsbild der Projektpartner haben zu einem längeren Abstimmungsprozess über die Schlüsselindikatoren sowie deren Kategoriesierung beigetragen.

Aus den Erfahrungen zur Entwicklung eines konsensualen Diagnosemodells in transnationaler Zusammenarbeit, lassen sich folgende Empfehlungen festhalten:

- Festlegung einer gemeinsamen Sprache: unklare, mehrdeutige Begriffe vermeiden bzw. in einem Glossar definieren;
- Kreis der beteiligten Personen möglichst überschaubar halten;
- Neutralität in den Köpfen der Beteiligten schaffen, d.h. Hintergrundwissen (problemorientiert, fachspezifisch) abstreifen;
- Nachvollziehbarkeit/Transparenz des Entwicklungsprozesses für alle Projektbeteiligten;
- Begleitung des Entwicklungsprozesses durch einen starken Moderator.

[6] Dieses Phänomen wird von Jung und Schönwandt in ihrem Aufsatz „problems first – eine Sichtweise von Planung und Flächenmanagement“ als die „professionelle Brille“ beschrieben.

3 ERSTE TESTERGEBNISSE

Das Diagnosemodell ist von zehn Pilotstädten in fünf europäischen Landern (Frankreich, Österreich, Italien, Slowenien und Deutschland) getestet worden. Nach dem Vorliegen der ersten Ergenisse, hat sich herausgestellt, dass einige der ausgewählten Indikatoren nicht die erwartete Aussagekraft besaßen. Dies ist zum Teil auf die unterschiedliche Datenlage sowie die Datenqualtät in den einzelnen Länder zurückzuführen.

Nach dem Testdurchlauf und dem Versuch die jeweiligen Testregionen untereinander zu vergleichen sind die Projektpartner zu dem Entschluss gekommen, dass das Diagnosetool entsprechend der Datenverfügbarkeit sowie der Aussagekraft der Indikatoren angepasst und modifiziert werden muss.

Es zeigten sich vor allem vier Hauptproblemfelder die jeweils auf individuelle Art gelöst werden mussten:

In einigen Bereichen sind Begriffe unterschiedlich von den Nutzern des Diagnosetools ausgelegt worden. So ist beispielsweise die Datenerhebung für die Agglomeration in den einzelnen Testregionen für unterschiedliche Flächenumgriffe erfasst worden. Während ein Teil der Partner die städtische Ebene als Grundlage verwendete, bezogen sich andere auf die Regionsebene. Nach Ansicht der Partnerschaft soll sich die Datenerhebung für die Agglomeration auf den metropolen Kern konzentrieren. Mittels einer genauen Definition unklarer Begriffe, können künftig solche Missverständnisse umgangen werden.

Einige Daten und Information sind mittels graphischer Darstellung erhoben worden (z.B. Pendlerströme mit Angaben der Pendlerzahlen). Für einen Teil der Nutzer gestaltete sich die graphische Darstellung schwierig, da entweder kein graphisches Material vorlag bzw. der Arbeitsaufwand zur Erstellung zu hoch gewesen wäre, oder die vorhandene Umsetzung der Datengrundlage in einer graphischen Darstellung keine bzw. nur eine geringe Aussagekraft besitzen würde. In diesen Fällen ist die graphische Darstellung um eine tabellarische Datenabfrage ergänzt worden.

Ausgewählte Indikatoren haben nicht die gewünschten Resultate bezüglich ihrer Aussagekraft erzielt. In diesen Fällen sind neue Indikatoren aufgestellt worden.

Ausgewählte Indikatoren haben in dem Diagnosetool keine Schlüsselfunktion übernommen. Diese, in Frage gestellten Indikatoren sind erneut mit den Projektpartnern diskutiert und abgestimmt worden. Entsprechend der Abstimmungsergebnisse sind die Indikatoren aus dem Diagnosetool entfernt bzw. beibehalten worden.

Im Anschluss ist das Diagnosetool gemäß dem Abstimmungsprozess modifiziert worden.[7]

Das Diagnosemodell muss sich erneut in der Praxis bewähren und gegebenfalls weiterhin überarbeitet werden. Als ein Ergebnis des Projektes InnoCité steht es künftig anderen kleinen und mittleren Städten als Instrument zur Verfügung.[8] Über Rückmeldungen, Anmerkungen und Erfahrungsberichte von weiteren Nutzern des Diagnosetools wären wir dankbar.

4 CONCLUSION

Das entwickelte Diagsnosemodell kann als ein Werkzeug für lokale Akteure und Entscheidungsträger der Stadt- und Regionalentwicklung gesehen werden, das die Stärken sowie die aktuellen und künftigen Herausforderungen für die Positionierung kleiner und mittlerer Städte stärker in das Bewusstsein der lokalen Akteure und Entscheidungsträger rückt. Die Sensibilisierung der Entscheidungsträger sowie das Erkennen von komplexen Zusammenhängen kann durch dieses Instrument gewährleistet werden, wenn sich der Nutzer über seine fachlichen Grenzen herauswagt. Nichtdestotrotz ist das bestehende Diagnosetool als „Prototyp“ zu begreifen, das im Rahmen weiterer Praxistests weiterentwickelt werden sollte. Ebenso müssen im Umgang mit diesem Instrument weitere Erfahrungen im Hinblick auf die Handhabung gesammelt werden. Zwar hat das Diagnosetool seinen ersten Testdurchlauf bestanden, dennoch bleibt offen, wie sich der Umgang von Projektexternen damit gestaltet. Ein weiterer notwendiger Schritt ist die Evaluierung, ob die Nutzer in der Lage sind die Ergebnisse des Diagnosetools zu interpretieren sowie die richtigen Schlussfolgerungen für eine zukunftsorientierte Entwicklung ihrer Kommunen zu ziehen oder ob es gegebenenfalls neben dem Hinweis zur Relevanz der Indikatoren weiterer Interpretationshilfen bedarf.

Im weiteren Projektverlauf von InnoCité werden Instrumente und Strategien entwickelt, die die Wettbewerbsfähigkeit der Testregionen fördern sollen. Diese knüpfen an den Ergebnissen des Diagnosetools

[7] Die dargelegten Änderungen sind bereits in der tabellarischen Abbildung der Indikatoren enthalten.
[8] Das Diagnosetool kann künftig unter www.innocite.eu downgeloaded werden.

sowie einer Stärken-.Schwächen-Analyse der Testregionen an. Unter Einbindung lokaler Schlüsselakteure werden diese Strategien und Instrumente in Form von Pilotprojekten getestet. Dabei stehen die nachhaltige Entwicklung der Untersuchungsräume sowie die Übertragbarkeit der entwickelten Strategien auf andere kleine und mittlere Städte im Vordergrund. Mittels eines partnerschaftlich erarbeiteten Evaluationssystems werden die Pilotprojekte von Beginn an begleitet und auf ihre Ergebnisse, bezüglich der lokalen Auswirkungen und den InnoCité-Zielsetzungen, überprüft. Den Abschluss des Projektes bildet ein „Handbuch“ für lokale Akteure und Entscheidungsträger der Stadt- und Regionalentwicklung, das sowohl Instrumente der Diagnose als auch innovative Lösungsansätze offeriert, um kleine und mittlere Städte hinsichtlich ihrer Attraktivität und Multifunktionalität zu positionieren.

ABSTRACT

The past few decades, have witnessed a theoretical transformation towards acheiving good urban form, which is mainly directed toward a more livable, sustainable, connected urban form. In practice, a reversed orientation toward gated communities and divided cities is taking place. Enclosed planned unit development (PUD) has been centers of concern for city planning and urban theory since the late nineteenth century. The relation between PUD and its contextual urban fabric is a preventive force toward a livable city form, a major part of the problem was the blurring of clear boundaries between settlements. This paper explores the differences and similarities between the contemporary theory of good community and the recent practice of gated communities in greater cairo region new towns. It also investigates how to develop lessons from history and theory to criticize and underpinning future practice of urban liveabilty in contemporary urban practice of gated communities?. It also explores systematically the ways in which these types of developments are collectively reshaping the public and private realms and accordingly shape the livability of the city at large, and wiith particular reference to the experience of a developing country like Cairo metropolitan area in Egypt.

Keywords: Theory versus practice - Gated versus open community - connected versus divided city- liveability - greater cairo region – Egypt

INTRODUCTION

Over the past few decades, Egypt like many other countries in the world, drawn in to a dramatic economic and social change toward free market economy. These changes lead to a transformation in the system of organization and governance and consequencly adabted policies that has reshaped development tools and methodologies and directed the trend of development toward the market privatization, and private sector control on development. This transformation occurred in all development branches, types, levels, especially in urban development.This process of privatization and orientation to private urban governance has begun to make its permanent impacts on the urban form and structure of greater cairo region, creating a new phenomena in micro scale known as gated communities, and in macro scale known as Divided City. this phenomena has reshaped the face of urban life and has a great influences on the evolution of metropolitan area in term of its form and structure causing in a harmful social, economical, cultural, urban effects, which exist in both micro and macro level, and has a harmful effect on urban sustainability and livability.

No doubt that future of Urban life is changing through some strong concepts. gated communities is one of these strong concepts that have the ability to make deeper changes in the built environments of liveability of the Egyptian city. Not only on micro level inside this communities but also on macro level for the entire city. While this is the reality of urban practice of gated communities in egypt, that brought different examples of divide unsustainable cities suffuring from loss of urban liviability. on the other hand, a reversed theoritical trend toward amore sustainable, healthy, and connected city has emerged. This paper, therfore, question whethere the new development pattern is good urban form than the traditional urban forms of egyptian cities and obey contemporary theory of good city form, Or not?. The answer seems yes, however, this is not actually true when looking on the overall macro urban form of these cities. The paper asumes that these new trends in developing new cities would create various urban, functional, social, and economical problems.

Government use of gated communities in Greater cairo region new towns, ignored the traditional princibles of cairo earlier stages urban development. and it ignored the vast amount of theoritical trends about sustainable, healthy, livable, and connected urban form. The matter that explore weakness of spatial stratigies, that adobted by egyptian government for new settelments in the overall point of veiw of the whole city livability, sustainability, social equity. Therfore This Paper Aims at exploring the differences and similarities between theory of good community and recent practice of gated communities in greater cairo region new towns, especially in the relation between city parts and the wholeeness of the city.

Besides, how to develop lesson from history and theory of good city form to criticize and underpinning future practice of urban liveabilty in contemporary urban practice of gated communities?. This research explores systematically the ways in which these types of developments are collectively reshaping the public and private realms and accordingly shape the livability of the city at large, with particular reference to Greater cairo region new towns. getting better understanding of the production of egyptin suburbans new towns, which central on gated communities as a dominant residential morphology in suburban landscape. Stressing the issue of efficiency of public authorities in understanding and directing this phenomena to conferm urban development through a comparison with contemporary theoritecal orientation.

METHODOLOGY

In order to answer these questions, the study first need to define communities in its relation to the city, then compare between open and gated communitie in its relation to the city. Second, study theiories to rediscover the traditional and theoritical relationship between micro and macro city urban form. third, to define the extent to which the urban form in the new cities has been distorted. Thus, answering these queries may be achieved by using documentation and reviewing the literature that touched this echo in historical traditional egyptian city, and theoritical classical and contemporary theories of good city form. Yet, identifying the sustainability, continuity, integrity of the current or future urban form in the new Egyptian cities and indicating the role of internal external relationship open or gated on their liveability are not well covered in academia.

GATED COMMUNITIES AND THE CITY

For the porpose of this paper, we used England Newhorizon project defenition of gated communities:

Walled or fenced housing developments to which public access is restricted, often guarded using CCTV and/or security personnel, and usually characterized by legal agreements (tenancy or leasehold) which tie the residents to a common code of conduct. (Atkinson, R., Blandy, S., Flint, J. and Lister, D. (2004))

Gated communities as a pattern of urban development are physically separate a specific area from its context and create areas that are restricts access inside urban fabric. These patterns of planned unit development have reshaped the relation between micro and macro scale urban product behavior, and have isolated itself out from the overall image of the city, the matter that affected the public life in modern Egyptian cities.

This change in its relation with the city have not only affected the micro urban fabric inside these communities, but also affected the overall patten of the city fabric, that Change macro pattern of the city from connected one to a divided one. Gated communities have affected the overall pattern of development creating city of walls, which lead to a transformation of the urban form that shape the built environment surrounding human live inside the city changing it to merely some zones and walls, that motor paths have penetrated it. Which draws a Frustrating picture for society Caged inside the walls, its parts has been divided from each other and away from the overall image of the city. Gated comunities and its relation to the city, necessitate a theoritical need to discover and explore the relation between micro and macro urban form, what is the need for micro urban form to have a connection and relation with its outer context and the city? what is the need of the city to have its parts to be connected?.

6 A NEED TO A THEORY FOR MICRO-MACRO RELATIONSHIP BEHAVIOUR

In this part a theoritical comparison between both gated and oped urban patten in both way of creating relation with its broader city is Conducted. An analysis through physical, functional, economic, and social interaction should be redicovered. Through three levels: first nature of gated development versus open development, second micro-macro relationship for both cases, finaly, nature of divided patterns versus connected one.

6.1 Nature of gated development versus open development

Throgh analysis its apparent that gated communities usualy try to isolate itself out from its broader city context, so they use lolibobos and col-de-sac as a common tree street pattern. This pattern decreases connectedness and increase isolation from every thing else. while, in the oposite, open communities, usualy try to connect itself with its broader city fabric, so it uses grided and radial as a common network pattern. This pattern increase conectivity and continuity with its broader urban fabric. Increasing relation and

corelation with its context. Gated communities reinforce the splintering of communities with social separation and physical walls Fig. (1). In the suburbs gates are the logical extension of the original "suburban" drive. In the city, gates and barricades are also sometimes called "cul-de-sacization" – a term that reflects the design goal to create out of the existing urban grid a street pattern as close to the suburbs as possible, with the added benefits of control and privacy as well (Blakely and Snyder1998).

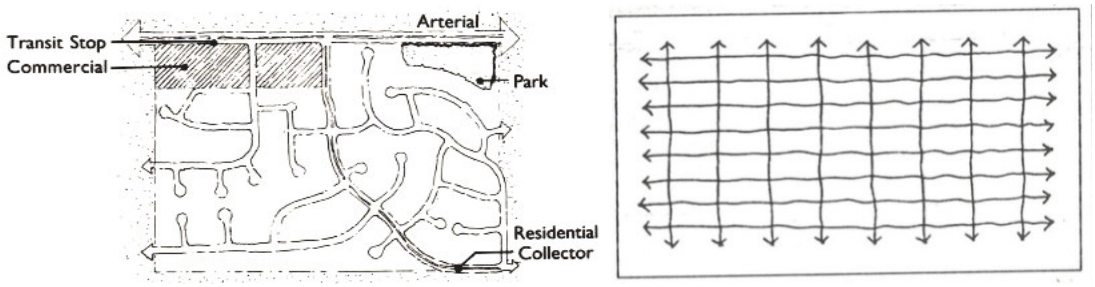

Fig. 1: comparison between grided versus treed street network pattern: Left: Laddered street system. Right: Gridded street system.

Peter Calthorpe, a new urbanist cited that gated communities Physically denotes the separation, and sadly the fear, that has become the subtext of a country once founded on differences and tolerance. Politically it expresses the desire to privatize, cutting back the responsibilities of government to provide services for all and replacing it with private and focused institutions: private schools, private recreation, private parks, private roads, even quasi-private governments. Socially, the house fortress represents a self-fulfilling prophecy. The more isolated people become and the less they share with others unlike themselves, the more they do have to fear. To this extent privatization is a powerful force in the marketplace that directs the home building industry and our land use patterns (Calthorpe, 1993).

Nature of micro-macro relationship of gated development versus open development

Through the formulation of internal pattern, gated or open community interact with its neighbours and with its brouader city. A relation between the new development and its existing context determine its way of social, economical, political, and functional interaction.

Internal pattern of street network and its relation to external surounding discourge or promotoe connectivity and accssibility. Street network blends with adjacent network Fig. (2).Open development Is physicaly connected to each other, so it characterizes in micro level by encourging community, connectedness and integration, foucsing on public releam. While in macro level enable accissilbility, permiability and continuity in the overal urban fabric Fig. (3-a).While gated development is physicaly restricted and isolated from each other and from the overall image of the city, encourge some internal features on the expense of other coasts on macro level. Encourge segregation, not only urban put also functional, social and economical segregation, focusing on the pot-public space features Fig. (3-b).

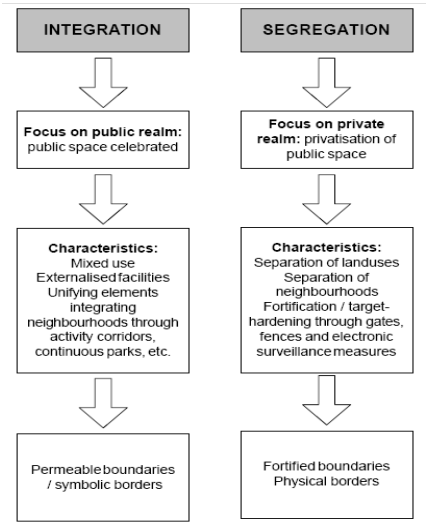

Fig. 2: Application and outcome of integration and segregation approaches to urban design (landman 2006)

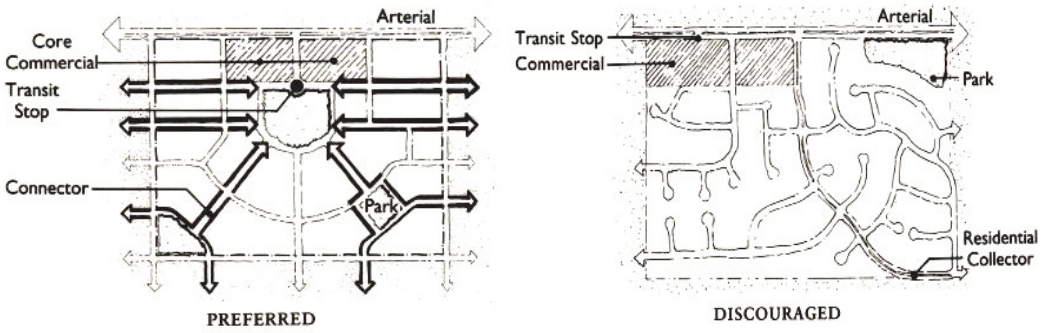

Fig. 3: comparison between gated and open development. Left (A): open communities. Right (B): gated communities.

Nature of divide city development versus connected city development

Private sector through the practicing of gated communities, witnesed a transformation in the structure of city form public road network to a structure of super-block.

Fig. 4: Transformed urban fabric on micro internal scale. Left: Proposed public road network and urban form In new Cairo city macro urban fabric. Right: Transformed road network and urban form In new Cairo city, from public fine grain to a gross urban fabric and a structure of super-blocks

By closing off a large number of neighbourhoods, the existing urban form and road network, are severely affected and transformed. Large areas are now changed into isolated and inaccessible super-blocks, with little resemblance to the original fine-grained urban form. Through-traffic is also limited to a few major arterials that often lead to increase congestion and travel times (Karina landman, 2004). A macro pattern appeared on macro level, divided city, or city of walls Fig. (5).

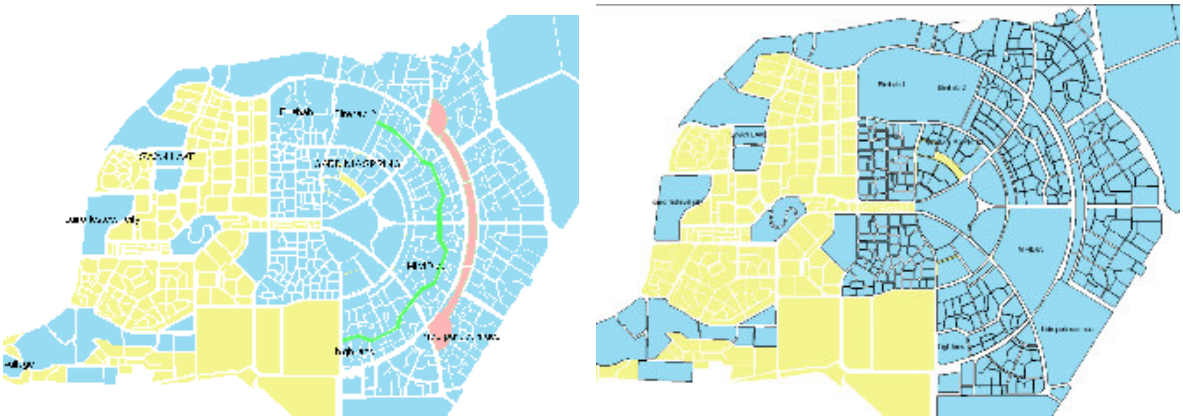

Fig. 5: Transformed urban fabric on macro scale (from connected city to divided city)

This physically separates the specific area from its surrounding environment. It also creates zones or pockets of no/restricted access within the urban fabric, leading to a very coarse grain. In addition, it forces travelers, both motorists and pedestrians, to take an alternative route, hich in many cases can prove to be much longer and more time-consuming. Gated communities, therefore, not only have an impact on the daily activity patterns of people, but also on the urban form and functioning.

CONNECTED CITY AND URBAN LIVIEABILITY

A city's life comes from its connectivity (Dupuy, 1991), Urban connectivity, permeability, integrity are a major echoes in formulating urban liveability. A livable city has to exert a degree of visual, geometrical, functional and path connections. Gated communities a new development pattern has destructed the relation between different parts of the city, destroying the concept of permeability and connectivity, hence remove the liveability from our city Fig. (4).

While Nikos A. Salingaros see that the degree of "life" in a city or region of a city is tied to the complexity of visual, geometrical, and path connections. There is an optimal distribution of connection lengths in a living city, and violating this distribution removes life from the urban environment. Alternative parcellations of a living city reveal the complex structure that is required to generate human contact, which is the basis for city life.(Salingaros 2003).

Gated communities create inaccessibile areas inside urban fabric, reducing the degree to which"ability to access" and possible benefit of services, amenities and urban environment is accessible by as many people as possible. Gated communities creates restrected inaccessibile areas increase the extent to which urban forms restrict movement of people or vehicles in different directions, severing neighbourhoods, reducing Permeability.which discourage movement on foot and encourage longer journeys by car. Street networks should in general be connected. Connected or ‘permeable’ networks encourage walking and cycling and make places easier to navigate through.

gated communities isolate its residents away from every thing, to go any where one must leaf and get out the gate and go on collector road its boundaries just a wall, which pedestrian walks are long, inconvenenient and unsafe, so residents should have there cars for any daily needs increasing car dependency, And generate traffic cognition in the outer city that should harmful to sustainability. Which affect movement pattern of all community in the city, Walking or bycing in the city, become a big problem, to walk from a point to another it talks to longer pathes which consumes more distance and time. Even all passes turned into artaeil roads that donont have any use, only some fences which increae street criminality and reduce sence of safty, hence discourge walkabilbility.

focusing on the development of public transportation as one of the determining element of the sustainable, liveable city, Public transportation, need connected permiable street network, and need accessbility to bus stop isnide these gated gcommunities, which is not acceptable, hence public transportation is not practicale transportation option. Only private car is the available way for moving inside the city, no walking, bycing or public or any alternative transportation options, Only private car.

Gated communities has a big role in reshaping urban life, rather than encourage connectivity and continuity, public rights to reach services amenities and urban space, street liveability, pedestrian, pickles and car alternatives’ and so Support public life in the city, and enforce sence of community. on the contrary, it showed a lot of harmful bad effects not only on the direct environment, but also in the overall image of the city, it impacts city attractiveness, sustainability, continuity, liveability. This would affect social behaviour in new cairo "When people or entire communities turn inward, it forces people to lose a sense of responsibility to their city or region" (Lang and denudes, 1997), “which in the long term threatens values of democracy diversity, class, mobility, and racial integration” Low (2001).

THEORIZING THE MICRO MACRO RELATIONSHIP:

The relation between parts of the city and the overall city is a critical echo in post modern city liveability. Accordingly, Internal external relationship behavior should be discovered. A comparison between classical and contemporary theories of good communities in one hand, and practice of gated communities in the other hand could help to discover this relationship.

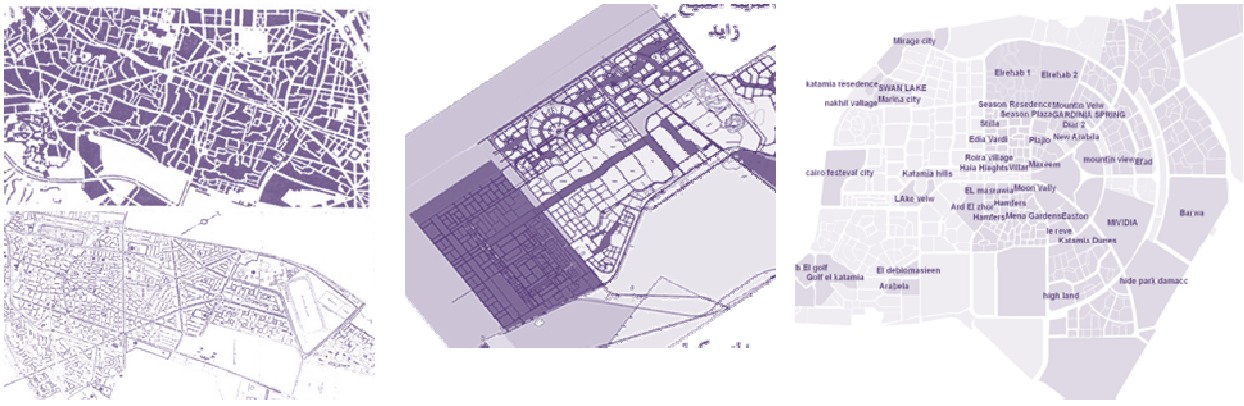
Historical prespective of micro-macro relationship in Egyptian urban form

Looking for typical egyptian city urban form, reveals that a connected pattern is the common form for all historical stages .Throgh history of cairo physical urban form, reminds us of connectivity, permiability, overal socity and community. These characteristics structured the relationship between micro and macro urban form has not seen such a clear division, in historical periods, this type of relationship have witnessed overlay, overlap, connectivity and integration between the micro and macro urban form led to the secretion

pattern of connected cities. This period witnesed practice of gating as a tool for defending against anmies but An important characteristic of these walled cities was that the wall enclosed the entire town or village and therefore served to enhance and emphasize a sense of unity Fig. (7-a).

But as a reaction to modernism which left important marks on our cities, through the evolution in science of roads, and a change to separate land usage patterns, zoning planning depend on a clear separation of land use, urban intensification of densities, modernism recall image of construction, society, community, permanency, and similarity. All were motivated to start thinking about changing this relationship and emerging trend toward neighbourhood implementation. The first half of the twentieth century, have witnesed the first change in the relationship between the micro and macro urban form of the city Fig. (7-b).

In contrast, post modernism lead to deconstruction, ethnicity, locality, pluralism, and diversity. Contemporary cities confronted with a process of privatization of there space. a new stratigies of urban development in zonning depending on planned unit development, reftected contemporary trends in neoliberal deregulatory policy, and contemporary socital change, toward elitism, exclusivity, social class, fear of crime and desire to be protected. This changes lead to loss of public spaces, sence of communitiy, belonging and identity. As a response for all this, developers sought to produce divide urban development units, that seprated totally from the city. Which extends the concept of separation between micro and macro urban form in the city Fig. (7-c).



A: Traditional gridded pattern B: Modern pattern (6 October) C: Post modern post public pattern

Fig. 7: A change from public highly connected micro urban pattern of historic gridded connected towns vs. recent divided postpublic suburban forms of divided city

These recent Change in micro macro relationship of urban form threatened some concepts of good city form like integration, social justice, urban coherence, sense of community, sense of belonging, and public releam. This relation would be discoverd Through a comparison between theoretical classical and contemporary good city form theories, with the reality of practicing gated communities, with particular reference to the role of government in shapeing the practice of this phenomena.

Theoretical perspective:

After discussing the historical prespective of the relation and interaction between micro-macro context in cairo traditional stages of urban development, a theoritecal study through classical theory of good city form of Christopher Alexander (city is not a tree), Kevin lynch (theory of good city form), Jane Jacobs (death and life of great American city), and contemporary theory of good city form of new urbanism, smart growth, livable city, sustainable urban development, should be explored in its veiw to the internal external relationhip.

6.1.1 Classical theory:

Jan Jacobs in The Death and Life of Great American City cited that "Neighborhoods that worked best had no beginnings or ends. A major part of their success depends on their overlapping and interweaving"(Jacobs ,1961). While Kevin lynch in Good City Form cited that "Planning a city as a serious of neighborhoods was either futile or would support social segregation, because any good city has a continuous fabric rather than a

cellular one" (lynch 1980), he stressed on vitality, sense, fit, access, effeciency and justice(lynch1981). He stresses how to make livable environments function at various scales in the city(lynch 1984).

While christopher Alexander cited that City is not a tree “A living city is modeled by a mathematical semi lattice, in contrast to a dead city, which is modeled by a tree. A semi lattice has a vastly larger number of internal connections than a tree of comparable size has. Not only are there many connections in a semi lattice, but there is a great variety of them; by contrast, trees have unique connections. To be liveable, we must advocates a return to more traditional and natural states of place-creation, aplace must generate a sense of belonging in its users, participatory, self-created.

6.1.2 Contemporary theory

International scientific and practical organizations and design movements have published its manifestos and conferences to shape practical theories about good and livable communities, A Livable City, New Urbanism, Smart Growth, and Sustainable Urban Form.

New urbanism, has pointed out the many ways that gated communities are flawed. To many proponents of New urbanism, gated communities are the antithesis of their vision. The principles of New Urbanism range from a single building to an entire community, and strive to build communities that are public, interconnected, promote mixed-use developments with a range of housing types, has a network of mass transportation and pedestrian-friendly designs, and is sustainable over time.

New urbanists see gated communities as enclaves that shut the city out. And therefore as anathema. While new urbanism advocates diversity and mixing, gated communities’ projects promise homogeneity and separate residential uses behind aviel of privilege (Grant ,2003).

Peter Calthorpe, a new urbanist claims that gated communities are manifestations of the growing imbalance between public and private space in American cities and suburbs: The gated community is perhaps the most blatant and literal expression of the trend [toward increased private space and the disappearance of public space]. (Calthorpe, 1993). The key-differentiating element between New Urbanism and gated communitiy is the emphasis on public space. Residential interaction is promoted by having more venues for social contact. In other words, interaction enables people to build communities, to commit themselves to each other, and to “knit the social fabric” (Beem, 1999). Gary Pivo, an urban planning professor at the University of Arizona, argues that when people or entire communities turn inward, it forces people to lose a sense of responsibility to their city or region (Lang and Danielsen, 1997), which in the long run threatens American values of democracy, diversity, class, mobility, and racial integration (Low, 2001).

Amirican institute of architects (AIA) cited that gated communities as much as harmfull to liveability in the city. It developed 10 criteria for livable communities which is encorging the mixed use development, Three of the ten principles are as follows: First, encourage mixed-use developments: Integrating different land uses and varied building type create vibrant, pedestrian friendly and diverse communities. Second, use vary transportation options of walking, biking and using public transportation, in addition to driving, reduces traffic congestion, protects the environment and encourages physical activity. Third, build vibrant public spaces to stimulate face-to-face interaction, collectively and mourn, encourage civic participation, admire public art, and gather for public events.

International making cityies livable (IMCL) conference established by suzanne crowhurst- lennard and henry linnard in 1985 in vinice to disscus ideas a bout livable places. This conference put Principle of (IMCL) for liveability are found in concept of traditional urbans, with particular reference and emphasis on the city as aholistic social entity, that requires a network of phyical meeting groups to encourge people to communicate, learn from each other, and enjoy the public life of the city. Sustainable design strives for compact development, environmental protection, citizen participation, equal access to services, concern for all members of the community, public spaces to bring people together, and architecture and zoning that promotes a sense of place.

All these trends streeses new development, First: to include mix of uses, to create a livable urban city. Second: encourage Social Interaction by including mix of housing levels, Pedestrian circulation, Traffic calming, Sheltered space for public interaction. Third: encourge variable alternative transportation options, to reduce car dependency and increase urban livability and sustainability. Fourth: increase public urban space, that increase urban, functional, social, political connectivity. Through this analytical comparative study,

between theory of good city form and practice of gated city form, its clear that, Gated communities stand short when measured to these good city form principles. On the conturary, gated communities is single use, eliminate public life from the city, dicourge transportation altarnatives, depend completely on motor car for every day needs, do no encourage civic participation, are not accessible, and fail to be diverse. so it is harmful to urban livability, connectivity, sustainability of our cities.

Key Echoes on the Relation between Micro Macro Relationships:

Through historical and theoretical analysis of micro-macro relationship. Gated community's highlighted many debatable echoes between internal urban pattern and external urban fabric, on social, economic, urban and functional levels:

- Debate on Sense of community, gated communities stressed the micro sense of community on the expenses of sense of being part of bigger community of the city.
- Debate on Safety security, gated communities stressed the micro internal safety on the expense of safety of the bigger community of the city.
- Debate on urban sustainability, gated communities strives for internal sustainability on the coast of external overall sustainability.
- Debate on Urban liveability, gated communities increased internal urban liveability on the expense of macro city liveability which transformed into merely continuous set of walls, have no life.
- Debate on Functionality, gated communities converted the city into a large number of clubs that are restricted to its residents, no public access to services or urban space. And which accumulatively affect the overall functionality of the city.
- Debate on Social relations, gates stress social cohesion on the cost of large social division.
- Debate between internal accessibility and external permeability on the coast of external division.
- Debate between internal multi-activity and external no activity.

7 LOCAL CONTEXT

Egypt has transformed its economy to a free market economy (Bayoumi 2009). the government followed laissez-faire policy (Bayoumi 2009) where the private companies put forward their design principles and ploy governmental regulations. The government sold large portions of public desert land to real estate developers to finance housing development(Khalil 2007), leaving the arena of developing these towns in the hands of private developers (Bayoumi 2009; Stewart 1996; Stewart et al. 2004). The new satellite cities around Greater Cairo, therefore, are now home to a growing number of resorts, golf courses, theme parks and amusement parks that offer tremendous entertainment facilities (Saoud 2002). The construction of privately planned gated communities has become a mass trend in new town urban developments on the outskirts of the Greater Cairo Region since the mid 1990s. They contribute to reshape the suburban landscape of GCR's new towns (Meyer 2000). Figure (8) shows the magnitude of this flourishing phenomenon(Yosry 2009).

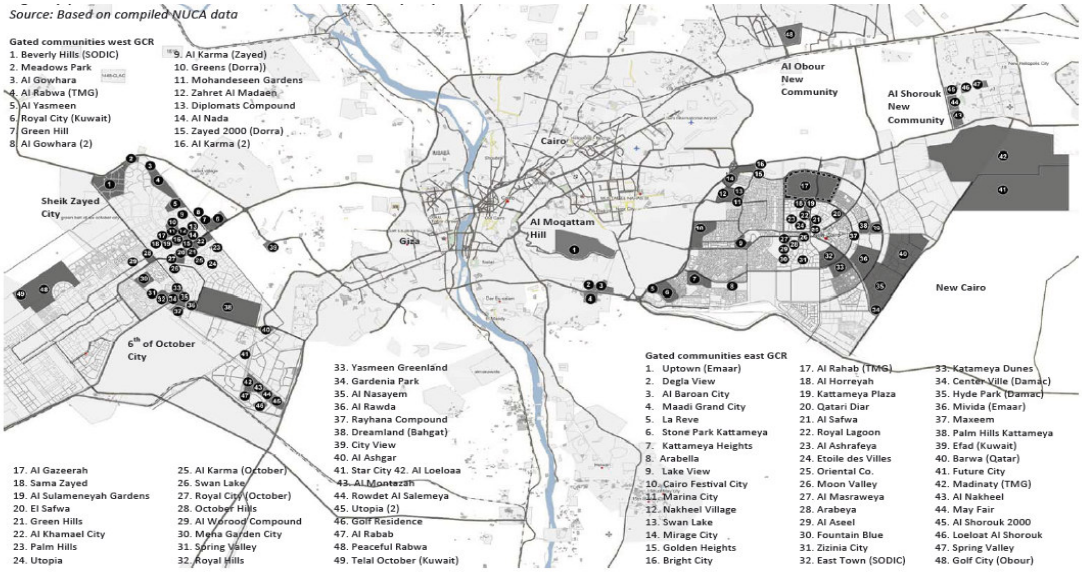


Fig. 8:Gated communities flourishing in GCR, source(yosry 2009)

7.1 Tracing gated developmental on plans of New Cairo city and impacts of urban livability

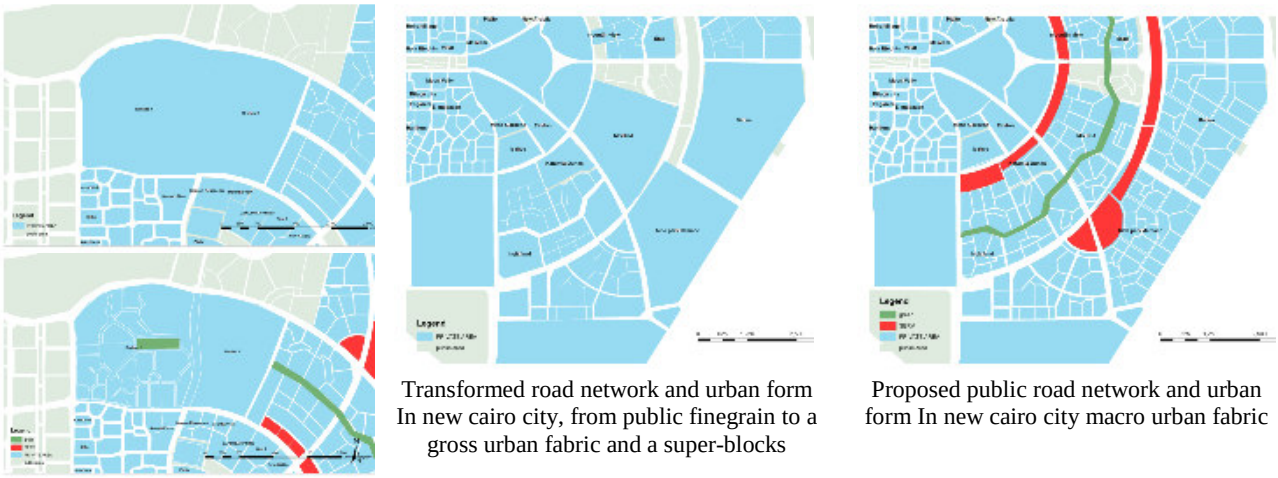
New Cairo city one of GCR new towns, has developed accumulatively on inconsistency manner in five different sequential master plans at 1985, 1995, 1999, 2001 and 2007, respectively (wael fahmy2009). last stages, reflected market driven forces, and flurishing of gated privatized areas. Planning polices and master plans, leading to dividing urban form and massive trend to enclosing large areas of land inside the city creating city of walls. This has bad effects on the liveability of the city. Isolating public streets from its life, and converting it to merely some zones and walls, that motor paths have penetrated it. Which draws a Frustrating picture for society Caged inside the walls, its parts has been divided from each other and away from the overall image of the city.

Fig. (6): Contemporary image of New Cairo city, (city of wall).

7.2 Planning response

A local authoritization trend shaowed some kind of un awareness of this effects on the city, the municipalitie, did not have a specific policy in dealing with this phenomena, especially land subdivition and

master plan approval. It didn't have a development control to control these phenomena for the sack of total development. It showed the lack of awareness of physical pattern and its consequences on the city.



Transformed road network and urban form In new cairo city, from public finegrain to a gross urban fabric and a super-blocks

Proposed public road network and urban form In new cairo city macro urban fabric

Fig 10: Transformed urban fabric in micro internal scale

many transformations have been done without coution to its effects, the government obayed developers pressure allowing him to make changes in urban fabric, changing its urban form and structure, for example el rehab 1&2 have been combined and gated area increased, also many projects like barwam mividia and hyde park increasing what is proposed in previous developed master plans. This change transformed urban fabric of new cairo city from public road network to a structure of super-block. Government have big role in the developing of this phenomena, rather than encouraging the new development to be part of the overall image of the society it increases fragmentation, and hence affect the public life in the city.

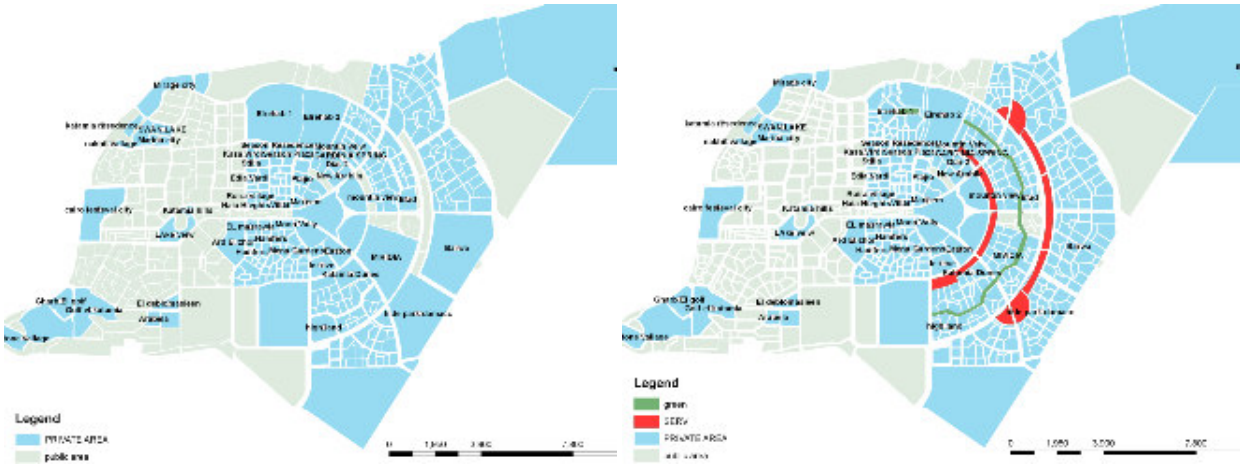


Fig 11: Authorities didnot has any strict strategy to deal with this development pattern, Transformed urban fabric in macro internal scale (from connected city to divided city)

CONCLUSION

Gated community generally and especially in Egypt, witnessed a great division between theory and practice, this division existed in the relation between gated communities and the overall city. Practicing Gated communities witnessed a second division, stressing the micro needs on the expense of greater macro effects on the overall city.

Throgh This study it is apparent that gated communities is not a holistic approach to community growth and can elminate public life, sustainability, integrity, continuity patterns of development. There is a need to reconnect the city for the good of connected, livable, sustainable city for every one. There is a need to find the connection between theory of good city form and practice of gated city form.

Practice of gated communitites	**Theory of good communities**
concern for ellite members of the community	concern for all members of the community
Single separate use development	strives for compact mixed development
lack transportation options (only private car)	Strives for alternative transportation options
Unconnected un permiable urban life	Connected permiable urban life
Walls and fences	Environmental protection
Do not encourage civic participation	Citizen participation
Not accessible	Equal access to services
Post public spaces elminated the public life	public spaces to bring people together
Just walls that shape public urban life	Architecture and zoning promotes a sense of place

City liveability against gated communities is one of the most important goals a state can seek. There is no single strategy to achieve this result. Rather, an interlocking set of initiatives in areas such as integration, accessibility, mixed land uses; environmental quality, diverse housing types, and boundary urban design can help promote livable internal external communities. Meeting livability needs will require the state's governmental jurisdictions, political leaders and businesses to move beyond individualism and self-interest to seek common goals and take collective action.

Albania in Transition: International Assistance for Roads but not Public Transport

Dorina Pojani

(Dorina Pojani, Polytechnic University of Tirana, F.I.N., Rr. M. Gjollesha, 54, Tirana, Albania, Email: dorinapojani@hotmail.com)

1 ABSTRACT

It is well known that international financing of enormous road projects in developing countries, justified primarily on "economic" grounds, has fueled the rapid growth in private automobile use with grave environmental consequences. During the transition to a market economy after the fall of communism, Albania has been the recipient of substantial amounts of foreign assistance in the transport sector, which has taken two forms in the capital, Tirana: (1) Technical assistance and funding for the preparation of numerous urban transportation plans and studies, mostly by foreign consultants (2) Financial aid for the implementation of various road infrastructure projects but not for public transport. This paper reviews the outcomes of this assistance.

2 INTRODUCTION

It is well known that international financing of enormous road projects in developing countries, justified primarily on "economic" grounds, has fueled the rapid growth in private automobile use with grave environmental consequences (see Hook 1994; Gutner 2002). While the World Bank's (2007) self-evaluation of the assistance to the transport sector during 1995-2005 concluded that past performance has been effective especially for intercity highway construction and rehabilitation, it also concluded that in the future transport lending must focus on issues such as traffic congestion, environmental damages, safety, efficiency, and affordability.

In the case of Albania, during communism (1944-1990) private car ownership was forbidden and public transport was poor. As of 1990, Tirana, Albania's capital, was a very compact and flat city with a population of 300,000. Its streets were virtually free of motorized vehicles and most travel was on foot and by bicycle. Buses, which were the only form of public urban transport, were used for voyages that would have required more than one half hour of walking. There were no intercity highways and travel around the country was very slow.

Since 1990, Tirana experienced a population explosion to well over 800,000, owing to rural-urban migration, and now contains almost one third of Albania's population. In this process, a dual city was formed, with the inner city becoming much denser and taller and the peripheries expanding in all directions with squatter settlements, almost entirely devoid of infrastructure. In addition, big box retail and light industrial sprawl emerged along the main intercity roads. During this period, car ownership skyrocketed. Now approximately two thirds of the households in the inner city own a car, but substantial portion of households that own cars limit their use to recreational travel on weekends. Tirana has been transformed into a city choked with automobile traffic and pollution and treacherous pedestrian conditions. Bicycle use has been reduced to a minuscule level and is perilous. However, most daily travel is still on foot and the main mode of motorized travel is still by bus (Figure 1 and 2).

Fig. 1: Traffic jams in Tirana's central area.

Fig. 2: Buses stuck in traffic in Tirana.

During the transition, Albania has been the recipient of substantial amounts of foreign assistance in the transport sector, which has taken two forms in Tirana: (1) Technical assistance and funding for the preparation of numerous urban transportation plans and studies, mostly by foreign consultants (2) Financial aid for the implementation of various road infrastructure projects but not for public transport.

Most donors' funds in the 1990s were allocated for intercity infrastructure because the national road network was in worse conditions than the urban road network (World Bank 2004). One consulting team reported that up to that time investments in urban road infrastructure had corresponded to the typical level of low-income countries in Southeast Asia and sub-Saharan Africa (PADCO 2002). Meanwhile, government operational subsidies to the public bus company ranged from $500,000 to more than $1 million per year representing 30-50% of its income (TECNIC and Transurb 2000).

Since 2000, the local government income in Tirana has increased considerably. In addition, large earmarked grants and credits were received from foreign donors. As a result, substantial urban improvement projects have taken place in the last decade. However, the bulk of transport investments has been for roads. At the same time public bus lines in Tirana (with one exception) were privatized (by Albanian companies) and subsidies for public transport are now limited $200,000 year for the one remaining publicly-owned line. Overall, the locally-based subsidies for public transport have been tiny relative to the substantial international funds, which have been allocated for road infrastructure (see Table 1 and Chart 1).

	Allocated Funds Yearly Average (1996-2000)*
Sidewalk repairs	$13,818
Traffic signs and signals	$314,000 (1998)** $23,000 (2000)
Road maintenance/repair	$1,089,682 (average) $71,800 - $2,075,000 (range)
Public works total (including road and sidewalk repairs and traffic signs and signals)	$5,320,000
Public transport	$760,000
Other (including trade, culture, administration, public health, education)	$12,920,600
Total average yearly budget 1996-2000	$19,000,000

*100 Lek ~ 65 US cents (2000 exchange rate)

** Including the establishment of a traffic signals enterprise

3 FOREIGN TECHNICAL ASSISTANCE AND FUNDING FOR PLANS AND STUDIES

Since the beginning of the transition, foreign donors have funded no less than ten urban transport plans and studies for Tirana, prepared mainly by foreign consultants (in some cases invited by the City, in others hired directly by the donor organization). In most cases, the principal recommendation of these studies was to strengthen the public transport sector.

- In 1993-1995, a Brussels-based transportation planning firm, Transurb Consult (now Transurb Technirail), prepared a study on the reorganization of the public bus system in Tirana, funded by the European Commission PHARE program.
- In 1995, Regional Consulting, a Vienna-based urban planning firm funded by the Austrian government, prepared a master plan for Tirana, which contained a large transport element.
- In 1997-1999, the French transportation company CGEA (now part of Veolia Transport) funded by the European Commission PHARE program, led a technical assistance program in Tirana, which sought to help transfer institutional and financial authority for public transport from the central government to the City of Tirana.
- In 2000, T.E.C.N.I.C. Consulting Engineers, a Rome-based firm, and Transurb Consult prepared a large comprehensive transport study for Tirana (TUTIS), funded by the World Bank.
- In 2005, AlbanianTech Project (an Italian-Albanian cooperation) funded by the United Nations Development Program prepared an urban development strategy, which included a number of transport recommendations for Tirana.
- In 2006, Peter Guest, a British parking consultant, prepared a detailed parking study for Tirana.
- In 2007, an Albanian urban planning non-profit organization, CoPlan, carried out a comprehensive study of public transportation services in the Tirana metropolitan area, funded by the SOROS foundation.
- In 2007, the European Commission and FIAB, an association of bicyclists in Bari, Italy, provided 166,700 Euro for a one year training program in transportation planning for the City of Tirana staff, in the framework of the MO.S.T. Programme for sustainable mobility
- In 2008, the Albanian chapter of an international non-profit environmental organization, the Environmental Center for Administration and Technology (ECAT) in collaboration with a German consultant (Rainer Graichen), prepared a new “sustainable urban transportation study”, funded by the EU LIFE program, the German Ministry of the Environment, and the European Bank for Reconstruction and Development (almost 300,000 Euro).
- In 2008, in the framework of the New Neighbohood Programme Italy-Albania Interreg/Cards 2004-2006, the Transportation department of the Polytechnic University of Bari in Italy, in collaboration with several Albanian partners, prepared a study on the future sustainable planning of urban transport in Tirana, focusing on the optimal positioning of an intercity bus station.
- The World Bank and the Dutch government offered $1.7 million (credit) and $1.5 million (grant) respectively for the preparation of the Tirana Regulatory Plan, which is currently (early 2010) awaiting approval. The regulatory plan was prepared by a Swiss company, Urbaplan, and CoPlan.
- This year (2010) the City of Tirana will release for public review a new “Masterplan for Sustainable Urban Transport Development” that, in the next twenty years would create 100 km of new segregtated public transport lanes, including about 20 km of at-grade tram lanes, as well as introduce many innovative traffic management devices. The details on costs, consultants, and funding sources have not been made public yet.

These studies contained detailed recommendations. Some of earlier studies focused on the reduction of government subsidies in the public transport sector, through the gradual introduction of competitive mechanisms and, eventually, full privatization, with the City acting as a monitoring authority. Consultants also provided assistance in drafting contracts between the City and private operators and standardizing financial and audit procedures. Other regulatory and institutional reforms in the public bus sector were also proposed, including the creation of local and/or regional bus transport associations or agencies in charge of service coordination and the increase and/or liberalization of public transport fares. Several studies proposed

the introduction of pricing mechanisms in urban transport, such as the application of parking charges in main streets and in residential neighborhoods. The 2006 study by Peter Guest, in particular, provided detailed guidelines in this respect, based on the example of other European countries.

In addition, the studies also made many recommendations for physical interventions, with the purpose of supporting public transport and non-motorized modes, the principal of which was the creation of exclusive bus lanes, starting with heavily used corridors such as the Ring Road and the main Boulevard and creation of exclusive pedestrian areas in the center. The 2008 sustainable urban transportation study, in particular, was a strong proponent of the creation of a Bus Rapid Transit system in Tirana (25.3 km at first and another 12.2 km in a later stage, with an estimated total cost of 97 million Euro). A few studies mentioned the introduction of light-rail in the main urban corridors and in corridors leading to the newly formed suburbs.

These plans and studies provided valuable recommendations on sustainable transport development, consistent with international concepts. However, in large part the studies mainly reiterated what had been set forth in earlier studies and most of them were not implemented (Punavija 2008). In most cases, funding was secured only to prepare the studies, with no provisions for implementation.

Some studies focused on road improvements, TUTIS in particular (which estimated that $60 million were necessary for road upgrades), including recommendations such as: construction of a small ring road around the center (which would allow the center to be pedestrianized) and construction of a third ring road, which would serve as a by-pass for heavy-traffic.

Unfortunately, studies and plans were not widely circulated and most were not even translated into Albanian. Commonly, current public administration employees are unaware of their existence. Despite recent freedom of information laws in Albania, the study reports are not easily obtained and commonly treated as confidential and often cannot even be found (epic efforts were required in procuring some of the studies).

The reasons for the failure to implement these plans were multiple. Several consulting firms noted in their reports a number of challenges that they feared would undermine successful plan implementation. The principal problem was that the City simply did not have the resources to carry out these plans. Other problems included: excessive centralization and scattered institutional responsibilities among public sector agencies responsible for urban transport; lack of motivation of the Albanian staff due to low wages; low levels of concern about environmental issues; lack of staff trained in transportation planning; and an inadequate legislative framework (Regional Consulting 1995; CGEA 1999; T.E.C.N.I.C. and Transurb 2000; Peter Guest 2006; ITS 2006).

4 FOREIGN FINANCIAL ASSISTANCE FOR PROJECT IMPLEMENTATION IN TIRANA

The three main foreign donors in Albania have been the World Bank, the European Bank for Reconstruction and Development (EBRD) and the European Investment Bank (EIB).

Albania joined the World Bank in 1991. World Bank's total commitments to the country to date (for all types of projects, not just transportation) total approximately $925 million. Support for the capital's transport sector has included the following:

- In 1993, the World Bank initiated a countrywide "Transport and Infrastructure Project", which was meant to (a) assist the Ministry of Transport and Communications and transport organizations to adopt market based transport policies; (b) accommodate the expected growth of road traffic by rehabilitating and completing/extending main roads and by improving their maintenance and safety. By 1999, $18.5 million had been disbursed. The Tirana component of this project included assistance in road maintenance through the provision of equipment.
- In 1998, the World Bank committed $15.86 million (credit) for an "Urban Land Management Project", to provide essential urban infrastructure (including roads and other infrastructure and services, but not public transport) to underserviced or neglected areas in Greater Tirana and to strengthen the institutions responsible for the delivery of urban services at the national and local levels.
- In 2002, the World Bank approved a $30 million loan for a country-wide "Road Maintenance Project". By 2005, $18.7 million had already been disbursed, with the Tirana urban roads component absorbing $1.83 million.

- In 2005, the World Bank approved a $20 million loan for a countrywide "Transport Project". The Tirana component of this project included the rehabilitation of 3.5 km stretch of the Middle Ring Road and a pilot traffic management program, which provided for improvements in signs and signals, intersections, pedestrian crossings, and road pavement.
- In 2008, World Bank approved a $20 million loan for a "Secondary and Local Roads Project" which targeted mainly rural areas, but also provided some funds for urban roads (1,000 – 1,500 km of roads in total). The project was also meant to support the introduction of the private sector in road maintenance on the road network.

The European Investment Bank (EIB) has financed various sectors in Albania since 1995; its investments have reached 304 million Euro in total; of these, 138 million have been for national roads construction and upgrading. The only program that will benefit the Tirana transport sector is a national "Secondary and Local Roads Program", for which EIB is offering 50 million Euro in total. As of 2009, the program is still under appraisal.

The European Bank for Reconstruction and Development has been very active in Albania's transport sector as well. Its investments that affect Tirana's transport sector include:

- In 2006, in the framework of the "Tirana Municipal Transport Project", the EBRD approved a €14.6 million loan for the widening and upgrading of various Middle Ring Road stretches (3.5 km), the rehabilitation and development of other priority components of Tirana's municipal roads, and the construction of an interchange on the intercity highway. By 2008, EBRD had already provided 4.5 million Euro for the Middle Ring Road upgrades.
- In 2007, the EBRD provided a 500,000 Euro credit for the creation of a computerized traffic management center.
- In 2009, the EBRD provided a 24 million Euro loan and a 400,000 Euro grant for the construction of a 5.75 km section of the Outer Ring Road stretch (which will cost 40 million Euro in total) and an overpass at a city exit point.
- As of 2009, the EBRD is considering providing a 24.0 million Euro long term debt facility for the construction of a shopping mall in the outskirts of Tirana, with a gross leasable area of 39,000 m2. The project is part of a general plan to develop a chain of shopping and entertainment centers across Albania, following the development of another suburban mall in 2005 (Qendra Tregtare Universitare). The project will be required to comply with national and EU environmental, health and safety standards and requirements.

5 CONCLUSION

The substantial international support for travel within Tirana has largely bypassed the needs associated with the vast majority of travel within the City. Foreign funds for Tirana's transport sector were provided for road construction and improvements rather than public transport, notwithstanding the fact that all the internationally funded studies highlighted the need for assistance in this sector.[1]

The reasons for this disparity within the same constituency have not been publicly stated. However, several factors emerge as likely factors. International organizations and governments prefer to fund one-time projects with discrete visible outcomes, meaning roads, rather than improving ongoing operations, such as bus systems. On the national level, elites have more concern about improving the conditions for car travel, than public transport.

However, some of the international financial institutions that are active in Tirana have provided public transport financing for other East European cities, which were perhaps more active in requesting funds for this purpose.[2] In Albania, on the other hand, despite the democratic forms of government since 1990, the

[1] Foreign funds have mostly been loans rather than grants, which make Albania dependent on outside providers through debt repayment for lengthy periods. In addition, a large share of the funds has found its way back to the donor community through expert fees for planning.

[2] For example, for EBRD's public transport financing in East Europe see the following EBDR web pages:
Lviv, Ukraine http://www.ebrd.com/projects/psd/psd2009/39299.htm (up to 38 million Euro for the public transport company, currently under evaluation)

absence of longer political traditions or precedents for popular representation still hinders the effective conversion of public desires into public policy. A general distrust of government institutions of all levels still persists and there is no public belief in any possibility of successfully pushing for change (Pojani 2010). Therefore, the reasons why transport problems have not been tackled at a sufficient level are mainly political rather than technical and financial.

Naturally, an adequate road infrastructure is an important component of a good public bus system. Many necessary road repairs, upgrades, and construction in Tirana would not have been possible without foreign financial help. However, the public transport system also deserves its share of attention and funds considering its poor condition in comparison to other European countries and its importance and high usage in Tirana. A relatively small portion of the overall international funding for transport may have had a major impact on the adequacy of public transport, preservation of the ability to travel by bicycle, and the conditions for pedestrian traffic.

Tirana is in a very favorable position in the sense that its transport problems and adverse transport externalities may be substantially alleviated without exceptional public investments due to the high density, moderate population size, and flat terrain of the city. As a result, much urban travel could be conducted on foot, by bicycle, or with short bus rides. Strategies with a high impact but moderate cost are set forth below:

1) Making street conditions friendly to pedestrians,

2) Pedestrian only zones in central areas,

3) Traffic calming in residential neighborhoods,

4) Exclusive lanes for busses and bicycles, which are adequately protected from car traffic,

5) Reasonable parking fees,

6) Scrap programs for old, polluting vehicles,

7) Adequate taxation to encourage the use of “clean” vehicle technologies.

Investments in public transportation should focus on improving the bus system (rather than introducing high cost rail systems). A second step would be the creation of Bus Rapid Transit (BRT) system. These are financially realistic and environmentally sustainable strategies. The Albanian public sector must play an active role in requesting funds for these specific purposes rather than be conditioned by the requirements and ideologies of donor organizations.

An Operational Model towards Playful Public Participation

Viviana Lanza, Lucia Tilio

(PhD Student Viviana Lanza, University of Basilicata, viviana.lanza@unibas.it)
(PhD Student Lucia Tilio, University of Basilicata, lucia.tilio@unibas.it)

1 ABSTRACT

After a brief review of e-participation potentials, principles and practices, this paper develops an operational framework for the conduct of playful public participation experiences. The operational model captures the key elements of traditional planning processes, but uses technological-driven decision making tools techniques as well as a "playful" approach designed to capture the motivations of both public administrators and the participating public. The playful participation model is parameterized using both SWOT analysis and a Logical Framework Approach. The last part of the paper illustrates the operational model in a case study conducted in a South Italy city, Potenza, over the past 7 months, concerning planning of public spaces for young people.

2 INTRODUCTION

Participation process arises from the necessity to break down cultural barrier both for administrators, like subjects placed before, in an institutional way, take a decision, and for subjects involved in participation process.

The administrators show mistrust of participation process because they are afraid that it could be cause of conflicts and because they generally do not want renounce to be the privileged decision supporters, retaining that their choice is the best decision, in fear it could be modified by participation process.

For subjects involved in participation process, instead, it has been noticed an insufficient and unrelevant use of active participation, that it can be translated into a general mistrust, caused by lack of participation culture.

In order that participation could be effective, it is necessary a cultural change both from administrators and from subjects involved in participation process; this change implicates ability and will to work in team, to make roles transparent and to share information in efficient way, but above all to debate and think back to own opinions and chooses.

To build this change it is important consider several aspects: in particular, what kind of tools to use, where to "participate", how to participate.

Concerning tools, it has been noticed that decision making tools, and in particolar technological ones, are effective to create a common knowledge base and to organize and manage the process, making it transparent and making possible to repeat in the time. In a reality like this, they can definitely help in order to manage communication and participation, even if they cannot - and they must not - replace contacts and relationships that can be created among people demanding direct connections and costant dialogue in the time.

Concerning where to participate, it is important to choose right place: comfortable environments where people can talk and have a confrontation; where it is possible to organize meetings, with different kind of people, making everyone at oneself ease; it is important organize special events in place where people live, finding local speakers; above all, it needs to do coherence to all these meetings, succeeding in making a coherent project, by different kind of input.

Sharing moments have to take into account, preferring an informal approach, based on the concrete representation and exemplification, in order to illustrate concepts and themes concerning the discussion; during these moments, it should take into account also maps and plastic models, and all kinds of communication that do not need complex texts reading.

Finally, in many cases, it is useful a ludic approach, that for instance takes into account moments for voting different alternatives through coloured coupons, or it considers simple simulation tools able to show "what happens if…".

In light of these remarks, Playful Public Participation seems to find rich soil; it seems to be the most suitable approach to make close subjects involved in planning participation process. Even if Playful Participation is a good method to participate, and even if it could be effective in order to break down the mistrust barrier, with this paper we affirm that it is not enough in order to guarantee the effectiveness of participation process

itself; we propose therefore a new way to make planning and to make participation, a way that could join the rational planning approach, starting from context knowledge frame, to problems and objectives identification, and intervention policies predisposition, arriving to define intervention strategies, showing future and possible scenarios, with the Playful Public Participation approach.

The paper is organized in three sections: the first section starts with a brief review of partecipation and e-participation concepts, where we discuss about the new era of participation process; this section continues debating on a renovated approach in rational planning, introducing two methodological tools able to identify problems and objectives, to predispose intervention policies and to define intervention strategies, showing future and possible scenarios. The second section is the main section, because it's just in such part that we propose the new way to make planning and to make participation, a way that joins the traditional approach with playful approach, in the convinction that this "wedding" brings subjects involved in participation process near to planning. The third part of paper illustrates a case study, conducted in a South Italy city, Potenza, over the past 7 months, concerning planning of public spaces for young people. In the end we presents results, as a discussion focused on the integration between traditional and innovative way to make participation, through the reading of case study results.

3 PARTICIPATION PROCESS IN WEB 2.0

The increase of importance of communicative aspects in urban planning has been led the participation, and moreover the e-participation, to hold a role more and more decisive in planning process (Hajer, 2001). In the "Information Society", Public Administrations use new technologies more and more often, with the purpose of establishing a rapid, direct and transparent relation with citizens…or, at least, they are trying to do it! The Information and Communication Technologies (ICT), therefore, play a fundamental role into building consensus in democratic processes, giving more relevance to citizens in need to be involved in decisional process (Tambouris, et al, 2007).

All around the world, e-participation projects are on-going increasing, and many Administrations are actively engaging in the use of new technologies in order to involve citizens in democratic processes; although this positive tendency, public participation quality is still making better.

Citizens involvement in policies is not easy as it seems to be. First of all, an effective participation has to be based on correct information that poin out rebounds on territory by scenarios building, able to simulate different choices.

The use of new technologies in urban planning processes, with the aim of improving communication quality and widening interation between all stakeholders, could, without doubt, enhance use of bottom-up approach (Knapp and Coors, 2008). It tries to stimulate less involved part in the process in acting and partecipating, with collaborative behavior. Citizens, who feel involved in planning process development, as shown in Tilio et al. (2009), feel that their initiatives could be appreciated and approved; various alternative solutions, elaborated thanks to practical sense that tipically characterizes city user, could be identified from every citizen.

Now then so, participation process successful is attributable to citizens involvement in policies. Since 1969, when Arnstein developed his theory about Citizen Participation, it was introduced public involvement concept, as a way to redistribute decision-making power and as a key to determine whether public involvement is meaningful.

If participation process is devised and if citizen takes part in participation process, then there will be benefits for entire community.

In a participation process it is necessary to involve people at a very early stage, so as to create a dialogue between them. And just this dialogue allows participants to reach a consensus on something. Moreover citizens can identificate themselves with the project, because they have taken part in working it out. This can improve the preparation and realization of the measures (Krek, 2009).

Participation is something of objectively good for all community; mentioning Arnstein (1969) thinking, "The idea of citizen participation is a little like eating spinach: no one is against it in principle because it is good for you!". Or else, following Krek (2005) thinking, the word participation in general means something

positive; it implies that someone is cooperating, "playing" along with the group or an individual, working with others in order to achieve a common goal.

In a pilote study led by Conroy and Gordon (2004) it has been verified an higher popularity level in a meeting where participants used advanced technolocigal tools, as GIS-based ones, compared to traditional public meetings. The measure in which information is really perceived from citizens and, thereby, the possible participation rank could be due to way in which information is presented (Simmons, 1987). A participation environment, where it uses internet technology like a tool to involve public part, is, as a consequence, an environment that facilitates knowledge and information storage; visual systems as maps and imagines are mainly recognized from participation processs members (Conroy and Evans-Cowley, 2006). The studies led by Conroy and Gordon (2004) demonstrate how e-government tools go on a promise to improve public participation opportunities; with passing of years and, consequently, with improvement and diffusion of technologies, that promise becomes more and more achievable. Like observed by Thomas and Streib (2003), citizens visit more and more websites, perceived as the principal mean to collect information and interact with Public Administration. According to Rodotà (2007), "Internet is the biggest public space that humanity has known a place where all people can express themselves, gain knowledge, get ideas and not only information, deny, dialogue, partecipate to common life and so, build a different world where everyone could feel equally citizens".

Nowadays, infact, online social networks or communities have created a multitude of virtual spaces on which people can socialize (Facebook), share content (Flickr, YouTube) and expertise (Wikipedia). Through this virtual space it is possible exchange digital information and facilitate social interactions between users and organize different types of groups (Apostol, 2008).

More in general, Internet and World Wide Web are generating radical changes in the way we are able to communicate. Our ability to engage communities and individuals in designing their environment is also beginning to change as new digital media provide ways in which individuals and groups can interact with planners and politicians in exploring their future (Hudson-Smith et al, 2002). While citizens are becoming e-citizens (Prosperi, 2004), government must enable citizens to increase participatory skills through Internet, contributing to growth of references to e-society, e-democracy and cyberdemocracy: we assisted, in yers, in "collective intelligence" (Lévy, 2002).

Public participation based on online communication is become, in the last ten years, a real research field, and the innovative impulse in web-based application field, due to ICT, lead to new form of communication among citizens, planners and public authority. New generation tools are a lot and, if used opportunely, could lead to a good level of effectiveness; we can think to chatrooms, forum online, web surveys, workshops and virtual conferences, e-mails and discussion exchanges through online maps. An integration of geographic information systems (GIS) and public participatory tools represents one of the latest innovations in this area (Krek, 2008).

Therefore, the new technologies and the new way to partecipate to planning choices feel the effects of deep change, innovate themselves, get rich in contents and experiences and evolve towards the new era of the web 2.0, that seems to be attractive to promote participatory practices among citizens, because its tools are becoming more and more familiar to them, and just this familiarity could greatly increase potential participation (Lanza and Prosperi, 2009).

A concepts, proposed by research group of HafenCity University of Hamburg, that open the way to quality and effectiveness of participation process in urban planning is Playful Public Participation one. The key idea of Playful Public Participation (PPP) is to generate pleasure and joy for the citizens involved in public participatory processes, in particular for the interaction between citizens and planning experts. [1]

With Playful Participation it is possible use the game as a stimulating computer-based tool that can potentially involve citizens in serious public participatory processes (Krek, 2008).

Following Huzinga (1995), who asserted that one of the most significant (human and cultural) aspects of play is that it is fun, with playful participation, discussions and comparisons can be stimulated, offering to all stakeholders a tool for "play to build" intervention alternatives through combination of action proposals.

[1] See http://www.hcu-hamburg.de/geomatik/digitalcity/research-ppp.html, last access on February, 2010

In the playful public participation concept, the union among dialogue, comparison, design and fun is the secret and special ingredient to let really involve people in public participatory process.

4 TOOLS FOR A RATIONAL APPROACH IN PLANNING

Until now we have exposed teorie about ICT tools, claiming how it is useful and fundamental a participation process in a decision making process and supporting Playful Public Participation principles. Well, we are convinced of this, we believe in this way to make participation. Nevertheless, our urban planning training impose to jump back into the past and retrieve some concepts that are at the early stages of a participation process: that concepts are connected to rational planning.

In the last decades, social processes have been changed, and interest in public decision sphere has been enhanced; "face-to-face interactions in the real time is the new model of planning" (Friedmann, 1993), and the new planning is transactive, that is it asks for interaction between two kind of knowledge, that one of experts and technicians subjects and that one tested. Tested knowledge, that planners have to make explicit, is citizens'knowledge, important because citizens live experiences, situations and contexts.

Decision in planning is developed in a process where knowledge about ambitions and objectives is growing and where stakeholders and "les agis" (Roy, 1985) influence directly or not directly the choice, considering the importance of objectives and alternatives for each one. To address decision toward an optimal solution, respecting public interest, and considering the three principles of planning, that are equity in choices, effectiveness and resources preservation, concept of plan rationality is central (Las Casas and Sansone, 2004).

Rationality in planning supports the planning process in all its phases with several techniques and methodological approaches; in our vision, the reference term is to consider plan as a decision process, and to adopt a procedural approach (Faludi, 1987), where knowledge grows in an incremental way, considering logical consequences and linking decision evaluation to the strict process itself.

4.1 The Logical Framework Approach and the SWOT analysis as methodological tools for public decision

Planning process is based on objectives and problems identification, strictly connected to the context kwnowledge: the preliminary analysis of context becomes a fundamental element of planning process, and the urban survey carries out a double role: if on one hand survey is the technical essential requirement for plan, on the other hand it can be considered a learning moment concerning town problems recognition and a tool to re-build history, tradition, culture, starting from which designing future development (Fera, 2008).

4.1.1 The SWOT analysis

Urban survey can be carried out adopting analytical procedure, as SWOT analysis, in order to detect spatial and/or social situations relevant in planning process, enabling participation to analysis process and helping in problems and objectives identifications.

SWOT Analysis is used in business administration since 50s, to support choices through a rational approach and a transparent decisional process, and it is common also in public administration since 80s, to build possible economic development scenarios. Today, according to European Commitment Regulations (Guijt and Woodhill, 2002), evaluation of plans and programs must consider a SWOT analysis.

The name is the acronym of the main components of the analysis itself: Strengths, Weakness, Opportunities and Threats are the evaluation dimensions. The identification of these components, in the better way, and possibly with a large involvement of actors, is preparatory to the definition of strategies and actions necessary for the accomplishment of defined objectives. In fact, the four components of SWOT allow to highlight the characteristics of the analysis'argument and to understand the internal mechanisms to modify, and at the same time they allow to take into account the external context, able to influence the fulfillment of objectives; strengths and weaknesses have to be interpreted as the endogenous variables, face to the external ones, represented by opportunities and threats. This distinction is important because it allows to identify the elements on which it is possible to intervent and the elements not directly controlled. The SWOT matrix, containing the identified components, is the results of a detailed context study, often based on quantitative data, but simply achievable in a participatory context, where involved subjects can discuss about evaluation

dimensions. Moreover, today it is usual to represent spatially the SWOT analysis, identifying on maps, with help of GIS, the evaluation dimensions themselves, obtaining maps with high communicative potential: we speak about "geo-SWOT ".

4.1.2 The Logical Framework Approach

Starting from SWOT output, decision process needs a hierarchical organization of problems, in order to define a structure where objectives, intended as problems removal, are connected to actions, attended results and spent resources. From this point of view, the Logical Framework Approach (LFA) represents a useful tool. It is commonly used as a tool for management of development plans and it was initially developed in the "management by objectives"; recently, European Commission adopted LFA to manage international cooperation interventions.

LFA supports the analysis and understanding of components of program and plans, highlighting the logical processes that join them. In particular it allows to consider in an integrate way the following elements:

- Project's objectives, distinguished in four levels: goals, purpose, output and input;
- Relations between cause and effect among the above mentioned levels;
- Analysis of external factors to justify the relations;
- Objectives verifiable indicators (OVI) and related tools to verify, manage and evaluate objectives' fulfilment (Gasper, 1999).

With this structured approach it is easy establish priorities and determine attended results from a projects, considering a logic series of phases:

1. Identification phase: existent conditions are analysed, project pertinence is investigated and objectives and strategies are identified; this is an analysis phase, during the which several kinds of analysis are carried out. In particular, a stakeholders analysis, in order to identify and characterize potential major stakeholders and to assess their capacities; a problem analysis, in order to determine cause and effect relationships for identified key problems; an objective analysis, in order to develop solutions from the identified problems, and with relevant importance to means and end relationships; finally, a strategy analysis, in order to identify different strategies to achieve solutions and select the most appropriate one.

2. Formulation phase: project is prepared, through declaration of clear objectives and measured results; this is a synthesis phase, characterised by three main activities; first one, logical framework matrix is developed, so that project structure is defined, and risks and its internal logic are tested, indicators are formulated; the activity scheduling determines the sequence and dependency of activities, and supplies information about their estimated duration and the assigned responsibility; to complete, the resource scheduling develops input schedules and a budget.

3. Implementation phase: negotiation, operative phases and monitoring are controlled;

4. Audit phase: decision making process can be opportunately synthesized, and objectives achievement can be evaluated.

The approach promotes stakeholders participation and so negotiation (Coleman, 1987).

5 HOW TO GET BETTER PLANNING PROCESS? "RATIONAL+PLAYFUL" APPROACH

Into strategic-rational planning processes, knowledge represents a fundamental condition to define plan actions; in this strategic-rational vision, it is considered as "experted" knowledge, exclusive planner'heritage. On the contrary, into the strategic participated model, knowledge is produced into an interaction process between several actors. Consequently, context analysis can be considered as a result of expert scientific knowledge and reality-made knowledge, tested by citizens. In a community planning process, collective experiences and technical analysis interchange and interact continuously, and in reason of nature of community planning process, that is addressed toward the action, analysis methodologies are structured so to supply useful information in order to identify objectives and strategies. (Fera, 2008).

Therefore, we can consider on one hand a methodological approach to context analysis and strategies definition, that we can call "rational approach", and on the other hand, a not formal approach to participation

in planning, that we can ca ll “playful approach”, borrowing the term that Hamburg HafenCity University group has coined.

Here, we want to compare these two methodologies, starting from the idea that their combination can give strenght and effectiveness to planning process, and, moreover, to the choices definition process. This is our convinction, this is our methodological proposal to tackle a participated planning process.

So, we are persuaded that the two different approaches, rational and playful, could become the new frontier into urban planning system: to analyze a urban context, identify one or several problems, define the objectives (like dual of problems) to reach, identify and carry out some strategic actions in order to solve identified problems. In all this process we think that citizen has a key role, because he could be fundamental in problems’definition (as a real user of the city and so of its problems), and at the same time fundamental to take a decision about strategic actions (as future real user of city and so of its benefits carried out from the identified actions).

Figure 1 makes explicit our proposal: in a simplified way, planning process is schematically presented in its two macro phases: context analysis phase, more formal and structured (via SWOT Analysis and Logical Framework Approach), and participation phase, free and less formal (via Playful Public Participation).

Fundamental phase in a community planning process, is starting phase, that asks care and deepenenig, in reason of its being preliminary to planning process. But the question is: when does planning process start? It starts when a social subject (public or private), on the basis of observations, problems, instances, considers convenient to develop a transformation process, and he becomes promoter of transformation initiative.

And what about participation and its role in this planning process framework?

It is necessary activate participation process since planning process starts, when planners think about scenarios and visions of future. Participation, in fact, can not be limitated to attuate already defined strategies: citizens have to be involved when strategic options start to be discussed. However, usually a great part of conflicts born during the transit from strategies to realization of strategies themselves, so that it is important that participation process is still alive in all process phases, also actuation and management ones.

In order that we can really talk about participation, so, it is fundamental that not all choices are yet done.

Public participation is an important part of urban development. If people are being integrated into planning process, the planner is able to see through different perspectives and gets to know new ideas and opinions, thus conflicts can be solved more efficiently. Furthermore citizens acceptance towards new developments and ideas increases (Krek, 2009).

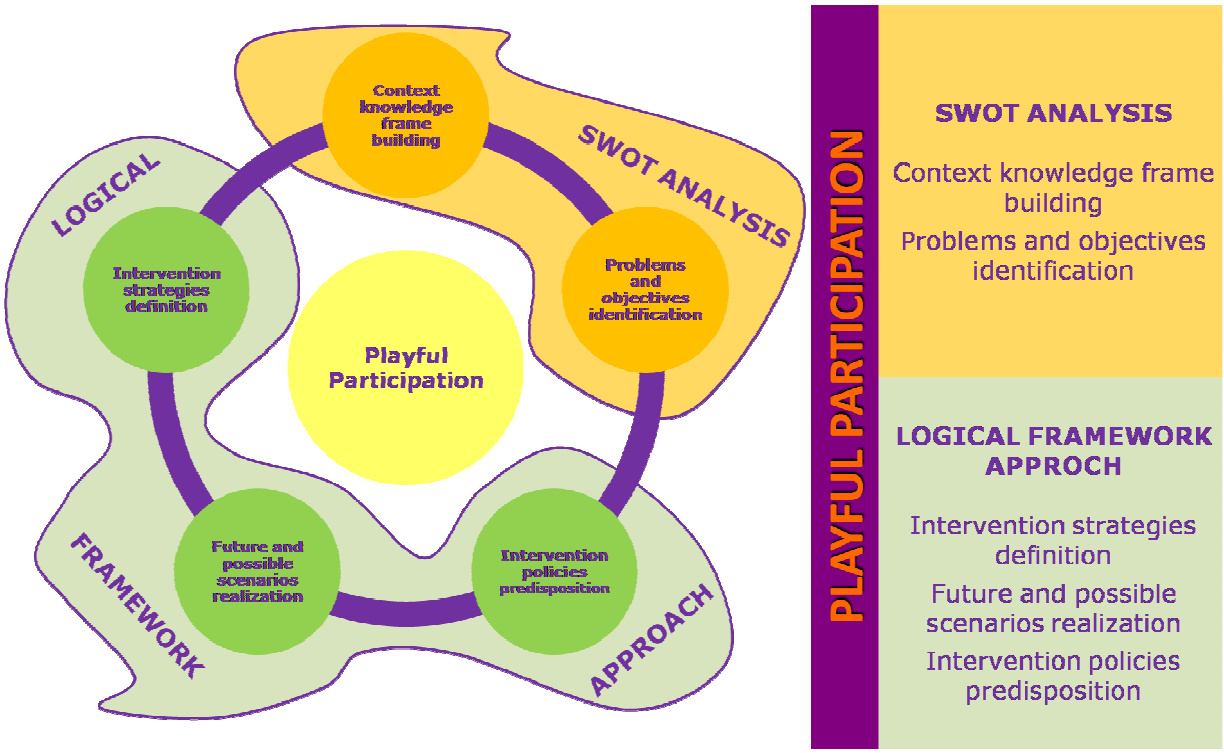

Fig. 1: Scheme for a "Rational+Playful" approach

Our thesis is to not consider the participation process as ex ante or ex post process, but as an on-going process, that must go with all the planning process; we intend planning process considering the traditional phases (context knowledge frame building, problems and objectives identification, intervention policies predisposition, future and possible scenarios realization, intervention strategies definition) as essential, but inserting in the core of the process playful participation, embracing all the phases; moreover, we would include in the process the use of traditional but always current methodologies, SWOT Analysis and Logical Framework Approach, as the way to introduce and guarantee rationality of process.

5.1 Case study: planning public spaces for young citizens

In this paragraph we describe an interesting study case concerning planning of public spaces for young people in a little town in South of Italy, Potenza. Research started from the detection of not coincidence between request and supply, in terms of spaces, from and for young people: relating to the presence of some public spaces for young people, not really used, and at the same time the discontent of young, not satisfied of life in the town, researchers rhetorically ask if there is a problem in planning so that results are not effective. In order to answer to the question, and, more important, in order to define a methodology to carry out a rational and effective planning in the context of young citizens needs, researchers have involved young people and several operators in the context of young policies into a simulated planning process.

Involvement required definition of several interaction forms; starting from light interactions forms, suitable in particular in brief and not strongly structured participation process (Fera, 2008), researchers planned a set of surveys, the creation of a focus-group, with the organization of several meetings, and the support, for all these activities, of social networking website.

Choosed social network has been Facebook. If in general this kind of virtual communities allows people to connect and interact with each other (Murray and Waller, 2007), Facebook has been considered the most suitable in reason of its spread diffusion, its daily consultation from main part of users and its nature of multi-sharing-functions (i.e. possibility to share moods, links, photos, events and so on). Researchers have created a facebook group, where they posted all information about the planning process, they communicated events, they published photos and videos registered during the events, and thanks to the pervasiveness of social network itself they succeeded to obtain a number of members on about 800 people, that is not negligible dimension in the study case context. According to Chiu et al. (2008), participation in online social

networks becomes a new communication and interaction phenomenon, so, Internet has been used as a communication tool in a group decision-making process (Hanzl, 2007).

Through the Facebook group, members have been invited to answer to an on-line survey, powered by Google-docs. Survey'aim was to better define the detected problem, considering the opinions of young people, divided into three different groups, in relation to their age. Concerning their needs, their customs and their capacity to express opinions, young people, considered from 15 to 35 years old, has been divided into three groups: 15-19 years old, 20-24 years old, 25-35 years old. Survey answers, presented during focus group meetings, helped into context analysis, in particular they have been the basis for the SWOT analysis.

Fig. 2: Activities for light interaction forms: focus grouop meetings, web-survey, Facebook group

During focus group meetings, SWOT analysis has been lead, highlighting the main aspects of problem and identifying the main instances to evaluate in planning process. Participants played to relate elements on their territory, and after a review of problems with the help of a bulletin board and a big number of post-it (of different colours, one for each element of SWOT), they used google Maps to localize. Relating the identified elements to tackle, avoid, exploit and transform (that is, the strengths, the weaknesses, the opportunities and the threats of a SWOT analysis) to concrete objects on territory, and building maps give more emphasis to the analysis, and make more effective the involvement of actors, thanks to the power of visual component into the process (see Figure 3).

Bullettin board and post-it have been used also to build problem tree and objective tree; after discussions, comparisons and observations, post-it have been finally positioned so that key-problem and key-objective have been identified. The prosecution of methodology was connected to the fulfillment of Logical Framework Approach through identification of strategies, interventions and actions.

The involvement into the understanding and evaluating process of subjects, as young people and operators in the context of young policies, able to contribute to discussion with a justified opinion (Grea, 2000) has been the essential requirement for the efficacy and utility of developed activities. Research conclusion and results interpretation are described in the following paragraph.

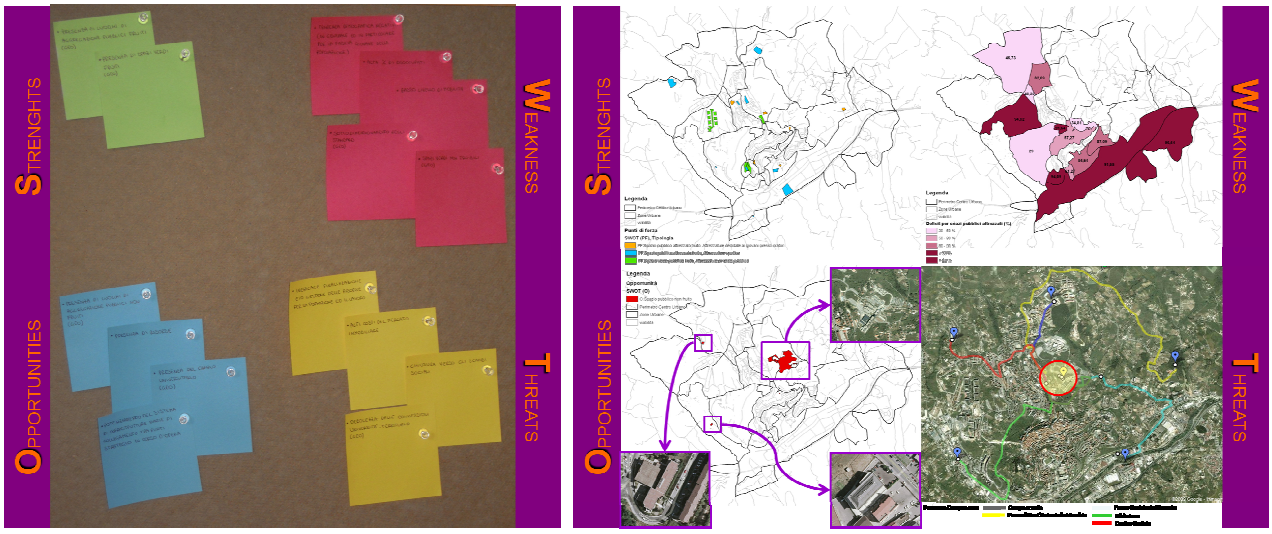

Fig. 3: From "post-it SWOT" to "GEO-SWOT": experiment in a focus group

6 RESULTS AND FURTHER WORK

The result of the simulated process, at this moment, has been the formulation of a set of five strategies that, on the opinion of focus group, must be adopted to improve quality of young people life in the town. Surprising result is that participants have underlined that Public Administration can not work alone, but need the contribution of citizens themselves; young people have been positioned at the centre of strategies but, more important, at the centre of planning process. Participants expressed the opinion that their engagement can be strategic for success of planning activities.

Moreover, thanks to the friendly environment where focus group meetings have been held, thanks to the pleasant mood of meetings, thanks to the introduction of enjoy into participation activities, they seem persuaded into a future involvement in planning processes.

This planning process simulation shows that citizens (young citizens in particular) strongly contributed to the initial phase of planning process, when moderators guided and helped them into the context analysis, built through technical analysis (such as quantitative measures and so on) but also through citizens'tested knowledge; moreover, citizens followed planning process and became strategic actors into participation phase. In fact, they where involved at the start point of planning process, they were conscious of process itself, thanks to the involvement in initial phases, they felt free to act into participation process, built in a not-formal environment, with characteristics of a play. Synthethically, citizens felt better and contributed to plan building more and better than with traditional participation forms.

The research has tested the interest of young people toward participation in planning process, also with a rational approach, normally considered boring and strictly technical. Experience highlighted the possibility to make amusing this rational approach, and his effectiveness thanks to the creation of a playful climate and the support of web 2.0 tools. Starting from this result, the future development of research will be the involvement of young participants into Playful Public Participation activities, with organization of role-playing games, experiences of planning for real, building of future scenarios, but also the use of Internet for electronic vote to evaluate strategic alternatives. It will be in that moment that we could start to experiment the "rational+playful" approach in participated planning processes.

7 ACKNOWLEDGEMENTS

Thank you to David Prosperi and Alenka Krek to trust in us and for their constant encouragement.

Thank you to Centro di Aggregazione Giovanile (Potenza, Italy), to support our activities for the case study.

Thank you to LISUT (Laboratory of Urban and Territorial Systems Engineering) Research Group of University of Basilicata (Potenza, Italy) to permit us to lead our researches.

1 ABSTRACT

The ideas of innovative urban planning are not strange in Poland. Good practices from Western Europe and USA are known to architects, urban geographers and other professionals. Discussions about urban planning are not only pragmatic, but also strongly ideological. However, the everyday planning experience is far away from sustainability path. We often ask ourselves a question, why is it so difficult to make cities in Poland more liveable? Apparently they are still to strong rooted in the past to move forward to the future. Although many things have changed in the last 20 years, a comprehensive, long-term urban planning is missing.

In this paper we identify some processes characteristic for contemporary urban development in Poland. We argue that these processes – being usually results of developers' activities rather than urban planning - do not lead towards liveable cities, but rather towards socially segregated and unsustainable cities. We also suggest some solutions to improve the urban planning system. Polish cities need a new applicable planning approach, because the current one fails to coordinate large public and private investments.

Our methodological approach is case study analysis. We have chosen the city of Poznań, the fifth-largest city in Poland and the third-largest academic centre. Poznań, as one of leading national economic centres, is changing its spatial structure very rapidly, but there was surprisingly little research on that field. We believe that the results of our analysis can be transferred to other second-order cites in Poland and perhaps to other Central European cities as well.

2 POLISH CITIES AND THEIR CHALLENGES

At the beginning of the second decade of 21st century the major Polish cities face a continuous and serious competition for the second (behind Warsaw, the capital of Poland) position in a range of most attractive places to live and work in Poland. However, since the accession of Poland to the European Union (2004) this very race to the new, better position has become no more local but, in fact, global. In a new political and economical configuration literary every city, aware of the global positioning game, must consider its own present status, dynamics and destination of development and choose the right strategic methods to reinforce its own advantages, eliminating shortcomings at the same time. In the case of Poznań, a city of one of the most dynamic economic growth of last years, yet most expensive conditions of living, the situation is not entirely clear. Even recently declared official Development Strategy 2030 does not define properly its present condition, desired destination, instruments or possible threats. The city of Poznań begins this race being once a true leader, but already an overrated veteran who believes that perpetuating its own legend is enough to win the competition.

In the following paper we identify and describe several processes which are crucial for the current stage of urban development in Poznań.

3 HOUSING MARKET – IS HOUSING AFFORDABLE?

Liveable cities are cities where people of different income and social status live next to each other in the same neighbourhoods (Jacobs 1993). In order to achieve this social mix, it is necessary to provide subsidised housing (also called social or public housing) to the low- and middle-income groups, who cannot afford a dwelling at full price. Although it is arguable, whether a more regulated or more liberal form of subsidised housing is optimal (Hackworth 2007), it is generally agreed that it is a necessary supplement for commercial housing.

Many Polish cities have problems with insufficient housing supply, which date back to the socialist times. Under socialism, the state-controlled and inefficient housing market could not cover the demand, which was rapidly increasing due to industrialisation and inflow of workers from the rural areas. At the same time the old pre-war housing stock was underinvested and was gradually falling into decay. Housing shortage poses a serious problem, even many years after the fall of socialism. In the year 2002, 13 years after the political

change, there were in average 117 households for each 100 dwellings in Poznań. Many families live in small, overcrowded dwellings, because the average size of a dwelling is only 64 m2 and the living space per person is 27 m2.

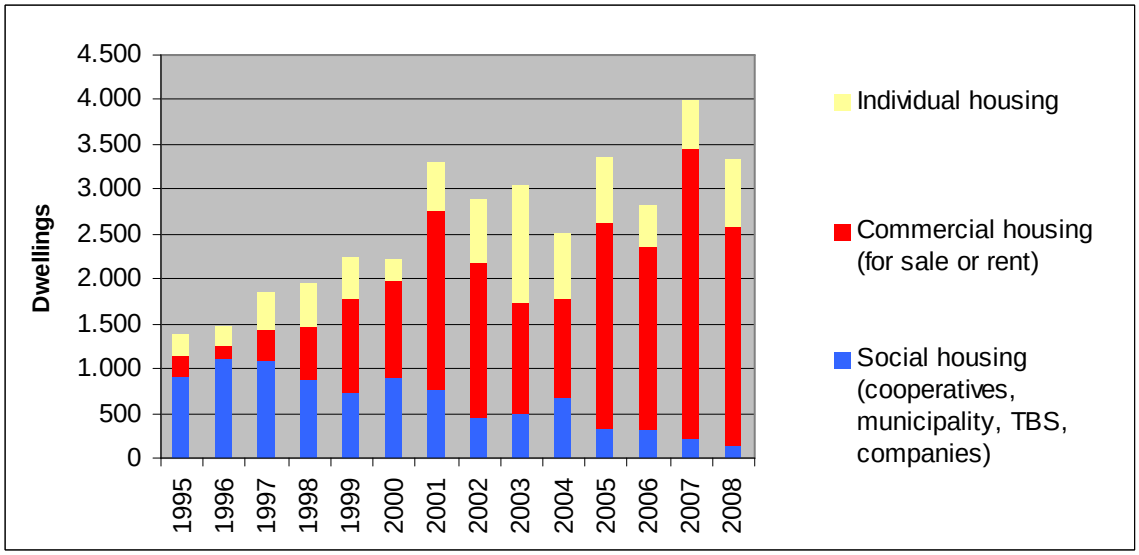

Fig. 1: Supply of social, commercial and individual housing in Poznań (1995-2008) Source: Polish Central Statistical Office (GUS).

Poznań has got vast demand for housing, because of its growing economy and the high share of young people (20- and 30-years old). The supply of housing has greatly increased in the last years, but so the prices did and are much higher than a few years ago. At the moment, it is very difficult to find affordable housing in the city. Housing supply in Poznań in the years 1995-2008 consisted of 25% social housing (including cooperatives, municipal housing, housing provided by companies to the employees, and TBS), 53% commercial housing (provided by private property developers), and 22% individual housing (self-build). In the last years the housing supply has increased, but only in the commercial sector, while the share of social housing is decreasing (Fig. 1). What are the reasons of this decline?

On one hand, some forms of housing supply, which were popular in socialism (housing cooperatives, dwellings for workers built by companies) have lost their significance after the political change. New forms of social housing are municipal housing and TBS (Social Housing Associations). TBS are owned by the municipality. The construction cost is partially covered by future tenants and partially by a preferential state credit. For that reasons, TBS used to be popular among young families and other middle-income households. Unfortunately, the construction costs have increased during last few years and it is very difficult for TBS to obey the cost limits (written in the law), so their market-share is decreasing.

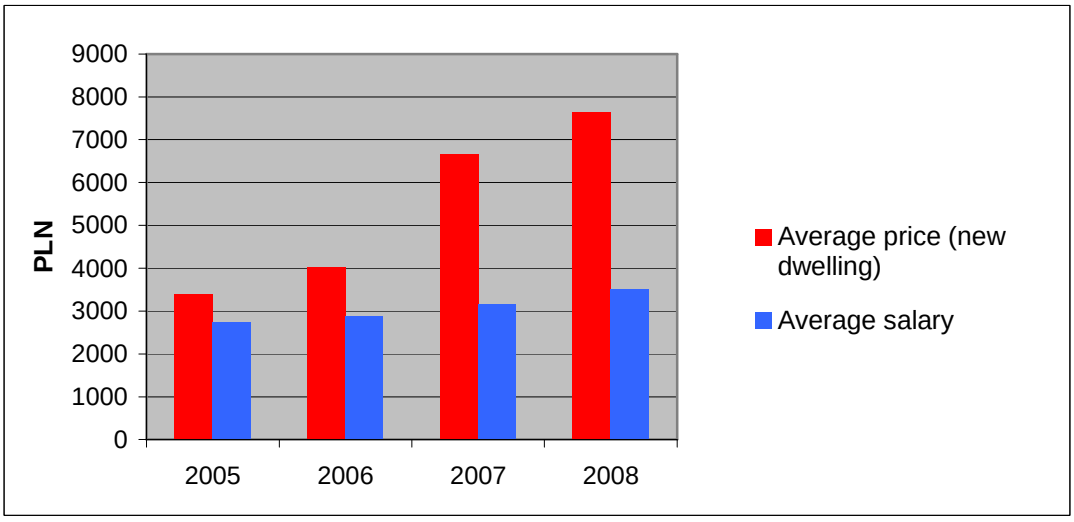

Fig. 2: Average housing prices and salaries (PLN) in Poznan (2005-2008). Source: GUS (salaries) and RedNet Consulting (housing prices).

On the other hand, the commercial housing developers are currently in a very good condition. High demand for housing is caused by young demographic structure (the baby boom generation of 1970s and 1980s is now in the matrimonial age) and increased buying power (economic growth, higher salaries, but especially easily available mortgages). Commercial developers can dictate the prices, which have rapidly increased for the last years, especially between 2005 and 2007. Unfortunately, in the same time, the average monthly salary has only slightly increased (Fig. 2). Whereas in the 1990s, the purchase of a dwelling was financed mostly by cash, today the mortgages have become more popular, but they usually contain high interest rate.

Since there is actually no supply of subsidised housing anymore, there are not many options for those who cannot afford a dwelling at market price. Rental market in Poland is small and, especially in university cities like Poznań, it is dominated by the students. Because of housing shortage, there are also not many dwellings on the second-hand market, and their prices have also increased considering last few years. Moreover, second-hand dwellings are mostly small dwellings in the post-war prefab housing estates, so they usually have only 2 or 3 rooms, or in the old pre-war housing, which have not been renovated since many years. Because of housing shortage, many young people and young families live together with their parents.

Last changes on the housing market stimulate residential segregation. Because of extremely high housing prices and decline of social housing, only the well-off households can afford a new dwelling in Poznań. Low income households (the elderly, the unemployed), which often live in very bad conditions, are actually excluded from the housing market, and the middle income households usually move to the suburbs, where the price levels are lower. Poznań has got a strongly negative migration balance with its suburbs, and the suburbanisation process is gaining momentum (Beim 2009).

4 URBAN RENEWAL AND REDEVELOPMENT – A FORGOTTEN ISSUE?

Urban renewal in Poland is an urgent issue, which has been neglected for many years. There is a huge renovation gap, because during the socialist period there were actually no renovation principles for the pre-war housing stock. Private owners could not afford renovation, because the state-regulated rents were extremely low.

Urban renewal, after the fall of socialism in Poland, is a very slow and difficult process. Unlike in Eastern Germany, where most of old housing stock has been renovated already for the 1990s (thanks to large money transfers from the well-developed western part of the country), for many years after transformation there was no financial support for urban renewal in Poland. This situation changed a little when Poland became a member of the EU and received support from the structural funds. Many cities have prepared special revitalization programmes in order to receive European funds. Among them, Poznań passed the revitalisation programme in 2006. However, EU funds are available only for specified projects, except for housing. Apart from the EU funds there is no other chance for significant financial support, so the urban renewal is, in fact, a marginal subject within the local policy.

The maintenance of old municipal housing stock is expensive. Thus, many dwellings have been sold to the tenants during last years. The tenants could afford the ownership status, because they were granted a large discount off the regular price. However, many of them will not afford renovation because of low income. The city of Poznań renovates its housing stock very slow and inefficiently; renovated dwellings are rented or sold at the market price, while the former tenants are moved to other (mostly peripheral) locations.

The inner city of Poznań has maintained (continually) a mixed social structure, but the filtering process has already begun. Wealthy households are constantly moving toward new suburban housing complexes, while the elderly, the unemployed and other low-income households stay in decaying old houses. The City of Poznań estimates that about 20,000 people moved out of the inner city during the years 2000-2005 (Miasto Poznań 2006).

Surprisingly, plenty of high-quality housing projects have been released within the inner city of Poznań during last years. A similar trend has been observed in the Western Europe, where it was called “new build gentrification” (Davidson, Lees 2005). However, in the case of Poznań, this process is not a mere continuation of gentrification. It is rather a kind of substitute for it. Beim and Tölle (2008) pointed out that the main factor behind the decision of moving into new owner-occupied dwellings in the inner city of Poznań is not the inner city milieu, but pragmatic reasons. A displacement of residents from old housing

districts has not taken place so far because of the ownership structure (many dwellings are owner-occupied) and because the construction of new dwellings is more profitable (for developers) than renovation is.

Some parts of the inner city are especially desired by developing companies: the surroundings of Old Market Square, the banks of Warta River (Fig. 3), and specific areas surrounded by parks. New housing often contrasts with historical pre-war brick houses and its derelict surroundings. New inner city housing complexes pose a sign for growing inequalities and segregation. The so-called "apartments", sometimes equipped with exclusive facilities such as swimming pools and fitness centres, are emerging next to historically valuable, but decaying old houses.

Fig. 3: Gated community at the bank of Warta River in the inner city of Poznań (in the background the cathedral). The fence not only isolates the inhabitants from their neighbours, but also separates the public from the river. Photo: A. Radzimski

It is difficult to predict what the future of inner city in Poznań will be like. One should not expect large financial support for urban renewal in the next few years, except for support from the European funds. Private capital is more interested in new construction, which is more rentable, than in renovation of old buildings. Population decline did not cause large vacancies so far, as many dwellings have been rented by students, or converted to offices and shops. However, in the long term this demand will decline and more vacancies may appear. The worst possible scenario presumes old housing to be demolished to vacate a construction site for new apartments.

In the year 2008 the Old Town of Poznań was announced by the President of Poland as a monument of history. This declaration means that the Old Town should be protected with regard to its historical and architectural values, to mention only a few: Poznań was one of the first capitals of Poland in the medieval ages, from 15th to 18th century an important centre of trade and culture, and a centre of independence movement under the Prussian occupation. However, current neoliberal policy, which neglects old housing stock and blindly approves new large projects poses a threat to the historic legacy.

5 MAIN STREETS VERSUS SHOPPING MALLS

Poznań represents one of the most interesting urban layouts of nearly ideal, oval city centre designed under restrictions of 19th century Prussian polygonal fortress. Main city streets and squares remain to present day the most recognizable and legible elements of urban composition. In the socialist period there was an attempt to radically rebuild the existing city centre, which was in a half destroyed during WWII, and - what was even more important - to alter its image in a modern manner. Once the deconstruction had begun, it has never ultimately been completed within designed range, mostly because of financial shortcuts. After the end of the socialist era there were no urban interventions of such scale and impact up to present day. In fact, during last 10 years there were significant improvements and renovations of main city squares (except for the most important one – the Old Market Square, where an architectonic competition was held in 2008, but no 1st

prize was appointed). Public space improvements can be characterized within three categories: technical and aesthetical improvements (infrastructure and surface replacements, public green refinements) – Ratajski Square, Wielkopolski Square; conservative and prestigious improvements (restoring the pre-war functional and formal layout of public space) – Liberty Square; formal and legislative improvements (creating formal plans without proper formal tools and financial background to realization) – Spring of Nations Square. None of these implied any wider spatial context or general revitalization purpose.

Moreover, several distinctive municipal buildings were refit due to European Union funds, but it has not implied any real, general revitalization of the city centre as a whole. There was neither clear and consequently implied strategy for renovation of building substance and improving spatial-functional integrity nor any systematic efforts leading to functional improvement or reorganization of transportation network and public space enhancement. All of this along with the situation of considerable free market influence upon the spatial design of a city and its agglomeration (urban sprawl) and visible symptoms of city centre depopulation led to significant loss of competitiveness of inner city areas. There were some remarkable architectural landmark realizations (e.g. Old Brewery Business and Art Centre) which (in some sense) altered the hierarchical order of the most important destination points of the city centre, but did not cause revitalization "chain reaction" within their direct urban neighbourhood, as it was frequently claimed and somehow expected.

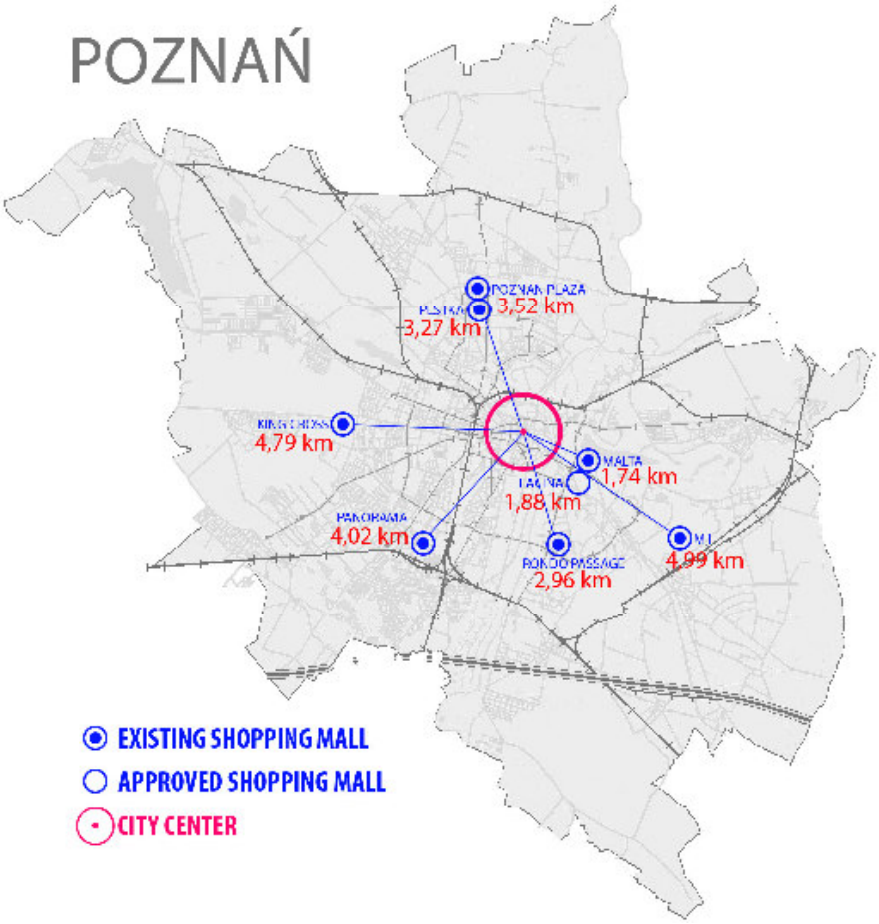

Fig. 4: Approximate distance between the biggest shopping malls and the city centre (town hall tower). The two closest ones (Malta, Łacina) placed within 2 km perimeter. Food discounts and construction markets were not included. Source: own compilation.

However, in contemporary conditions, there are significant but unplanned transformations of public realm in terms of functional alterations. This particular phenomenon is manifested by progressive but inevitable relocation of retail shopping and entertainment from the inner city into huge shopping malls, which are planned and built too close to the core of the city (Fig. 4). Hence, the influence of the big box stores on the functional domination of the city centre can and will be tremendous. For example, in only 500 m distance from the up to now biggest in Poznań "Galeria Malta" (54 000 m2., source: neinver.com) an even bigger "Galeria Łacina" (108 000 m2., source: lacina.pl.), was approved by local authorities. Such "synergic" effect in combination with lack of commercial rent policy and control in the centre caused the interchange of

commercial and shopping services (along main streets) into mainly banking agencies. These were the last ones, which could bear extortionate rent claimed by downtown tenement owners. For the same reason, high specialized stores, hobby centres, pubs, antiquarian bookshops, antique shops, small theatres or small designer stores and studios are consequently disappearing from the main streetscape. This phenomenon, along with lack of smart transportation policy within the city centre, and of an operational revitalization program, might be spatially, functionally and demographically devastating for the character of urban core. According to the new development strategy, an exclusion of selected main streets from downtown traffic will not be released before year 2040, while full bicycle route system could be implemented not earlier than by year 2025.

Although the concept of connected and vital public space network remains underinvested and diminished, there are noticeable declarations to redevelop former transportation and post-industrial areas (brownfields). In the first case (west part of the city centre) a vast enterprise of redeveloping old central city train station simultaneously with train (active) area – designed as the Integrated Communication Centre – would be an asset to the long lasting integration of main city train station and civic areas of the city. The declared term of realization (the European Football Championships 2012) may be difficult to keep, considering a conceptual stage of the project. In the second case (east river bank downtown area), a degraded post-industrial infrastructure (old gas-station facility) were declared as a potential new cultural centre (with the realization budget of approximately total 500,000,000 PLN) as a key enterprise in complicated process of restoring degraded river banks in Poznań centre area. Unfortunately, there is little chance to realize this one, without a serious (or total) share of private sector.

6 TRANSPORT POLICY – TOWARDS AUTOMOBILE DEPENDENCY

Automobile has become the most popular mean of transport in Poznań. The last traffic analysis done in 2000 shows that 53% of trips have been done by car. Modal share of public transport is 37%, pedestrian traffic 8% and bicycle traffic 2%. It is assumed that present modal share of automobile traffic is much higher because the number of local public transport passengers has fallen and the number of automobiles has grown up. The motorization level in Poland has been regularly growing up since the beginning of free market economy in Poland. In 1990 the motorization level in Poznań was 222 cars per 1000 inhabitants. During the transformation the motorization level has increased to 345 in 2000 and 496 in 2008. The fastest motorization growth was observed during five years after the fall of communism. Then the motorization level stabilized and started to grow again since 2004, the moment of EU accession. However, the tax-free import of old cars from Germany should not be perceived as the main cause of this growth. The main reason seems to be huge suburbanization and changes in living and transport behaviours.

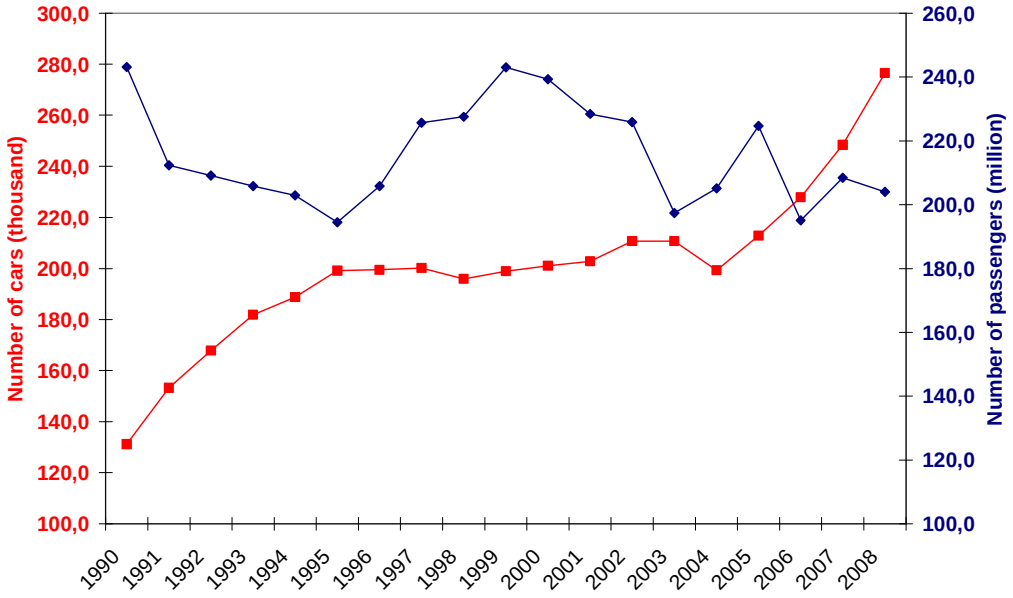

Fig. 5: Number of cars in Poznań and number of passenger of Poznań urban public transport a year. Source: own compilation based on GUS.

Since 1999 Poznań has had a formal transport policy. Although the main goal of Poznań transport policy is sustainable development, this document does not designate measurements of sustainability and does not specify particular tasks to perform in detail. The term "sustainable development" is usually interpreted in Poland as "balanced development" or "even development". Whatever the case, real policy is actually more car-oriented. With the exception of the old town area there are privileges for automobile traffic, and more amenities for cars are planned. The city's plans to develop public and bicycle transport infrastructure are incommensurate with road infrastructure.

Misunderstanding of the idea of sustainable development has severe implications for municipal budget and investment processes. For several last years the average expenses for development and maintenance of roads were on level of 400 - 500 million PLN, while expenses for public transport were about 150 - 200 million PLN (the netto sum – a difference between incomes from tickets and costs of maintenance). Main part of road expenses are investments (about 70-80%, depending on particular year), while main part of public transport expenses are subventions for local public transport. Only several percent of this amount (10% - 40 %) have been spent for new investments. Ticket sale revenues cover approximately 45% of public transport costs, and this share is decreasing. Yearly expenses for new cycleways (constructed apart form new road investments) are on a level of 1 - 2 million PLN. Half of this sum has been spent for new pavements, usually within new districts.

Rising motorization forces municipal authorities to continuous improvements of car traffic. It is continuously being done by two ways: the development of new roads and "small improvements", like intelligent traffic lights or extensions of existing intersections (new lanes, etc.). In some cases intelligent traffic lights improve capacity of streets by 30%. In 2007 alone, Poznań had about 200 traffic light installations. On almost 50 intersections, traffic lights give priority to the public transport. Intelligent traffic lights can be an important tool for sustainable development, but they can be used for car-oriented transport policy as well. In Poznań this system was applied with two main goals in mind: to improve road capacity for automobile traffic, and to improve conditions for public transport on some intersections, which are mostly overcrowded by trams or buses. The main losers of the intelligent traffic lights system in Poznań are usually pedestrians and cyclists.

The city has other plans for many small improvements for cars, for instance new parking lots in the city centre (officially, but inadequately called "Park&Go"), new roads to new settlements and surrounding communes. However, the most controversial and enormously expensive planned investment is a third bypass for the city, which is designed as an expressway (the "third ring"). If the General Directorate for National

Roads and Motorways (GDDKiA) had not taken the decision to construct of a fourth ring located outside the city limits, and what is even more important – outside dense development and residential area, the third ring would have had its advantage. Nevertheless, the city municipals have not changed their decision; what is more, parameters and localization have remained the same, but now instead of being a bypass of the city, the third ring should improve car traffic and ensure that each trip between any points of city would take no more than 25-30 minutes. Since no public transport will be allowed on the new bypass, it will even worsen modal split and privilege automobile traffic. In order to cover the estimated cost of the 36 km long third ring, which is up to 9 billions PLN, the city would have to largely increase the municipal debt.

In the case of public transport, the city plans to extend two tram tracks: to a huge shopping mall in Franowo district, and a relatively short extension of Poznań Speed Tram (PST) to the main rail station. First investment is needed to build a new tram depot, because the old one, located close to the city centre, was sold to a private developer, who is planning to build a shopping mall and apartments. The extension of Poznań Speed Tram allows to bypass three overcrowded intersections in the city centre and fasten trams going to southern districts of the city.

The only restriction for the automobile traffic (excluding closure of some Old Town's streets) is a paid parking zone introduced in 1993. In 2003 it was broadened and covers at the moment about 7,000 parking places. There are some plans for a further extension in 2011. The biggest disadvantage is that drivers do not have any alternative, because the introduction as well as the extensions of paid parking zones were not followed by new measures like Park&Ride system, cycle facilities in city centre or others.

7 SUBURBANISATION – DREAMING ABOUT OWN HOME AND GARDEN

Poznań metropolitan area has been witnessing a self-sustaining suburbanization process for at least two decades. All the characteristic features of suburbanization process can be identified, including: population decline of the inner city accompanied by population growth of the entire metropolitan area, negative migration balance of the central city accompanied by positive migration balance of suburban communes, and a dynamic growth of housing development outside the city limits. Additionally, residential mobility is also observed within the city limits, from the central districts to the peripheral ones.

The suburbs of Poznań are witnessing the features of urban sprawl. Many new estates are established without connection to existing settlement structure. Delivering public transport service to them will be very difficult (if not impossible) in the future, due to their random location, low density and the existing road system. Moreover, the metropolitan area attracts a growing number of new single-function facilities, e.g. shopping malls, industrial zones, technology parks. Private cars are the only means of transport assuring efficient and rapid transfer between these spread sheds and compounds.

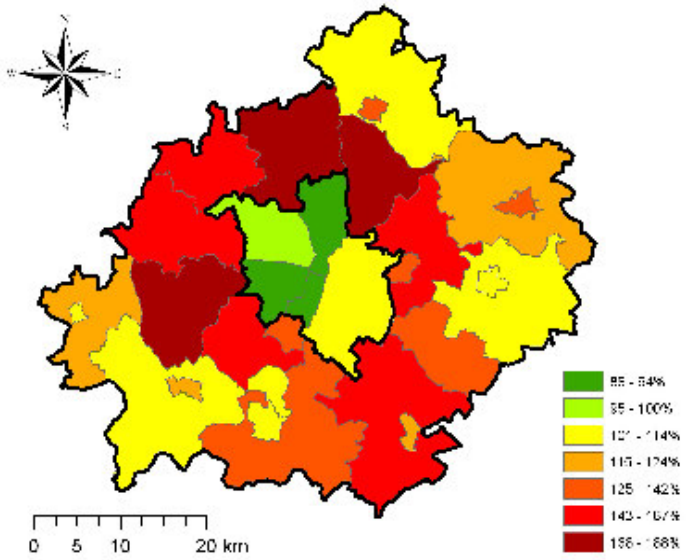

Fig. 6: Population changes in the Poznań metropolitan area 1990-2008. Source: own compilation based on GUS.

The period from 1990 to 2008 could be divided into three characteristic phases of suburbanization. The first phase (mid-1990s) concerns migrations resulting from completing large socialistic investments in multi-

family housing commenced back in the 1980s. The second interval occurred in the mid-1990s when housing market witnessed a downturn: the number of new flats for sale dropped by 50% against 1990, hitting the lowest level in 1995. Housing development slowdown triggered weaker population growth in all communes of Poznań agglomeration, which persisted until 2000. Since then, unlike any time before, the number of inhabitants in the satellite towns has been growing rapidly.

Fig. 7: "Change your neighbour – change your address" Advertising campaign of a mortgage bank (2007). Photo: M. Beim.

According to statistical surveys (Beim 2009), the main reason for migrating to the suburbs of Poznań was inadequate housing space – usually too small. The decision of moving out was also affected by high noise level in the former dwelling as well as improved financial situation. Further, the change of dwelling resulted from high costs of living, air pollution in Poznań and changes in family situation (like marriage or birth of a child). Other factors, like relations with neighbours and safety in the former place of living, were of little importance.

Suburbanization in Poland is strengthened by a new culture pattern of a young family, which has an own home with garden and uses cars for literary each trip. This pattern is deliberately repeated in most popular Polish serials, women's magazines as well as developer's advertises. Simultaneously, the disadvantageous image of old districts and public transport is promoted. Suburban house has become one of the biggest dreams for Polish yuppies. The only exception from this is a gated community.

8 CONCLUSION

In May 2007 the ministers responsible for urban development from all EU member states committed themselves to support sustainable development of cities (cf. Leipzig Charter on Sustainable European Cities). After three years, however, this document remains (at least in several countries, like Poland) only a declaration. Modernisation pattern of Polish cities is driven by urban sprawl and automobile dependency, which are accompanied by inner city decline, privatisation of public space and growing residential segregation. Of course many of these problems (if not all of them) have occurred before in Western European and US cities. It seems that the best way to learn is to learn on mistakes (in fact, own mistakes).

Poznań is a figurative example a city which does not use all of its development chances. At the moment there is no long-term, sustainable and integrated development policy in Poznań. Development decisions are driven by demand for land, or in other words, dictated by developers, without paying much attention to the existing urban structure. Inner city buildings and public space are falling into decay, while the outskirts and suburbs are filling with urban sprawl, accompanied by rising automobile congestion.

The most important impulse for changes in the model of urban development in Poland was the socio-economic change that took place after 1989. It included liberalisation of building regulations and making the purchase of a car more available. First symptoms of change were new shopping centres, open in mid-1990s. They were located within the city limits or in surrounding communes. They showed the real power of individual motorization and the potential of suburbs. But still, the number of people and shops moving to the suburbs was not very high - until the late 1990s.

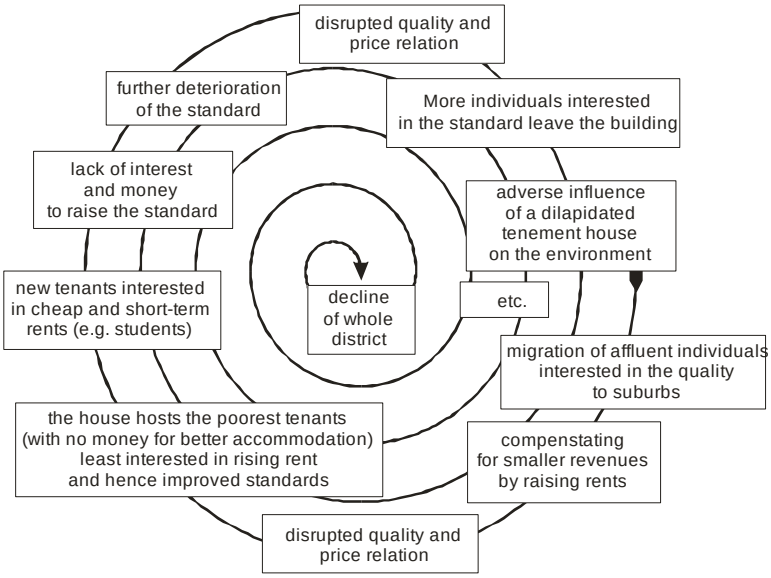

Fig. 8: The relation between the more affluent social groups' migration to suburbs and decline of a district. Source: Beim 2009.

Residential migration was followed by increasing motorization, thus contributing to mounting transport problems and ensuing further deterioration of environmental conditions. Urban sprawl, which is currently taking place, is destroying one of the greatest advantages of old urban planning: "the city of short ways", and results in higher modal share of automobile traffic. The inhabitants of suburbs do not have any real alternative, because there is no comparable (in terms of efficiency) public transport. The growing number of journeys by car has been topped by longer commutating routes after migrating to the suburbs. All of this leads to growing automobile congestion in the city and surrounding communes. This, in turn, contributes to further deterioration of environment, especially in the city centre, what induces even more individuals to change their place of living. Hence, a change in their transport behaviour patterns is initiated. City becomes increasingly sprawled. A model of this process is presented in Fig. 8.

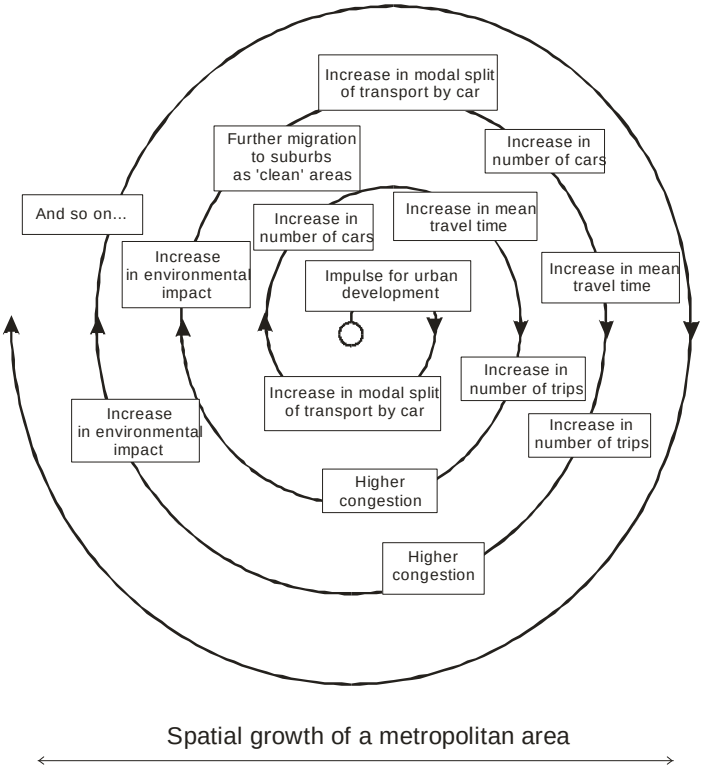

Fig. 9: Connection between the development of suburbs and growing traffic congestion. Source: Beim 2009

Spatial development of suburbs boosts commuting costs, and thus the costs of living; on the other hand, the depopulation of tenement houses and blocks of flats leads to ever worse living conditions and increases rent. The owners, unable to meet operating costs or to find new tenants, often raise the rent for remaining lodgers,

thus forcing another group of people to move out, usually to the suburbs. As a result, the old districts are settled by groups of short-term occupiers, e.g. students. They are not interested in improving the quality of flats and houses, as it leads to higher rent. They are trapped in a vicious vortex. Growing costs of living in the city centre offsets the effects that the rising costs of suburban living (e.g. travel costs) could have for curbing growth of the suburbs (Fig. 9). Similar relation can be shown for retail trade within main streets. The tenement owners would like to compensate looses and rise up the rent. More and more shops move to shopping malls, or simply close down. After several months vacant places are rented for cheep groceries or for trade not welcomed in shopping malls.

9 POLICY RECOMMENDATIONS

Many changes are necessary in order to make Polish cities more sustainable. First of all, it is necessary to change the planning law. There is a need for long-term comprehensive planning instead of short-term demand-oriented planning, which is currently a common practice. Many instruments, which proved to be successful in other countries, could be also applied by Polish cities, for example urban growth boundary, transit oriented development, urban codes, and regional planning. There is a need for cooperation with communes of Poznań agglomeration in the field of housing and transportation planning, but there are practically no instruments of regional planning in Poland at the moment.

However, during last years Poland has been witnessing a public debate concerning liberalisation of planning law. The lobby of developers aims to make planning rules more liberal, although the current act from 2003 is much market-oriented. For example, there is a regulation called “good neighbourhood rule”, which allows to build a house or a housing complex in the absence of local land use plans. The location decision is approved on the base of few basic parameters (for example, access to public road, plot coverage), even if it does not comply with the masterplan of the whole city. Local land use plans usually cover only a minor part of the city, so the “good neighbourhood rule” is being abused, contributing to urban sprawl. More than 80% of new housing in Poznań during the years 1999-2007 was built without local land use plans, i.e. without comprehensive long-term planning. As a result, the vast majority of new housing does not have direct access to public transport and other facilities (Radzimski 2009). It is very probable that in the next years the short-term demand-oriented planning paradigm will be still dominating. Because of developer lobbying, the parliament voted in 2008 for easier conversion of agricultural land into building plots, although this decision was criticised by planning experts and vetoed by president Kaczyński.

Poznań, which is a young and dynamic city, needs a long-term development strategy aimed at reducing suburbanisation and promoting in-fill development within or adjacent to existing urban structures. Students, who are a huge demographic potential, should be encouraged to work and live in the city after degree. Today many young people are pushed out of the city because of extreme price and rent levels, so more social housing is necessary. It could be built in cooperation with private developers, but on municipal land. Social housing would reduce price levels and increase affordability of housing, since there is a shortage of ca. 17,000-22,000 dwellings in the city. However, extensive single-family housing cannot be a successful solution to the housing question.

Parallel to the housing programme, the attractiveness of inner city should be raised by improvements of public space and reduction of automobile traffic. To make inner city streets more liveable, local authorities should encourage social and cultural use of vacant buildings in cooperation with landlords. Local and national authorities should concentrate on the problem of inner city decline and grant financial support for urban renewal and redevelopment. High property taxation of derelict land in the inner city should discourage owners from speculation and promote investment. On the other hand, land value tax should discourage from development in the distant suburbs.

Last but not least, there is an urgent need to redefine the way how the urban planning students are taught. The academic practice shows that what students actually learn about planning is how to make plans for greenfield investments. One can expect that the graduates understand planning as a technical activity, not as a process. Therefore, new elements need to be introduced into the courses, for example: urban renewal, public transport planning, and traditional neighbourhood design.

Assessing the quality of life (QOL), its significance in urban planning and the feasibility of establishing a Quality of Life Reporting System (QOLRS) in cities, the historic city of Esfahan as the case example

Daryoush Moradi

(Daryoush Moradi,Urban and Reginal Planning Ph.D student, Faculty of Architecture & Urban Planning, Sh.Beheshti University, Tehran, Iran, daryoush_moradi@yahoo.com)

1 ABSTRACT

Quality of life (QOL) represents the level of welfare as recognized by the people. Its key concept is the recognition of every single individual's expectation from life and its quality. Besides, the QOL introduces the differences between the hopes, wishes and expectations of individuals as against the opportunities and limitation of each society. In this paper the QOL concept, the community trends approach and methodology of launching a Quality Of Life Reporting System (QOLRS) are applied not only to assess the QOL and its impacts on the urban planning system in the historic city of Esfahan, but also to test the feasibility of launching a QOLRS in the city chosen as the case example, i.e., Esfahan. To reach this aim, information about the measures and indexes of QOL are obtained from two different streams, one from the official sources and the other through the direct contact with the citizens. After analysing the results, this assessment revealed the fact that the differences in the quality of employment, population resources, and community affordability measures were higher. While, despite a high degree of difference between the applied QOL measures, the difference in community stress, community participation and community safety measures are noticeable. The results also indicated the possibility of establishing a QOLRS in this city based upon the information sources used in this study, as well as the prospects of enhancing the urban development planning and management procedures through setting up an adapted process of organizational framework and control mechanism, production of planning visions and goals based on community agreements and evaluation and decision taking processes. Also it was deduced that the QOLRS can produce an appropriate blueprint for reaching consensus and a common language between citizens, planners and urban decision takers in a sectoral and centralized planning system of this city. The paper emphasises the necessity of reaching an integrated urban planning and management system through a well devised set of improvements to the inter-organizational relations and structure of the cities in general and this case example specifically.

2 INTRODUCTION

The view of enhancement of QOL has been used in urban planning and urban development, in many countries, particularly the more advanced ones. The emphasis on the importance of human resources as the most important capital of a society is the highest characteristics of this view. Different countries according to their economic, social, cultural and environmental pecularities have used different methods to utilize the concept of QOL and its enhancement in their society. In this article with the use of the concept of QOL and QOLRS its attempt to investigate the QOL and its effect on urban planning in the city of Esfahan. The expecting aims are:

- Recognition of the concept and approaches of QOL and its application in urban planning.
- Assessment of measures and indicators of QOL in the city of Esfahan.
- Study on applicability of creating a QOLRS in city of Esfahan.
- Evaluation of the effects of QOLRS in the improvement of plan producing process, and urban management of Esfahan.

In this paper the QOL concept, the community trends approach and methodology of launching a QOLRS are applied not only to assess the QOL and its impacts on the urban planning system in the historic city of Esfahan, but also to test the feasibility of launching a QOLRS in the city chosen as the case example, i.e., Esfahan. To reach this aim, information about the measures and indexes of QOL are obtained from two different streams, one from the official sources and the other through the direct contact with the citizens.

In this regard, at the first stage the necessary informations and indicators to measure the QOL in Esfahan from formal anf informal sources and also through questionnaires from the residents of this city about their views were collected and compared with the information from Iran and also a developed country with ample experience in the field of QOL assessment and establishing a QOLRS, i.e., Canada.

At the second stage, the effects of QOL concept in the stages of a plan-making process which are affected most will be studied. The similarities of the plan prepared for Esfahan with the structure that is affected by the QOL concept and the adopted approaches have also been studied. At the last stage - with the integration of the results of this stage with the results obtained from the evaluation of the Esfahan's QOL, the possibilities of creating an appropriate QOLRS in this city - which has a centralized and sectoral planning system - will be examined. The result can be used as a device to strengthen the interrelation between not only the organizations but also all the stakeholders in a decision-making arena, to achieve an integrated urban planning and management system.

3 QUALITY OF LIFE CONCEPT

The QOL is the translation of social and environmental considerations in the process of urban plan preparation and implementation. The QOL concept can prompt the sustainable development and increase the sensitivness to carrying capacity of the earth and also the human capacity. This concept is the symbol of answering the needs of post modern era and follows a common ground to counter the spatial disparities. On the other hand, enhancing the level of the QOL is turned to be an appropriate device to achieve a better situation in the economic competition cycle, causing a move from a sole economic competition toward the competition of cities. The improvement of QOL in the cities can be considered as a condition in which the needs of societies to human resources and technological progress are achieved.

Within a planning framework, QOL represents the level of welfare considered by the people, and a key concept of it is the recognition of the expectations of every individual from life – in general - and from its quality. QOL represents the level of enjoyment of a person from the social and welfare services prepared for upgrading the QOL and consists of satisfaction and the opportunity to reach a situation which a person enjoys his/her life and also the disparities of hopes, wishes and expectations of an individual and his or her experiences from what is considered to be an acceptable QOL. Therefore the more the positive aspects and QOL, the more the level of satisfacation will be. (Smith, 1994; liu, 1974; Rogerson, 1998; cobb, 2000)

4 COMMUNITY TREND APPROACH

The existing approaches reletaive to the application of the QOL concept are "livability comparison approach", "personal well-being approach", "community trends approach", "wage differentials approach" or "market/resident approach". Among these approaches, some are based on the principles of economics, some on social sciences in general and also requirements of the ideology and also the practical aspects of planning. The urban decision makers which are pursuing the aim of correcting community relations that affect the QOL use the personal well-being approach. The economists and those groups advocating the economic development use the wage differentials approach and livability comparison approach, and those that hope to plan for upgrading the QOL of communities, use the community trends approach.

Urban and regional planners can use all the four approaches as introducted above, but it seems that community trend approach can fit better in planning and can better assist the planners. The reason for this is that first, this approach evaluates the trends and priorities of a community through time and consider these trends and changes as part of an ongoing process of development in any society. The second reason is that this approach encourages the discussions about the QOL indicators by the interest groups. Third reason is that the data used and applied by this approach from the facts concerning the QOL of the community can be considered as a set of appropriate foundation for decisions taken by all sectors of each comminity.

The foundamental prerequisities about the QOL issues of each society -based on community trend approach- are as follows:

- People are attracted to the places they like, and change the local conditions through time
- Mostly, people compare the QOL during a period of time and also compared with other places
- The political issues about the QOL and dicision making occurs within the boundaries of each urban area or each urban region
- The results of studies could only be valid if it is according to the ideas and views of local people of any community

Based on the aforementioned principles and prerequisites of this approach, the process of achieving favorable results in evaluating the QOL are summarized in five basic stages as shown in figure 1 (Myers, 1988).

Fig. 1: Five basic stages for measuring the QOL, source: Myers, 1988

5 LAUNCHING A QUALITY OF LIFE REPORTING SYSTEM(QOLRS)

In this paper an attempt has been made to utilize Federation of Canadian Municipalities (FCM) experience in Canada which comes below:

In 1996, FCM commissioned a study of how changes to the funding structure of federal transfer payments would affect municipal governments. FCM concluded these changes would have an impact on growing municipal responsibilities, but members lacked the tools and the data to debate this and other policies on behalf of their communities. To ensure a more effective voice in the future, the largest urban members of FCM recommended the creation of a reporting system to monitor the QOL in Canadian communities. FCM immediately began developing the QOLRS. By providing a method to monitor QOL and aspects of the social, economic, and environmental health of communities, as a tool to (FCM, 2001; FCM, 2002):

- Identify and promote awareness of issues affecting QOL
- Better target policies and resources aimed at improving QOL
- Support collaborative efforts to improve QOL
- Establish municipal governments as a strong and legitimate partner in public policy debates

5.1 Focusing on the QOL

The QOL measures reflect important dimensions of daily life at the community level. Public confidence in government and institutional leadership requires a focus on the QOL. QOL measures cross over sectors, programs and policies, putting the impetus on policymakers to make a link between what popular reports show and the experience of individuals and families. The QOL approach measures outcomes in "people terms" to encourage better communication between governments and communities, greater program transparency and greater accountability for results. The QOLRS is built conceptually on the initiatives outlined above (FCM, 2001).

5.2 Focus on outcomes

For the most part, the QOL concept is focused on measuring outcomes. Outcomes measurement is part of a public sector response that emphasizes accountability of public policy and transparency in the operations of public institutions. Leading-edge analysis is focusing on QOL indicators, assessing what actually happens to people as a result of social, economic and environmental changes (and, of course, of their own lifestyle choices), and on how well public policies serve to improve their life situation (FCM, 2001).

5.3 Information sources

Where possible, the information used in this reporting system has been obtained from national sources. Where special data runs were prepared, relating national measurements to community boundaries, the source notes indicate "Special Tabulations". The result is a powerful database for monitoring QOL, evaluating

policy outcomes, and researching evolving needs. The information in this report is only the surface of the database(FCM, 2001).

5.4 Information attributes

The establishment of a comprehensive QOL monitoring system is complex. The information has to be meaningful at the community level; available annually and on a nationally consistent basis; and be easily understood. Indicators have to reflect the various dimensions of living reality, and use the substantial existing research that has identified consistent relationships among those dimensions (FCM, 2001).

5.5 The QOL Measures

Eight complete sets of indicators are used for the QOLRS. A summary of the indicators follows (FCM, 2001):

- Population Resources Measures (PRM)

This is a profile of population characteristics, population growth, education and literacy levels, cultural diversity, immigration and the age structure of the population. It provides a basis for the monitoring of long-term demographic changes.

- Community Affordability Measures (CAM)

These measures compare levels of income with the cost of living. A higher affordability measure occurs when average incomes are relatively higher than average costs of living.

- Quality of Employment Measures (QEM)

These measures monitor employment dimensions and trends, such as equity and the distribution of employment, partial employment and unemployment among population groups.

- Quality of Housing Measures (QOHM)

These measures include the affordability of housing to rent (relative to prevailing incomes), percentage of homes in need of repair, vacancy rates and housing starts.

- Community Stress Measures (CStM)

These measures reflect social problems and they examine variables related to vulnerable groups. They include the incidence of low income, the incidence of lone-parent families, and the incidence of crisis calls, bankruptcies and suicides.

- Health of Community Measures (HOCM)

These measures reflect the rate of premature deaths (before age 75), infant mortality, the percentage of babies born with low birth weights, and workdays lost due to illness or disability.

- Community Safety Measures (CSFM)

These measures reflect rates of crime and violence, youth crime, and the rate of unintended injuries.

- Community Participation Measures (CPM)

These measures reflect the involvement of citizens in their community, and include political participation (voter turnout), daily newspaper circulation, charitable giving and support for community projects as measured by contributions to the annual United Way campaign.

6 QOLRS STRUCTURE AND ITS ESTABLISHING PROCESS IN ESFAHAN

QOLRS consist of subsystems of input, output, organizational structure, data processing and information transformation. These subsystems by itself are divided into parts. They have mutual relations with each other and have different inputs and outputs, and interact with each other with coordination. The inputs to the system are the information and data about the measures and indicators of the QOL which are obtained from different sources, and its final product is the report of the QOL. In every stage of this system returning to the previous stage and making necessary correction is possible (Fig. 2).

The condition for appropriate function of this system is the right relation between the parts of the system and true data and information entry. Continuation of different implementing stages, and a real reporting from the existing situation without any personal interference in the reporting of the QOL improves the efficiency of the result of the system and provides the study of changes in QOL in a single community and shows the positive and negative trends.

To commence the operation of QOLRS in Esfahan, seven consecutive stages were designed, as follows:

- To study the concept of QOL and getting acquainted with its special features
- Establishing different sectors of organization subsystem structure and coordinating them
- Collection of the QOL measures and its related indicators, considering the local conditions
- Creating the data and informations analysing subsystem
- Developing a saving opportunity and recycling and updating of indicators analysis results
- Preparing the QOL report
- Creating informations giving of QOL report and their interrelations

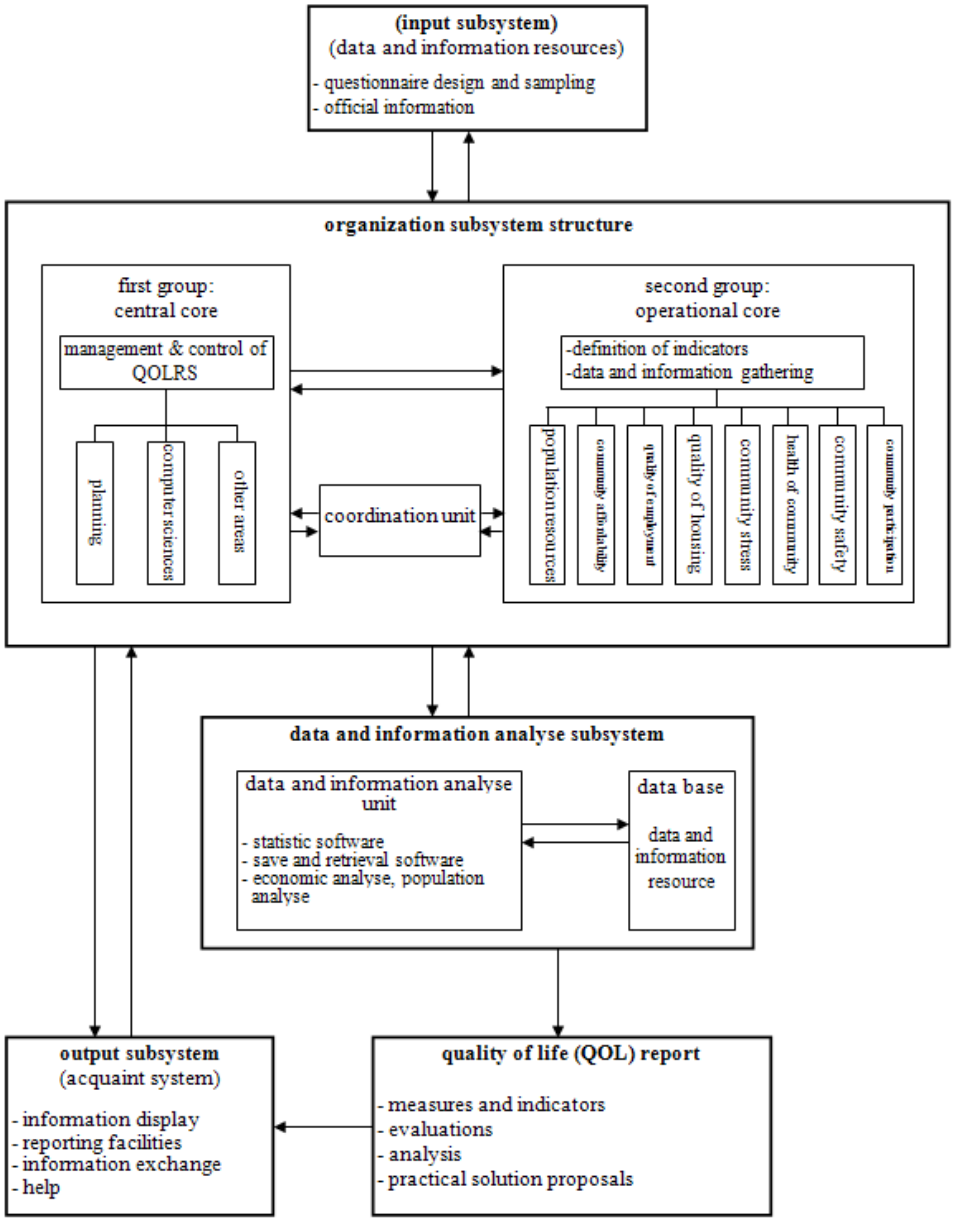

Fig. 2: QOLRS subsystems and their interaction relations as proposed for Esfahan, source: author, 2010, for this paper

7 ASSESSING THE QOL AND ITS SIGNIFICANCE FOR URBAN PLANNING IN ESFAHAN

In order to apply the QOLRS in assessing the QOL in Esfahan and reporting it, a six step process of analysing the QOL was designed, as follows:

- Introducing the measures and indicators of QOL used in the QOLRS
- Selection of the appropriate measures and indicators of QOL
- Gathering data on the indicators of QOL in three ways, namely, first by reference to the available official information of different public organizations, second through inquiry from the relevant expert officials and authorities, and third by conducting questionnaire surveys of people's opinions about their QOL
- Managing data on the indicators of QOL used in QOLRS by constructing different tables
- Comparing and interpreting the indicators of QOL in Esfahan and the indicators used in QOLRS in the Canadian cities, and comparing the findings with people's opinions
- Analysing for reaching the results about the findings of this search

Upon the implementation of the project, Esfahan was divided into 10 districts. To find about the citizens' opinions, the uniform random sampling method was used, and in total 50 surveys were conducted equally for each district. The surveys were completed by the citizens, experts, authorities, and the conductor. The questions were asked based on the measures and indicators of the QOL's information needs and those of the sampling population's characteristics. The information regarding the measures and indicators of the QOL was common among the citizens, experts and the authorities' opinions, and those of the official organs. This enabled us to use the data simultaneously and in combination in the QOLRS, and analyse the QOL accordingly.

The most important findings of the analysis of the QOL in Esfahan are presented below. This is according to the classification of the measures used in the QOLRS designed and proposed for Esfahan in this paper (the quantitative data are not presented here due to their large amount) [1].

7.1 Human Resources Measures (HRM): Information attributes

- The high proportion of the young population of Esfahan (%52.7 of total population)
- The very high population growth rate (%3.9 growth rate for 2 years)
- The very high labour force replacement ratio (2.5 new entrant people versus each leaver)
- A good quality general education while a very poor technical education (%13 versus %1.4)
- A very low labour efficiency and productivity rate (%34.9 of total labour force have no general and technical education)

7.2 Community Affordability Measures (CAM)

- low household incomes ($4273 per 1 year) and low cost of living ($4919 per 1 year)
- The lack of any financial savings due to the high costs of living as compared to the incomes, plus the ever-more financial vulnerability of households to financial crisis
- The increased imbalance of costs and incomes of the society's urban middle classes
- The high percentage of the urban middle classes (%77.9) and the less class differences in Esfahan in comparison to the whole country

7.3 Quality of Employment Measures (QEM)

- The high unemployment rate (%3.5) – especially the high long-term unemployment rate (%65.5 of total unemployment) – in Esfahan and the low employment rate of people within the age group who

[1] The quantitative data on the indators of the QOL were presented in the author's M.A thesis (Sh. Beheshti University, 2006) under the title of "Application of the Quality of Life Reporting System in Urban Planning (The case of Esfahan)"

are employed especially among the 15 – 34 age groups (%18.8) and the labour force aged 40 and above (%14.8)

- The high proportion of temporary employment rate compared to the permanent one (%61.4 versus %37.2)
- The low social support (%9.1) and employment insurance (%1.46) for the households as a result of the decreased job security and incomes
- The low average wage rates ($0.98 hourly)

7.4 Quality of Housing Measures (QOHM)

- The high housing rentals and purchase prices in Esfahan and the difficulty in purchasing or renting affordable accommodations of the lower income households (rent as a percentage of median family income is %41 and average price for a 2 bedroom apartment is $31555)
- The lack of welfare and safety standards in more than 70 percent of houses in the city
- Allocation of almost 41 percent of the income of households to housing

7.5 Community Stress Measures (CSM)

- low number of the lone-parent families (%13.3) and the low bankruptcy rates of the consumers and economical enterprises (9.8 per 1000 establishments)
- The high fertility per 1000 women aged 15-19 (92.8 per 1000)
- The very low suicide rate (near 0.0)

7.6 Health of Community Measures (HOCM)

- The high infant mortality rates (208 infant mortality per 1000 live births) and low birth weights babies (%3.6 of single births less than 2500gr)
- The low premature mortality rate (184 per 100000 population)
- The high hospital discharges rate (20057 per 100000 population) that decreased labour productivity rate

7.7 Community Safety Measures (CSFM)

- The increased number of crimes committed by the youth due to the higher proportion of Esfahan's young population
- The growing unsafety trend
- The lower rate of moral crimes (467 per 100000 population) in comparison to the financial ones (3695 per 100000 population) and the heavy injuries rates resulting from the committed moral and financial crimes

7.8 Community Participation Measures (CPM)

- The low community participation rate (%46.83) and the high fluctuating voting rates (from %29.5 to %63.7)
- The people's low level of awareness of their collective destiny and their little attention to the sustainability issues and the needs of future generations

8 THE ROLE AND SIGNIFICANCE OF THE QOLRS IN URBAN PLANNING IN ESFAHAN

Esfahan is the second industrial city of Iran which has historical and heritage importance too. Its historical importance goes back to many centuries back. This city - in its different historical periods - has sometimes reached its peak of fame and sometimes was led to its demise. The city of Esfahan prospered greatly during the 12th and 13th centuries and has many of its invaluable heritages from that period. Esfahan was selected as the capital city of Iran during the 16th and 17th centuries and it achieved greater growth and fame and was expanded. By the turn of the twentieth century, Esfahan, like the other Iranian cities, underwent dramatic

changes on the domestic and international scenes; and there was an increase in its urban growth rate, especially after the advent of the modernization movement in Iran in 1930's. At that time, Esfahan's spatial structure underwent a great deal of incompatible changes, e.g. new streets were designed, textile factories were established, and official buildings were constructed, and the city's infrastructure was renewed to include fire stations, and water and electricity networks, most of which were done without any well-prepared plan.

The first well-prepared urban development plan for Esfahan was produced in 1957 as part of the country's second national seven-year development program (1963-1956). From that time onward, seven plans has been made, including a comprehensive regional plan, three comprehensive urban development plans, and three detailed plans. Such plans aimed at controlling the landuse and urban growth rather than paying attention to the people's QOL. In this study, an attempt has been made to investigate the substantive issues and the implementation of urban planning in Esfahan, and to pursue the ways in which it was affected by the notion of QOL and to assess the degree of attention paid to the QOL in Esfahan and its urban planning. The QOLRS played a significant role in designing the organizational and control framework, and helped to devise the broad planning goals, to evaluate decision-making processes and its relation to the other urban planning aspects. This is illustrated in Figure 3, which shows the extent by which different Esfahan urban planning processes were affected by the discussed notion of QOL. No urban plan in Esfahan so far has intended to pay direct attention and to enhance the QOL as a definite and broad goal. This is while there are more points of similarity between the urban plans in Esfahan and the notion of the QOL in respect to gathering data, and less in respect to evaluating the planning goals (Fig. 4).

Fig. 4: The amount of QOL concept application in the most important stages of Esfahan plans plan-making process, source: author, 2010, for this paper

The QOLRS has attempted to enhance the quality of people's lives as the main goal of the urban plans; and therefore, it has expanded the horizons of the social, economical, structural and environmental issues. Thus, it takes into account all the public organizations and their behavioural structures and establishes relations between the citizens, the municipality and the other official bodies. The annual QOL report publications show the results of all the administrative bodies, organization performance, their strength and weaknesses, and their general development trends. It is possible to use all of the potentials and strengths of the officials and also the public opinions for the production and implementation of the urban plans in Esfahan. Hence, the QOL concept and QOLRS - as an applicable tool for urban planning - can provide a common language for the consensus of the urban policy making in a sectoral and centralized urban planning system, and to use it as a tool for a coordinated and an integrated urban planning and management (Fig. 5).

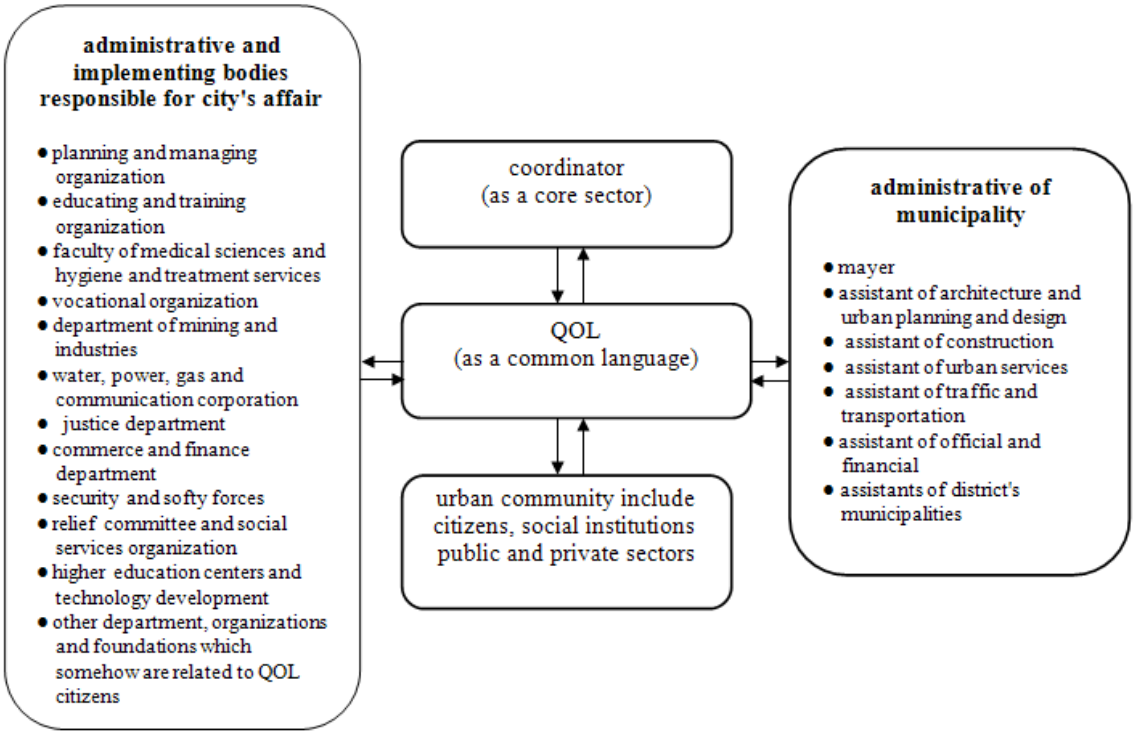

Fig. 5: The QOLRS as a common language to reach consensus in a cenralized and sectoral urban planning system, source: author, 2010, for this paper

9 CONCLUSION

The cocept of QOL can improve the urban planning to achieve community's goals and also create mutual relations between the planning policies and planning organisations within an urban plan-making process. The QOLRS may enable the application of the cocept of the QOL. Also undoubtedly it can achieve the urban planning goals and objectives without the need to perform a comprehensive analysis or have a repetitive work. The measures and indicators used in the QOLRS illustrate that in some aspects and in regards to the measures and indicators adopted, the QOL in Esfahan is not satisfactory and there is an urgent need to have more attention being paid to the QOL measures, quality of employment, human resources and community affordability measures and include all these in an appropriate and well-thought urban planning and management system. The problem is caused by failure - on the part of authorities - to notice and make due attention to the different aspects of the QOL in Esfahan and include it in an urban planning and management activity. This, in turn, results from the centralized and sectoral nature of the urban management in this city - and throughout the country - and the lack of local collaboration between the official bodies and all other stakeholders within the urban planning and management domain. One important and initial step to solve this problem is to promote the necessary collaboration between all the stakeholders – including local authorities - and to move towards achieving consistency of measures and coordinated actions. The QOL concept and the established QOLRS can very well work and be used as an efficient tool for efficiency of collaboration and mutual inter-organisational relations to make an integrated urban management.

1 ABSTRACT

Architektur hängt eng mit dem Begriff der Baukultur zusammen und den Vorgängen, wie der Mensch die natürliche und/oder bebaute Umwelt verändert. Im Gegensatz zum Begriff der Baukunst beinhaltet Baukultur alle gebauten Elemente. Beispielhaft sind hier Ingenieurbauten wie Infrastruktur- oder auch Funktionsbauten zu nennen. Baukultur beschreibt damit Geschichte, Tradition und Identität eines Landes oder einer Region. Im deutschsprachigen Raum sind einige Publikationen zu diesem Begriff erschienen [vgl. hierzu zum Beispiel Weeber et al 2005, Hutton 2005, Mittler 2005]. Dabei ist es jedoch sehr problematisch, dass der Begriff „Baukultur“ in seiner ganzen Bedeutung nur in einem kleinen Spezialistenkreis klar definiert ist, und die breite Bevölkerung, die bewusst und vielmehr auch unbewusst die Baukultur prägt, nicht versteht, dass sie ein Teil der Identität schaffenden Tätigkeiten ist. Bei Beobachtungen neu entstehender Gebäude oder Siedlungen wird dieser Trend vielfach deutlich: Häuser von Fertighausherstellern mit ortsfremden Materialien überwiegen in der Bauweise im Gegensatz zu einer zeitgenössischen aber dennoch regionalen Architektur. Eine Ursache hierfür ist, dass es kaum eine Publikation oder eine Möglichkeit gibt, sich schnell, regional und vor allem umfassend über qualitätsvoll Gebautes zu informieren. Vor allem das Fernsehen hat mit diversen Einrichtungsshows einen gefährlichen Trend zu dieser Beliebigkeit gesetzt. Eine Lösung dieses Informationsdefizits könnten Communities zu diesem Thema im Internet sein. Einen vielversprechenden Ansatz liefert das von der EU im Rahmen des eContentplus-Programms geförderte Projekt. MACE (Metadata for Architectural Contents in Europe). MACE verknüpft über ganz Europa und weltweit verteilte Architektur-Archive mit Datenbeständen über bereits realisierte und in Planung befindliche Bauprojekte miteinander und öffnet sie für Interessierte. Neben der Unterstützung zum Finden, Beschaffen und Nutzen einschlägiger Inhalte will MACE die Inspiration von Architekten fördern und insbesondere deren Aus- und Weiterbildung verbessern. Dazu verknüpft das MACE-System die aus verschiedenen Archiven stammenden Informationen anhand zahlreicher Metadaten. Dies geschieht teilweise automatisch, teilweise manuell unter Einbeziehung einschlägiger Communities mittels Web 2.0 orientierter Ansätze.

Mit Hilfe der MACE-Datenbank wird in diesem Projekt versucht, das Thema Baukultur im Land Rheinland-Pfalz zu forcieren und es für Studenten, Architekten, Entscheidungsträger, aber auch für die interessierte Öffentlichkeit zu kommunizieren.

2 EINLEITUNG

Der Begriff der Baukultur ist nicht abschließend gefasst. Die Architektin Louisa Hutton beschreibt Baukultur als „übergreifenden Dialog mit Wirtschaft, Ökologie, Soziologie, Politik und Kunst“ [Hutton 2008:8]. So ist Baukultur als querschnittsorientiertes Sujet zu sehen, das neben Architekten und Planern viele andere Akteure zwingend miteinbeziehen soll und muss. „Baukultur entsteht, wenn Bauaufgaben umfassend gelöst werden: Wenn außer den gestalterischen auch städtebauliche, funktionale, technische, wirtschaftliche, ökologische und soziale Kriterien das Planen und Bauen bestimmen.“ Weiterhin ist in den Leitlinien des Deutschen Städte- und Gemeindebundes verankert: „Baukultur kann nicht von oben verordnet werden. Sie muss als konstruktiver und kreativer Dialogprozess in den Städten und Gemeinden unter Einbeziehung aller Verantwortlichen entwickelt werden“. Weiterhin wird in den Richtlinien konstatiert, dass qualitätsvolle Gestaltung nur dann erreicht werden kann, sofern eine erforderliche Sensibilität für gestalterische Werte bei allen vorhanden ist [Dialog Baukultur RLP 2002]. Baukultur besteht demnach aus folgenden Bestandteilen, die einem ständigen Wechselspiel unterworfen sind: Fest verankert ist die physisch erfassbare Dimension der bebauten Umwelt, die kulturelle Identität einer Gesellschaft und die politische Realität. Alle Faktoren sind zudem vor dem jeweiligen historischen Kontext zu sehen [Baukulturmonitoring 2010].

Die gesellschaftliche und nachhaltige Auseinandersetzung mit dem Thema Baukultur ist allerdings nur dann zu erreichen, wenn das Bewusstsein in der kompletten Gesellschaft verankert ist. Und eben dies ist das Problem: Baukultur wird meist nur vereinzelt von bestimmten interessierten Gruppen wahrgenommen, ein

richtiges Bewusstsein ist im Gegensatz zu anderen europäischen Ländern wie Italien oder Frankreich nicht vorhanden. Die Frage ist: Ist Baukultur messbar nach den Qualitätsmerkmalen wie Gebrauch der Gebäude, ihrer Nachhaltigkeit im sozialen, ökologischen und ökonomischen Sinne, durch die eigentliche Herstellung oder auch nach der Gestalt der Bauten und gebauter Umwelt und deren Integration in den Raum [Streich 2005:341]? Wie können neue Wege gefunden werden, damit gute Architektur und dementsprechend auch eine Auseinandersetzung mit dem Thema Baukultur in der Bevölkerung besser in der Gesellschaft wahrgenommen werden?

3 DAS MACE-PROJEKT

MACE verknüpft Architektur-Repositories mit großen Datenbeständen, um primär für Ausbildungszwecke einen einheitlichen Zugriff auf diese verteilten und heterogenen Datenquellen zu ermöglichen. Inhalte, die vorher nur informierten Benutzergruppen zugänglich waren, können einfacher gefunden werden. Zudem wird der Austausch und die Diskussion durch das Bereitstellen der Informationen untereinander gefördert. Da die zukünftigen Nutzer über ganz Europa verteilt leben und arbeiten, wurden im Projekt auch multikulturelle und multilinguale Aspekte berücksichtigt. MACE wurde von der Europäischen Union im Rahmen des europäischen eContentplus-Programms bis Ende 2009 gefördert und bietet aktuell Zugriff auf über 170.000 Ressourcen aus mehr als 16 verschiedenen Repositories wie zum Beispiel die „UNESCO World Heritage List of Sites“ oder das Architekturportal „Archiplanet“. Für einen detaillierten Überblick über MACE und die technische Realisierung der MACE-Funktionalitäten möchten wir auf [Wolpers et al 2010] verweisen.

Im Gegensatz zu anderen Bestrebungen wie der INSPIRE-Richtlinie, bei der öffentliche Geodaten europaweit für Behörden der besseren Zugänglichkeit wegen normiert werden, will die MACE-Plattform „nur“ einer interessierten Zielgruppe punkthafte, objektbezogene Informationen (den Points of Interests POI) zugänglich machen. Flächenhafte Informationen würden hierbei eher verwirrend und nicht zielgerichtet auf die Endbenutzer wirken. Unabhängig davon ist ein „Geobezug“ über die KML/Google Maps Oberfläche in das Portal integriert, über die Objekte gesucht und auch georeferenziert werden können (vgl. Abschnitt „Map Search“).

3.1 Das MACE-Portal

Das MACE-Portal (http://www.mace-project.eu) bietet eine Vielzahl an Zugangsmöglichkeiten zu den integrierten Inhalten an, die bereits auf der Einstiegsseite (s. Abb. 1) angeboten werden.

Zunächst ist hier die sogenannte Filtered Search zu nennen (s. Abb. 2): Sie erlaubt zum einen eine gängige Stichwortsuche, zum anderen das Filtern nach verschiedenen Dimensionen wie etwa Repository, Sprache oder Klassifikation (beispielsweise die Zuordnung zu einer bestimmten Gebäudetypologie). Entsprechend der erfolgten Auswahl werden nicht nur unmittelbar passende Ergebnisse angezeigt, es erfolgt auch eine automatische Anpassung der Filter, um so die Charakteristika der ausgewählten Menge von Inhalten zu zeigen.

In der angezeigten Ergebnismenge kann der Benutzer entweder unmittelbar zu einem gefundenen Inhalt navigieren, oder zuvor zur entsprechenden MACE-Detailansichtsseite mit weiteren Informationen über die Ressource springen. Ein Beispiel für eine solche Seite ist in Abb. 3 dargestellt. Neben Informationen wie dem Titel und der Beschreibung der Ressource werden auch die formale Klassifikation, assoziierte Kompetenzen, Schlagwörter, Bewertungen und Kommentare sowie die Verortung auf einer Karte angezeigt. Angemeldete Benutzer haben die Möglichkeit, diese Daten selbst zu ergänzen bzw. zu modifizieren.

Eine weitere Zugangsmöglichkeit bietet die Map Search, mit Hilfe derer Benutzer interaktiv einen Kartenausschnitt auswählen können. MACE-Inhalte, die im entsprechenden Ausschnitt verortet wurden, werden sowohl auf der Karte als auch unterhalb (analog zur Filtered Search) angezeigt.

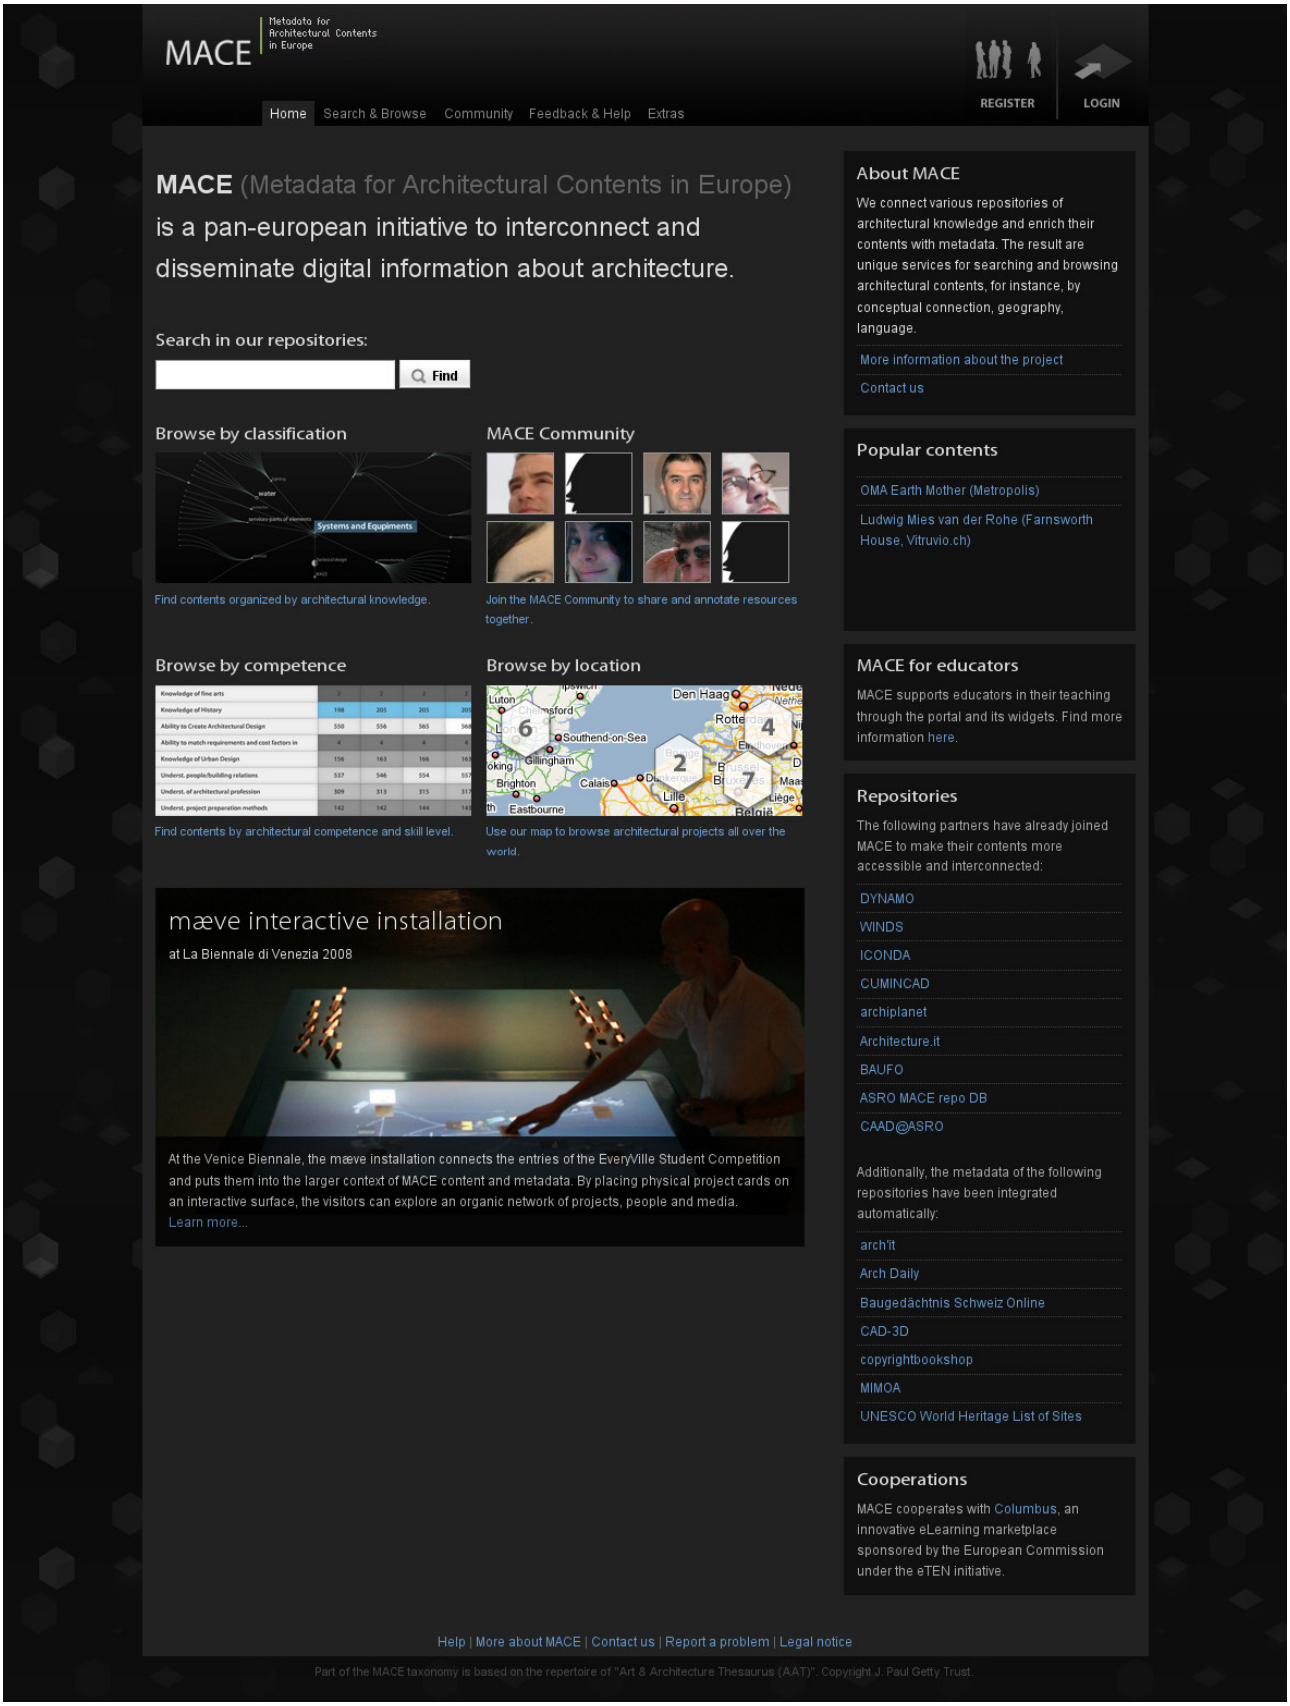

Abb. 1: Einstiegsseite der MACE-Plattform

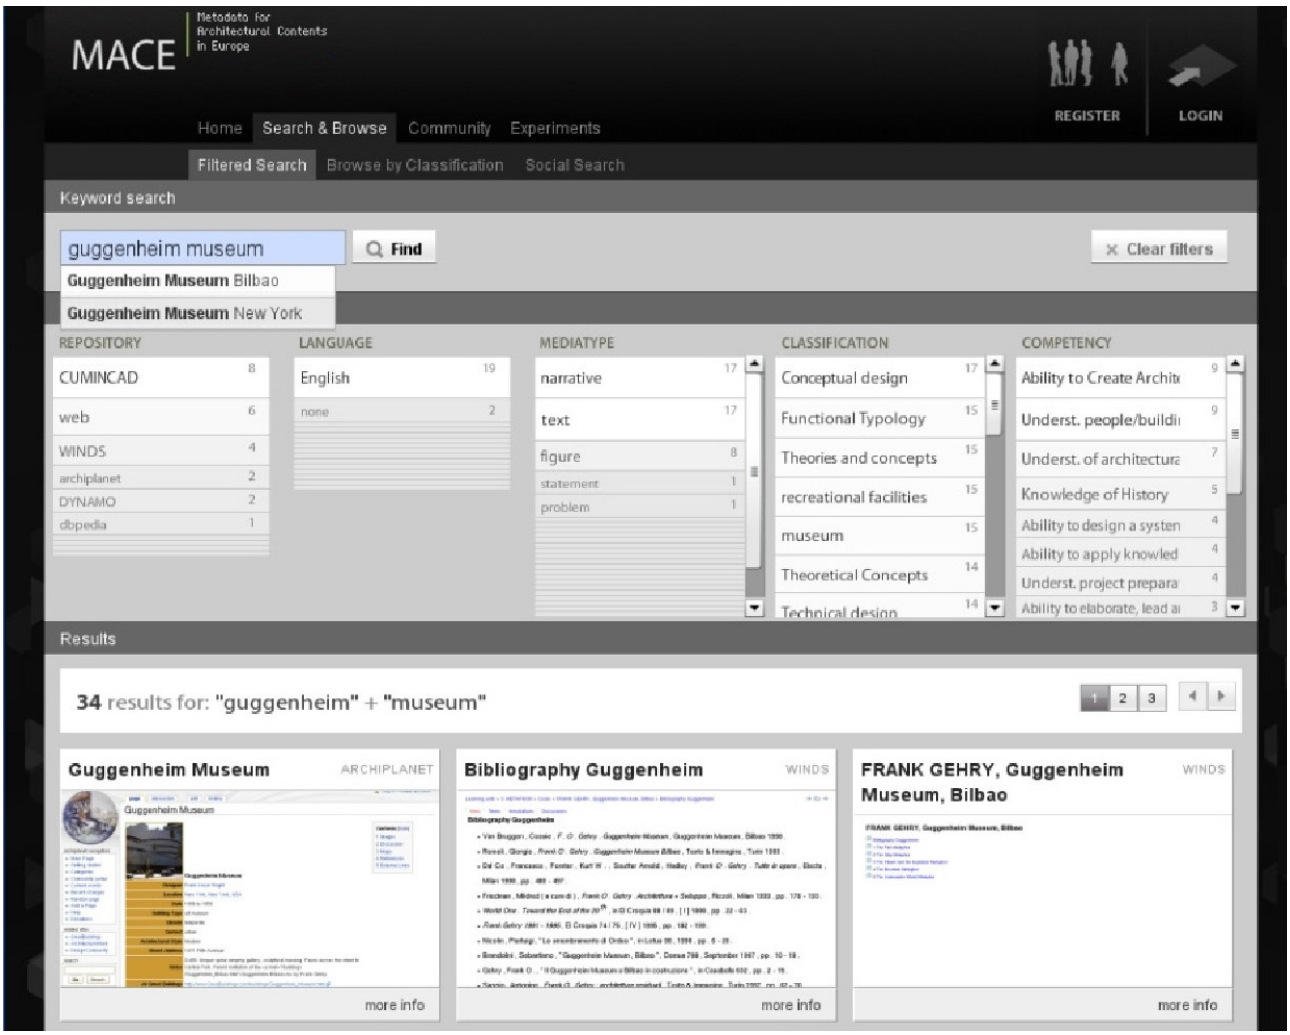

Abb. 2: Filtered Search Ergebnisse zum Thema „Guggenheim Museum“

Auch die in MACE genutzte Architekturtaxonomie mit mehr als 3000 Einträgen kann zum Auffinden von Inhalten genutzt werden. Mit Hilfe des Klassifikationsbrowser (s. Abb. 4) können die Benutzer durch die Taxonomie browsen und sich entsprechende Resultate anzeigen lassen.

3.2 Integration von Inhalten in MACE

MACE integriert eine Vielzahl von Inhalten aus zahlreichen Repositories, ohne diese jedoch aus den betreffenden Systemen zu kopieren. Ein solches Vorgehen würde nicht nur eine nicht unbedeutende Menge an Systemressourcen (z. B: Speicherplatz) verbrauchen, sondern auch komplexe rechtliche Fragen aufwerfen. Stattdessen werden lediglich die Metadaten über die Inhalte integriert. Dies wird realisiert mit Hilfe des OAI-PMH Frameworks [siehe Van de Sompel et al 2004]. Bei dem in MACE benutzten Metadatenformat handelt es sich um eine entsprechend der Spezifika der Architekturdomäne adaptiertes application profile, welches auf dem IEEE LTSC Learning Object Metadata (LOM) Standard basiert [IEEE 2002].

Neben der Integration kompletter Repositories erlaubt MACE zudem das Beitragen von Inhalten seitens normaler Endbenutzer mit Hilfe eines Bookmarklets.[1] Es erlaubt, auf einfache Weise neue Webseiten zu MACE hinzuzufügen und mit entsprechenden Metadaten zu annotieren.

3.3 Systemarchitektur

Das MACE-System ist als eine verteilte, serviceorientierte Architektur (SOA) mit drei Schichten realisiert: Das Frontend mit graphischer Benutzeroberfläche als Client, ein Applikationsserver mit der für die angebotenen Funktionalitäten zuständigen Geschäftslogik sowie der Metadaten-Store als Backend bzw.

[1]Das Bookmarklet kann auf http://portal.mace-project.eu/extras geladen werden

Datenserver. Darüber hinaus sind in MACE sowohl die Systeme ARIADNE[2] als auch ALOE[3] integriert. Während ARIADNE für das Speichern der Metadaten sowie grundsätzliche Geschäftslogik verantwortlich ist, erlaubt ALOE als „Social Backbone“ Beiträge von Endbenutzern und ist für die partizipativen Aspekte und Communityfunktionalitäten zuständig. Für eine genauere Beschreibung der MACE-Architektur und verwendeten Metadaten verweisen wir auf [Wolpers et al 2009].

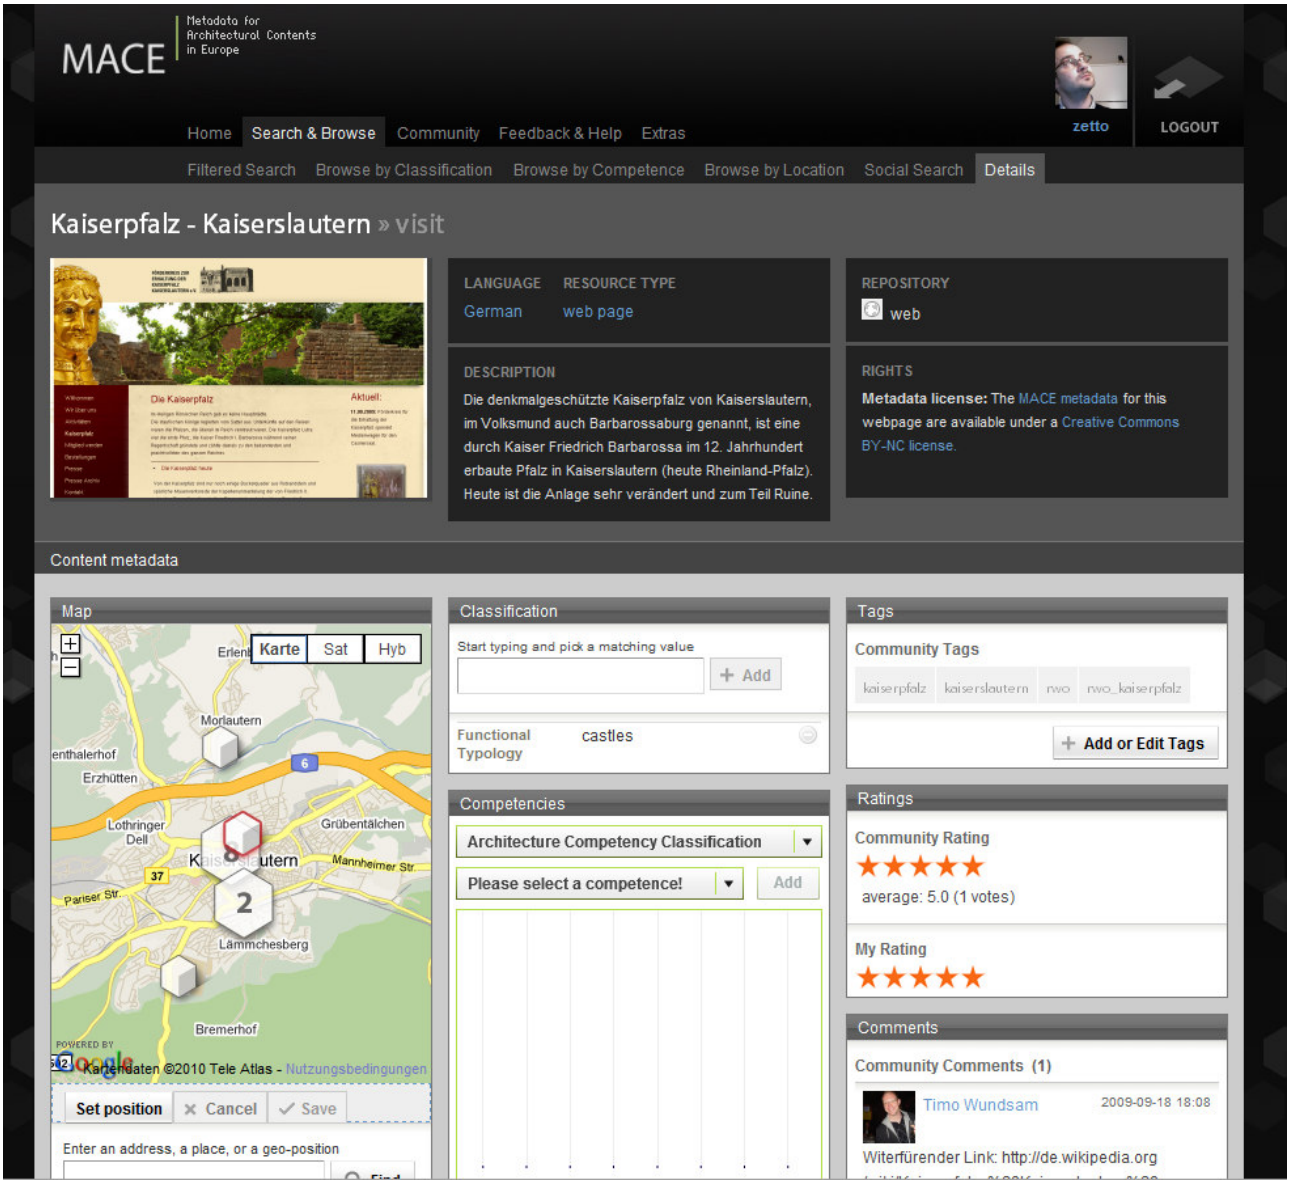

Abb. 3: Detailseite zum Eintrag der historischen Kaiserpfalz in Kaiserslautern, verortet über die Google Maps Oberfläche

4 BAUKULTUR MEETS MACE

Informationen im Internet sind nicht nur durch die Entwicklung mobiler Endgeräte und der entsprechenden Infrastruktur zur Datenübertragung fast jederzeit und überall verfügbar. Schwierig ist aber, den für die eigene Suche richtigen „Filter“ einzusetzen, der bei der immer größer werdenden Informationsflut die qualitativ hochwertigen und vor allem auch relevanten Inhalte findet. Portale können hier eine Lösung sein, jedoch kann das Auffinden der in dem Portal angebotenen Information durch das Phänomen des sogenannten „Deep Webs“ erschwert werden, da die meisten Suchmaschinen diese Inhalte nicht anbieten. Deep Web wird der Teil des Internets bezeichnet, der bei einer Recherche über normale Suchmaschinen nicht auffindbar ist.

Das MACE–Projekt versucht, im „Internet-Dschungel“ eine Hilfestellung zu schaffen, um gezielt und einfach Information über Architektur und damit auch für Baukultur zu erlangen. Hierfür wurden Metadaten aus einer Vielzahl wichtiger Repositories zum Thema Architektur in einer Datenbank zusammengeführt und

[2] http://www.ariadne-eu.org
[3] http://aloe-project.de

über ein Internetportal zentral verfügbar gemacht. Damit wird das Suchen, Finden und Nutzen von gehaltvollen architektonischen Inhalten erleichtert. Zudem versteht sich die MACE-Plattform als innovatives „E-Learning Tools“, das die Bildung bzw. die Weiterbildung architekturinteressierter Nutzer fördern kann. Neben dem Aufbauen eines persönlichen Portfolios ist es jedem Nutzer zudem möglich, sich wie in gängigen Social Communities mit anderen Benutzern zu vernetzen und eigene Inhalte zum Thema Architektur einzuspielen. Des weiteren haben Benutzer die Möglichkeit, Inhalte über eine auf Google Maps basierenden Oberfläche auf einer Karte zu verorten, sie formal zu klassifizieren, und zudem auch zu taggen, zu kommentieren und zu bewerten.

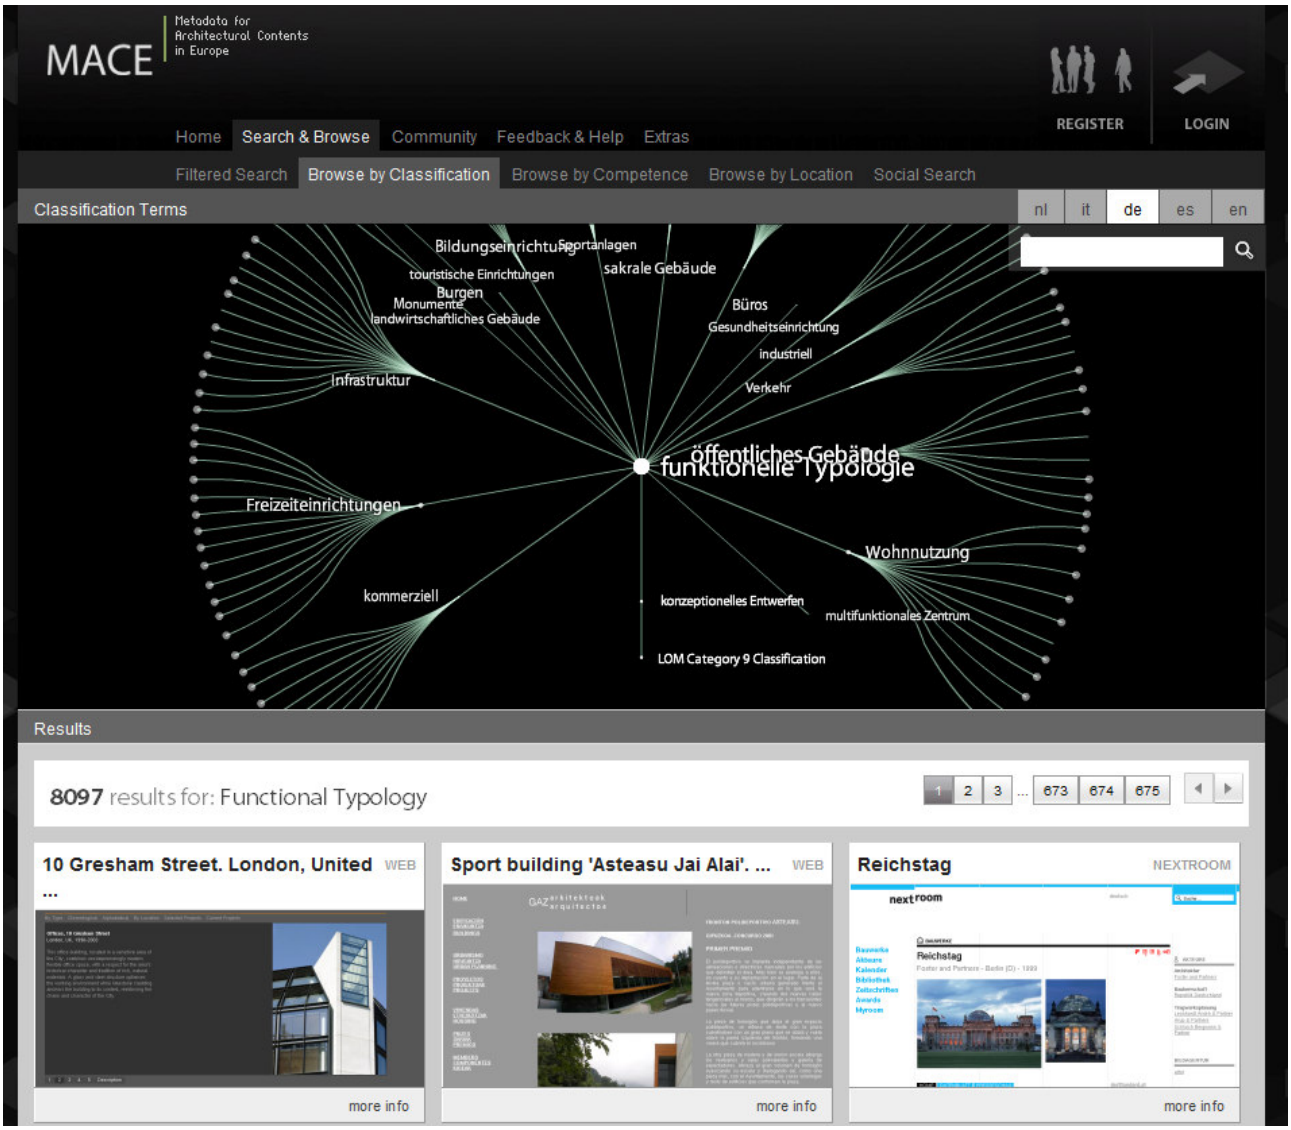

Abb. 4: Die „Browse by Classification“ Suche, in der mit Hilfe einer hyperbolic tree Ansicht MACE-Inhalte basierend auf der MACE-Taxonomie gesucht werden können, hier zum Thema “Öffentliche Gebäude“

Obwohl MACE grundsätzlich auch sogenannte „Real-World-Objects“ (das heißt Informationen und Links zu realen Entitäten wie existierenden bzw. ehemals existierenden Gebäuden oder lebenden bzw. bereits gestorbenen Architekten) unterstützt, mit denen andere Ressourcen dann verknüpft werden können. Momentan ist es für Endbenutzer noch nicht möglich, solche Objekte selbst einzuspielen. Der Fokus in der Datenbank liegt (noch) auf Dokumenten zum Thema Bauen. Auffällig bei der Betrachtung der von Benutzern eingespielten Inhalte ist zudem, dass die Region Rheinland-Pfalz und den dem angrenzenden SAAR-LOR-LUX Bereich eher als „terra incognita“ auf der Google Maps Oberfläche geführt wird.

Die Idee ist nun, Daten aus Rheinland-Pfalz und der SAAR-LOR-LUX Region zu sammeln, in MACE einzuspielen und so einen Beitrag zum Thema Baukultur zu liefern. Dabei soll auf bestehende Informationen wie zum Beispiel die Homepage der AchitekTouren, UNESCO-World Heritage, Zeitschriften, Foto-Communities etc. zurückgegriffen werden. Wichtig sind hierbei sowohl die Klassifizierung als auch die

Georeferenzierung der Objekte über die Google Maps Oberfläche. Neben der Einspeisung der Daten ist die kritische Auseinandersetzung mit dem MACE-Portal ein zentraler Punkt des Projektes, d.h. es sollen Ideen und Vorschläge entwickelt werden, wie das Thema in Hinblick auf Baukultur, Tourismus, Routing, Webdienste noch besser vermittelbar wäre und über welche Anreize es gelingen kann, Benutzerpartizipation zu fördern.

Vor diesem Hintergrund steht das hier vorgestellte Projekt, in dem eine Nutzergruppe aus Kaiserslautern baukulturell interessante Objekte in der Region verortet, klassifiziert und somit einen wertvollen Beitrag Verbesserung der Wahrnehmung von Baukultur im Land einrichten kann. Zudem wirft die Arbeit und das zur Verfügung stellen von Inhalten die Frage auf, ob damit es zu einem (besseren) Diskurs über das Thema Baukultur kommen kann.

5 METHODE

Da das Bearbeiten der Fragestellung „Baukultur“ mit der MACE-Plattform zu einem sehr späten Zeitpunkt der Entwicklung des Portals erfolgte, lag neben der eigentlichen Bearbeitung des Themas auch eine kritische Reflexion der sogenannten Usability . Das Hauptziel war, dass baukulturell interessante Inhalte in die MACE-Datenbank unter Zuhilfenahme von Web Ressourcen und des eigens entwickelten MACE-Bookmarklets eingepflegt werden. Die Inhalte sollten anhand von selbst gewählten Auswahlkriterien wie zum Beispiel Einfamilienhausarchitektur, „Green Building“ oder kulturelles Erbe in der MACE-Datenbank formal kategorisiert und georeferenziert werden. Um trotz der Beschränkungen seitens MACE Real-World-Objects einspielen zu können und zugehörige Informationen zu verlinken, wurden ersatzweise Wikipedia-Seiten herangezogen und Tagging-Konventionen genutzt, um die zugehörigen Objekte zusammenzufassen.. Der Vorteil liegt darin, dass jeder „Tag“ ein Attribut für weitere Portalfunktionen oder GIS-Anwendungen sein kann.

Neben der inhaltlichen Auseinandersetzung lag die kritische Reflexion zur Benutzerfreundlichkeit des MACE-Portals allgemein im Zentrum der Betrachtung. Zusätzlich sollten Überlegungen getätigt werden, inwieweit das Portal eventuell noch modifiziert werden müsste, um das Thema Baukultur noch besser, transparenter und schneller den Benutzergruppen näher zu bringen.

6 ERGEBNISSE

Insgesamt wurden in der Testphase 578 Einträge zum Thema Baukultur in Rheinland-Pfalz getätigt, zudem wurden die Objekte alle georeferenziert und mit 3543 Tags versehen. Hauptthemen bei der Bearbeitung waren Burgen-Schlösser-Altertümer, Wein(Kultur), Kirchen, Green Buildings, Stadien und der Umgang mit Zeugnissen der Industriekultur im Saarland.

7 FAZIT

Das MACE-Portal bietet bereits umfangreiche Möglichkeiten, um als Datenbank für Baukultur im regionalen Einzugsgebiet zu fungieren. Mit den vorhandenen Funktionalitäten ist ein großes Potenzial vorhanden, das weiter ausgebaut und ausgeschöpft werden sollte.

Eine denkbare Möglichkeit, dieses Potenzial weiter zu entwickeln, ist die mobile Umsetzung des Portals, so dass es möglich ist, auch unterwegs bereits in der Datenbank befindliche Informationen abzurufen oder sogar Informationen zu Gebäuden bzw. Bauten neu aufzunehmen und zu verlinken. Dabei müsste die Neuaufnahme in weiten Teilen automatisiert werden, denkbar ist hierbei, den technischen Stand der Smartphones sinnvoll zu nutzen, indem das GPS-Modul automatisiert die Position ermittelt und in die Datenbank einträgt. Exemplarisch wurden die MACE-Inhalte seitens der Open Universiteit Nederland von Dr. Stefaan Ternier bereits in die Augmented Reality Applikationen ALOQA[4] und LAYAR[5] integriert. MACE-Inhalte können somit abhängig vom aktuellen Standort und der Blickrichtung des Benutzers angezeigt werden.

Doch nicht nur der technisch-mediale Weg kann zur Öffentlichkeitsarbeit genutzt werden. Es sollten auch Fachzeitschriften mit Werbung versehen, Publikationen über die Nutzung des Portals veröffentlicht und Aushänge an Universitäten und Fachhochschulen gemacht werden, die auf die Existenz eines solchen Portals

[4] http://www.aloqa.com/
[5] http://layar.com/

hinweisen. Dies kann weiteres Interesse für das Projekt wecken und auf diesem Wege eine höhere Teilnahmequote fördern.

Abb. 5: TagCloud der eingespielten Inhalte zum Thema Baukultur in RLP, visualisiert mit http://wordle.net

Eine weitere Nutzung des Portals ist dahin gehend denkbar, dass Städte dieses zur Öffentlichkeitsarbeit nutzen, indem sie interessante Bauwerke darauf vorstellen und sich dadurch repräsentieren, wie es beispielsweise schon in der Stadt Osnabrück geschehen ist: Es wurden historische Gebäude, der Kultur- und Landschaftspark, alle Kirchen sowie die vor Ort ansässigen Museen mit einbezogen, die dem Nutzer einen Einblick in den historischen Stadtkern geben sollen und die Stadt als touristisches Reiseziel interessant machen. Hier ist ein Ballungsraum von historischen Gebäuden in der Kernstadt vorzufinden.

Durch Anhängen von KML - Dateien an die einzelnen Objekte wäre durchaus ein Routing denkbar, das Touristen durch die Stadt entlang der einzelnen Sehenswürdigkeiten führt. Des Weiteren wäre für geschichtsinteressierte Touristen denkbar, die Google Earth Darstellung mit historischen Karten zu hinterlegen. So wäre z.B. bei Interessenten, die ein Mobiltelefon mit GPS – Empfänger nutzen die Möglichkeit gegeben, herauszufinden, was sich in früheren Zeiten an den entsprechenden Orten und Plätzen, auf denen er sich bewegt, befand. Hierdurch wäre auch eine weiterführende Verknüpfung der einzelnen Objekte untereinander in der Datenbank von MACE denkbar.

Die Community steht für jeden Architekturinteressierten offen: Probieren Sie es aus! http://portal.mace-project.eu

8 DANKSAGUNG

An dieser Stelle möchten wir uns bei den Probanden, die an diesem Projekt teilgenommen haben bedanken. Trotz einiger technischer Schwierigkeiten sind hervorragende Ergebnisse heraus gekommen. Im einzelnen sind dies: Benjamin Allbach, Nadja Bautz, Ricardo Sousa Carvalho, Susanne Franz, Alexander Jung, Alexander Masser, Jasmin Ohnesorg, Stephanie Petry, Andrea Picht, Marcus Reeg, Rebecca Trautmann, Willi Wendt, Timo Wundsam und Eike Zender. Vielen Dank für Euer Engagement!

Bikabilty In Metropolitan Lagos: A Conceptualization of Eco Friendly Transportation Alternative

Tunji Adejumo

(Tunji Adejumo, Department of Urban and Regional Planning Faculty of Environmental Sciences, University of Lagos, Akoka. Lagos; tunjiadejumo@gmail.com)

1 ABSTRACT

Mobility induced city air pollution is evident in the metropolis where governments annual budgets emphasized road transportation and car ownership at the detriment of ferry, rapid and light rail transit systems. Alternative mobility frame work advocates for circulatory facilities including sidewalks, walkways, paths and bike lanes. These facilities minimally impact cityscape, rely on renewable energy, use less urban space, reduce traffic congestion, improve physical fitness and are cheaper. This paper explores conceptual framework for bicycle as an eco friendly transportation system in Lagos.

The study identified the fear of accident and the absence of 'changing rooms' in most public destinations as major constrains to the acceptance of bicycle as transportation mode. The later reason is due to the fact that Lagos is a hot and humid tropical city. Leisure cycling was however accepted as a recreational undertaking. An off road bicycle route system was conceptualized using satellite imagery, geographic information system and AutoCAD as design tools and Lagos State physical planning development control standards. 52 kilometers 'off road' bicycle route case study between Ikeja as point of departure and Bariga/Yaba as destination was undertaken. The route falls within setback of Ogbe and Iyaalaro rivers flood plain refered to as tertiary sytem 1 and 2 and railway setback. It is apparent that acceptability of bicycle as effective transportation mode in the city will be triggered by sustained interest in leisure cycling. The Paper recommends that LAMATA (Lagos Metropolitan Area Transport Authority) should embark on categorization of bicycle policies as general policies, facility policies and issue-based policies that will provide a practical guide to sustainable non-motorized transportation mode.

2 INTRODUCTION

The realization that scientific urbanism is unable to manage the waste products of the technology that define it continue to attract discussions on the health of the city. The philosophy of architectural modernism treats cities as architectural objects on regional landscapes crisscrossed by highly geometric streets that sustain automobile mode of transportation. The shortcomings of this technologically inspired urban concept is the inability to manage the wastes from supporting resources especially emission of hazardous gases from thousands of automobiles that daily load the streets. The destructive impact of gaseous emissions from fossil fuel driven engines especially nitrogen dioxide, voltaic organic compounds and carbon dioxide is worrisome. Nicholls (2004) referred to this destructive effect as degradation of life support system since they play major role in the depletion of ozone layer. The much celebrated modernism school of urban design collapsed under the weight of the very transportation technology that set it up. The desire to solve transportation induced urban pollution pushed mobility in urban centers to sustainable paradigm.

Mobility induced city air pollution is evident in metropolitan Lagos where governments annual budgets emphasized road transportation and car ownership at the detriment of ferry, rapid and light rail transit systems. About 40% of all new vehicle registration in Nigeria are in Lagos and accounts for 40% of the total national premium motor spirit consumption (Olowoporoku, 2007). Over 27,500 automobiles excluding commercial motor cycles load the streets on daily basis (Loricamp, 2007). 95% of these vehicles were manufactured over ten years ago without catalytical converters to minimize noxious effluents. Vehicular density is estimated at 220 vehicles per kilometer compare to national average of 1.1 vehicles per kilometer (LSG, 2006). About 20 years ago commercial motorcycle emerged to complete auto based transportation mode. Arbirage (1997) analysis of the city traffic showed an earlier domination by bus, 53%; private cars, 23.5%; taxi 18,5%; and commercial motorcycle 5% bringing to reality the continuous reliance on automobile transportation mode. Recent studies revealed that the metropolis has daily passenger trips record of about 6 million people (LSG,2006). 75 % of these trips are by bus based public transportation system; 24% cars and a negligible 1% rail and ferry service. None of these studies highlighted modal split in the metropolis. The problem of land transportation is not restricted to congestion but also deteriorating infrastructures, high consumption of non renewable hydrocarbon energy and polluted air space.

Air quality of the metropolis is a reflection of long hours of traffic congestion (Loricamp, 2007). There is no systematic measurement of the air quality in Lagos; however a few studies have reported measurements of green house gases especially carbon monoxide and volatile organic compounds. Arbritage (1997) attributed 11.37 tons of volatile organic compounds per year; 175.4 tons of carbon monoxide per year; 297 tons of nitrous oxide per year,; and 32 tons of sulphur dioxide per year to motorized road transportation mode. These gaseous effluents did not include emissions from generators as alternative energy source at both residential and industrial estates. According to LASEPA (2001) carbon monoxide measurement at Oba Akinjobi Way, Arch Bishop Vinning Memorial Church, Immigration Junction and Lagos Country Club/ Joel Ogunnaike Street at Ikeja was 63ppm, 27ppm, 67ppm and 72ppm respectively.

Mitigating measures for climate change, demand reduction of carbon dioxide and other green house gases emissions by 60-80% (WWF 2008),. This calls for the development of new energy saving transportation strategies. Sustainable transportation planning as a remediation tool for local air quality problems respect renewable energy sources. Within the context of sustainable urban design, non motorized transportation facilities give priority to walkways, sidewalks, public paths, trails, bike lanes and generous arterial road shoulders. These facilities accommodate a diverse range of users including people standing, sitting, children playing games, vendors, walkers and physically challenged individuals. Transportation modes supported by these facilities include wheel chairs, joggers, skating boards and bicycles. Bicycling minimally impact cityscape, rely on renewable energy, use less urban space, reduces traffic congestion, and improves physical fitness. This paper explores conceptual framework for bicycle as an eco friendly transportation system in Lagos metropolis.

Metropolitan Lagos developed on low lying sand barrier-lagoon coastal geomorphology at an average elevation of 3 meters above sea level. It is characterized by loose sedimentary sandy soil formation that supports fragmented fragile riparian landscape delineated by wetlands. The metropolis is framed by longitudes 2 0 42/ E and 30 22/ E of the Greenwich Meridian and latitudes 60 22/ N and 60 42/ N of the equator. Littoral climatic variables prevail throughout the year. Ikeja and Shomolu local government areas of northern metropolitan area are chosen for the case study. The study area is an agglomeration of 15 communities with a total population of about 955,000 (nine hundred and fifty five thousand) people.

3 SUSTAINABLE TRANSPORTATION PRINCIPLES

Sustainable transportation play dominant role in the transformation of existing urban centers into healthy ecological cities. Such mobility framework does not endanger public health but accommodate transportation modes that depend renewable energy resources. Sustainable city transportation network is an urban design concept that emphasis the importance of reducing the number of pollution generating fossil fuel driven automobiles. This study is underpinned by ecological design concept and Community Cycling Accessibility Initiative (CCAI) philosophy. Ecological urban design concept is the incorporation of the knowledge of how nature operates into city process. When human settlements take advantage of natural processes that makes the ecosystem functional then a healthy urban ecosystem is borne. This is what Register (1992) referred to as ‘eco city’. It is a city conceptualized on minimal developmental impact; inhabited by people committed to efficient energy, water and food consumption; and pay much attention to generated wastes especially gaseous, heat and liquid emissions. Ecologically designed human settlement takes advantage of available energy sources and demands that open spaces, streets and transportation medium meet high energy efficiency standards (Downton, 2003).

Ecocity strives for minimum use of automobiles as transportation mode. It promotes low energy consumption automobiles, zero-emission vehicles including electric vehicle and integrated public mass transportation strategy that are technology driven. Ecocity transportation measure at this level may not be feasible as a result of shortage of man power and high technological cost. Shifting the attention from automobile transportation must evolve a policy underpinned by the philosophy of ‘city for public mass transit system, pedestrians, and cyclist. Streets of such cities must then be conceived to be pedestrian friendly. Community Cycling Accessibility Initiative (Vanek and Spindler, 1999). is one of the several conceptual frameworks for non motorized transportation mode.

The core mission of Community Cycling Accessibility Initiative (CCAI) is to encourage cycling especially transport oriented cycling that reduces car trips through improvement of existing cycling infrastructure and construction of new ones. CCAI allows for combining ‘both leisure and non leisure cycling into a single

campaign to provide safe cycling routes where people can travel to and from amenities they need' (Vanek and Spindler, 1999). Amenities refer to active nodal spaces including bus terminals, schools shopping complex, offices and commercial establishments. The argument in favour of CCAI is that government should invest in cycling infrastructure just as road network is currently funded. CCAI advocated four criteria to be used in identifying most suitable locations for bicycle infrastructure including sufficient population density, predominant use of automobiles in the current situation, sufficient space for adding new infrastructure with community interest in mind and high rate of bicycle ownership.

While metropolitan Lagos satisfies the first three factors, ownership of bicycle is very low. So insignificant is the place of cycling as transportation mode in the city that recent transportation studies including Arbirage (1997), LSG (2006), Loricamp (2007), Olowoporoku (2007) and Rom and Phoenix (2007) did not consider it in their report. Rather emphasis was on fresh public mass transit policies. The solution to automobile based traffic congestion in cities demands a deliberate change in transportation policies that will reduce automobile traffic. Such policies must respect the role of non motorized and car free planning. Non motorized facilities include walkways, sidewalks, crosswalks, paths, pedestrianized streets, pedestrian plazas, bike lanes and highway shoulders. The starting point is to identify the current modal split of Lagos commuting population. Modal split refers to the form of transportation a person chooses, including walking, bicycling, public transit, and driving cars. The aim of this study is to increase the percentage of people who will choose to bicycle rather than travel by automobile in the metropolis. This is because every motor vehicle trip traveled that is eliminated represents a quantifiable reduction in air pollution and traffic.

3.1 METHODOLOGY

The first phase of this study recognizes participatory research as a viable physical planning tool for people oriented transportation program. Relevant primary data was obtained through a combination of three descriptive survey instruments including questionnaire, semi structured interviews and personal observation. Administered questionnaires took into consideration age group and focused on the choice of transportation options and acceptability of bicycle as a recreation and transportation mode. The structured open-ended interview was drawn to collect information from the public about their views on the current transportation mode and expectations on cycling in the city. The primary data were analyzed to understand feasible options that will accommodate new bicycle infrastructure within the metropolitan setting. The later recognizes previous research works and planning reports as authentic secondary source of information. Desk top studies took into consideration Lagos State Metropolitan Plan (LSD 1985); Lagos State Review Regional Master Plan (Ashinyanbi 2005); Ikeja Model City Plan (IMCP 2008). Desk top studies focused on the compliance of the study area to positive bicycle facilities physical planning criteria meant to enhance livability in the metropolis. This constitutes the second phase of the study. Satellite imagery and digitized plans were analyzed to authenticate and update the physical state of the study area through direct observation. Updated base map was subjected to ecological city planning principles to proactively assess the readiness of the study area to accommodate eco friendly bicycle infrastructure.

4 PUBLIC PARTICIPATION IN CYCLING INFRASTRUCTURE

Engaging the public in the planning process is critical to the success of any transportation mode. The study revealed that 55% Lagos commuting population show preference for public mass transit followed by privately owned cars (35%). Figure 1 Shows that 8% will trek while the remaining 2% opt for cycling. Public mass transit refers to mini shuttle bus and the recently introduced Bus Rapid Transit (BRT) system with exclusive road lanes earmarked along major high ways in the metropolis. This has brought some level of relief to few commuters who hitherto rely on private cars. Figure 2 probes the present low interest level of bicycling in a metropolis that once relied heavily on cycling as transportation mode by the middle of last century. The fear of accident on the congested streetscape (57%); lack of public changing facilities at various destinations (20%); increasing crime rate and poor security (16%); and the stigma of attaching poverty to bicycling lower economic class at rural Lagos (7%) were reseasons given for low interest in cycling. The latter is the legacy of crude oil economic illusion left behind by long years of military ruler ship and the flamboyant life style of extremely corrupt political elites. 71% of the respondents agreed that if the fear of accident on the busy roads and security of the cyclists are guaranteed then leisure cycling will be considered while the remaining 29% hinged their participation in non leisure cycling on availability of changing facilities at schools and government office complexes. The interest in leisure cycling is connected with the

dearth of public spaces in the city. Ashinyanbi (2005) noted that the ratio of planned hectare of open space per population in metropolitan Lagos dropped to an all time low figures of 90,000 people per hectare which was far from international standard of 300 per planned hectare. Any recreational infrastructure in the metropolis will boost the much needed leisure facilities. Leisure cycling is compatible with non motorized and car free planning philosophy. Nonmotorized modes are either developed along roadways or off road trails along urban natural corridors including parks and urban wilds.

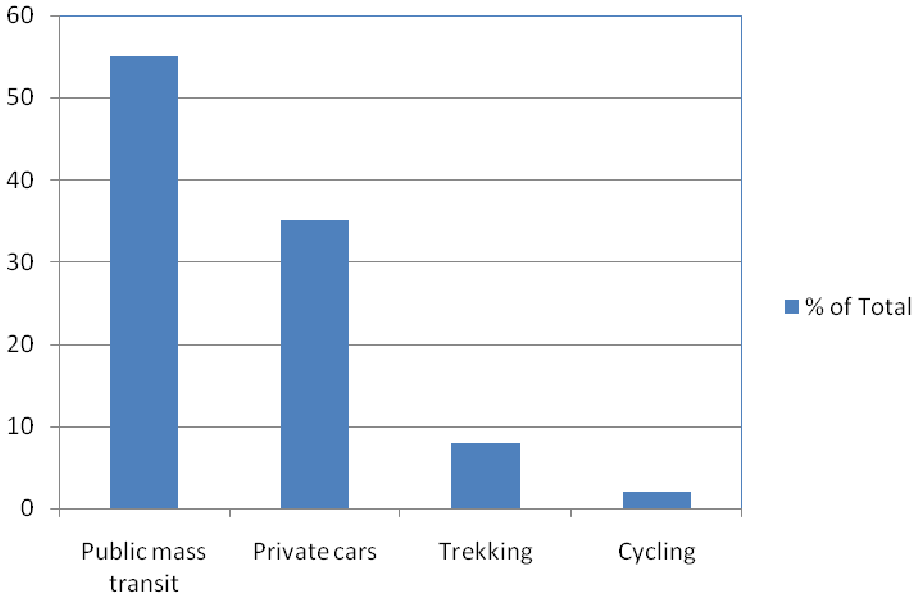

Figure 1. Lagos Commuters Transportation Prefernce

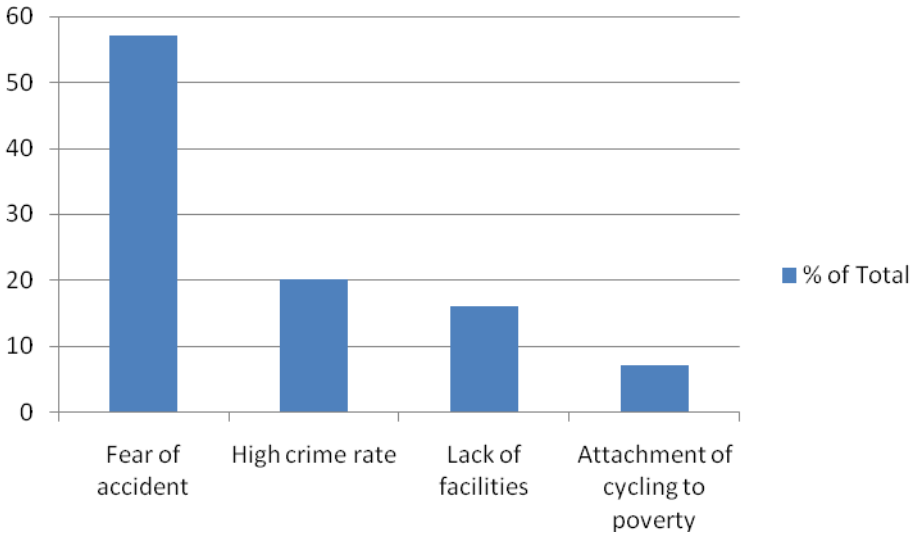

Figure 2 Present Low Interest In Cycling

5 LOCAL BICYCLE FRIENDLY AGENDA

Healing the urban landscape must take a holistic look at ecocity principles that can be accommodated within the present sociopolitical, economic, technological and human resources capability of the state government. Local sustainable transportation infrastructure planning model that can mitigate climate change impacts will be situated within Kenworthy (2006) conceptual model to enhance the compliance of existing cities to eco city principles. Kenworthy (2006) 'sustainable urban form and transport factors' reiterates the importance of compact, mixed-use urban form that uses land efficiently and protects the natural environment, biodiversity and food-producing areas. It is a high density development city concept that does not accommodate sprawling but have ample land area devoted to green infrastructure. This measure is easily and economically

achievable in new towns, new housing complexes and industrial estates. Currently Lagos streetscape is not planned to support non motorized transportation mode especially on-road bicycle route system. The existing streets are conceptualized as thoroughfares framed by silted open storm drainage channels with irregular concrete fence background along the beacon line. Introduction of energy saving transportation mode in already built up and highly populated metropolis demands high financial capital driven urban revitalization projects which the current economy may not support.

5.1 OFF ROAD NON MOTORIZED MODE - SUITABLE ROUTE

Yamakawa (1999) identified four categories of bicycle roads namely separate bicycle alone route, bicycle and pedestrian routes running side by side, on road bicycle track and on road bicycle and pedestrian track separated from vehicular lane. While the first two are ideal for off road route system the last two are part of existing streets and road right of way. Rehabilitating existing Lagos road to accommodate either of on road bicycle route system will be financially involving. Besides, the interest of the people at this point in time, is not on bicycle as a transportation mode but leisure cycling. As a starting point introducing off road non-motorized route system made up of walkway and bicycle on leisure platform may trigger the interest of the people in the nearest future. Possibility of safe off road bicycle route system is demonstrated for Ikeja and Shomolu local government areas in northern metropolitan area of Lagos (Figure 3). As noted by Ashinyanbi (2005), there is no planned metropolitan public park system. More compatible green land uses are the numerous wet lands that define the various communities and unplanned waterfront area. Drainage basins and flood plains separate the various townships and cities that make up the metropolis. There are six major natural drainage basins, at a total length of 112.22 kilometers (Table 3). These drainage basins are the city's tertiary drainage systems and are designated system 1 to 6. The northern metropolis is drained by systems 1 and 2. The most prominent is "system one" also known as 'Iyalaro' River that drains lower Ogba, Ikeja, Opebi, Ojota, Anthony and Ifako- Bariga townships into Lagos lagoon. System 2 drains Akoka, Bariga, Gbagada townships. These drainage system and other water bodies are secured by developmental control legal setbacks including 150 meters from the ocean, 75 meters from lagoon shoreline, 60 meters from rivers and 15 meters from canals (LSG1986)

SYSTEM	LENGTH
System 1	18.93km
System 2	7.0km
System 3	4.7km
System 4	7.09km
System 5	21.0km
System 6	53.5km

Fig. 3: Major Drainage Channels in Lagos Metropolis Length and Area (Source: World Bank Assisted Lagos Drainage and Sanitation Project 1998)

Subjecting the identified natural drainages and railway right of way to modified CCAI principle provides the opportunity for safe off road non motorized transportation mode made up of bicycle route system and walkways. CCAI allows for combining both leisure and non leisure cycling as unit to provide safe cycling routes where people can travel to and from important nodal spaces (Vanek and Spindler 1999). The first phase of CCAI principle is aligning safe cycle route through identified corridor with minimal obstructions at busy roads and other thoroughfares in the city. Bicycle route alignment along the natural basins took into consideration the upper terrace of the flood plain free from the peak annual flow of the rivers. This case study allows for 18 kilometers off road bicycle route along the flood plain upper terrace of 'System One' from Adeniyi Jones Ikeja township to Oworonsoki without crossing the highways. The alignment is conceptualized to run parallel to Iyaalaro River and using the existing under bridge pedestrian set back to escape crossing the two highways. A tributary of Iyaalaro River drains Pedro Township and constitutes system 1A and covers 4 kilometers. The cycle route alignment follows the 15 meters canal setback to connect System 2A. While system one has an average width of 100 meters, system two has been narrowed by developmental activities and now functions as manmade canal. The average width on each side of the canal is 15 meters being the setback prescribed for development control. The proposed off road bicycle route is set within the 15 meters set back. It emanates from University of Lagos and aligned along Ogbe River

canal (System 2A) which drains Shomolu and Gbagada townships. Linking System 1A and system 2A involves crossing 10 residential streets. These intersections must be addressed through traffic management mechanism.

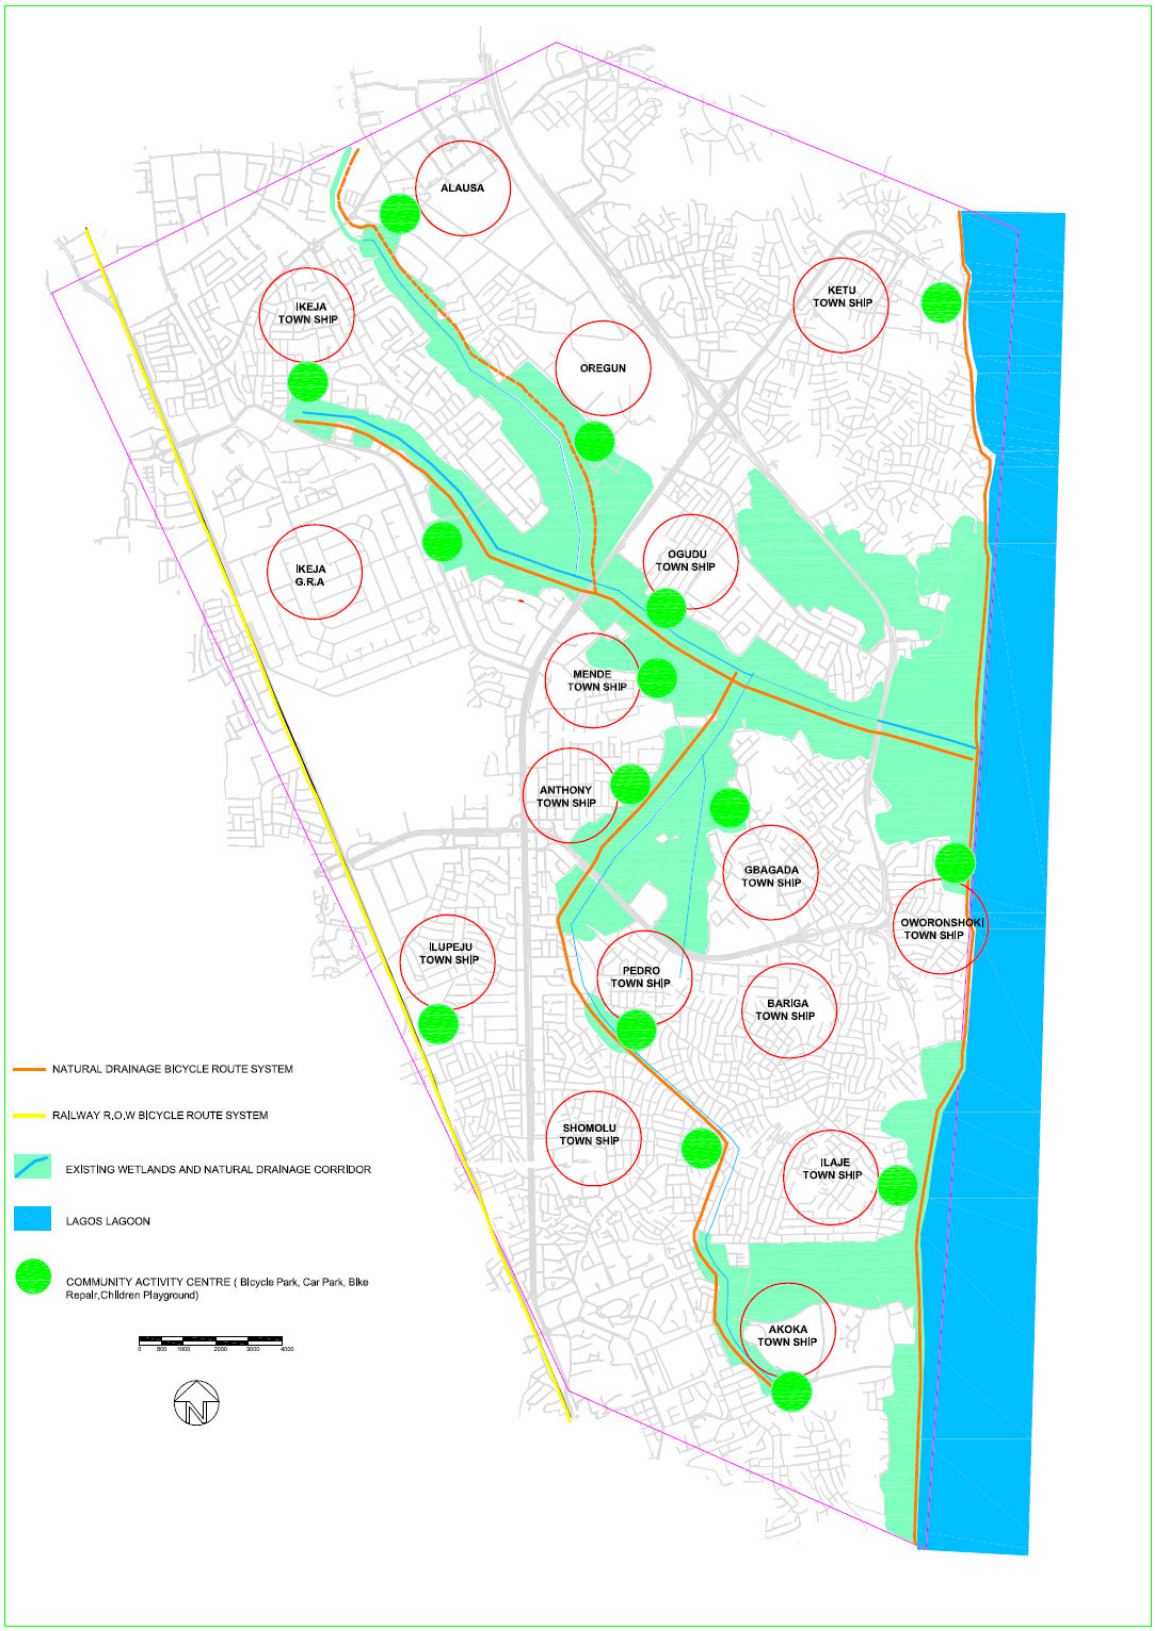

Figure 3 Possible Off Road Bicycle Route System

The 30 kilometers Nigeria Railway Corporation dual carriage rail line stretches from Iddo terminus in the south to Agege in the north. The minimum set back allowed between a building and railway line is 21 meters (LSG 1986). Aligning a three meter bicycle/ pedestrian route within the setback provide a vehicle free lane

for cyclists. This off road concept along the natural drainage and railway set back recognize other important elements including bicycle parks at adjacent communities; car parks; bicycle repair points and practicing tracks. In the absence of metropolitan park system, introduction of minor adventurous play ground might become the nucleus for adjoining communities to have a park. This leisure cycling concept. becomes a trigger for livable outdoor environment in hot and humid tropical city in dire need recreation centers

6 CONCLUSION AND RECOMENDATIONS

Bicycling was an important transportation mode in Lagos State until the advent of crude oil economy in 1970s. Unfortunately the rate at which people are biking to work decreased drastically in many urban communities within the metropolis. During this same period, life expectancy dropped while obesity increased, contributing to health problems in the city. These two trends are related, and demand the creation of livable built environment that accommodates bicycling as a key element to rectify the critical issues. This is a major challenge in the face of high costs of health care delivery, energy crises and reliance on vehicular transportation mode. The way forward for bicycle as a transportation mode and leisure facility resides in its immediate recognition. The recognition must commence from the introduction of non-motorized transport mode policy. Such policy should benefit from internationally acclaimed and tested 4Es bicycle planning philosophy namely engineering, education, enforcement and encouragement. Since successful bicycling programs involve education, engineering and enforcement efforts, diverse cross section of government ministries, agencies and parastatals must contribute to required policies. Prominent ministries include physical planning, environment, education, health and transport. While ministry of transport is expected to drive bicycle policy as an energy saving and eco friendly transportation mode, ministries of sport and health will jointly evolve bicycle related sports and recreation policies.

The stated hindrances to non leisure biking by residents including fear of accidents, insecurity and lack of changing facilities in destinations is not restricted to Nigeria. Such problems have been experienced in other cities and appropriate tested solutions that may be useful in Lagos devised. What is really needed at this point in time is a political will to accept non-motorized transport mode as an effective eco friendly alternative to mitigate negative impacts of hydrocarbon driven automobile mode. As noted by Yamakawa (1999) bicycle should be seen as a transport mode ideal for short distances to identified destinations within the city. Specific areas of focus to enhance the goal of an eco friendly bicycle as transportation mode in Lagos are as follows:

- Secure the various drainage basins and canals through strict application of development control instrument. This will checkmate encroachment by land speculator.
- Relate properly with railway and other Federal Government agencies that hold the potential right of ways in trust for the people.
- Consider the the incorporation of Lagos Traffic Operatives along the routes. The officers must be made to relate to security agents to allay the fears banditry along the lanes.
- Government transportation agency especially LAMATA (Lagos Metropolitan Area Transport Authority) should embark on categorization of bicycle policies as general policies, facility policies and issue-based policies that will provide a practical guide.

The later, issue based policies, are the most important at this point in time. Included are policies on sidewalks, crossings, trails in green areas, bicycle parking and changing facilitities at civic buildings and public nodal spaces . Health and fitness, energy conservation, air quality, and safety must be given adequate priority to secure the confidence of the people bicycle riding.

Chongqing at Crossroads: How Urban Planning and Infrastructure can Support Sustainable Industries.

Debra Lam, Andrea Fernandez

(Debra Lam, Senior Policy Consultant, Arup, debra.lam@arup.com)
(Andrea Fernandez, Associate, Arup, andrea.fernandez@arup.com)

1 ABSTRACT

Chongqing, the "Furnace of China" makes a potent case against the consequences of the traditional model of industrial growth left unchecked. Environmental degradation and pollution threaten not only its residents' quality of life, but also its future as an economically competitive municipality. Chongqing still possesses abundant resources and low-cost labour, however. But to continue to remain viable, Chongqing needs to apply a sustainable, integrated development model that addresses local context in urban planning, infrastructure resource efficiency, and especially industrial symbiosis. The municipality's economic vitality demands greater industry collaboration and leadership. Chongqing is at a crossroads. This study underscores the need for action and provides forward-thinking recommendations that will ensure Chongqing continues to thrive and set the model in western China as a centre for sustainable industries.

2 CHONGQING AT CROSSROADS

Chongqing is currently the only major municipality in western China and is a leading center of foreign investment and manufacturing. It has benefited from government policies, such as the Grand Western Development strategy and various Five Year Plans, building a large industrial and agricultural base centered on domestic consumption.

However, Chongqing still lags behind Beijing and coastal cities such as Shanghai and Guangzhou. It also faces increasing competition from its western counterparts, Chengdu and Xi'an. Its rating in the United Nations Human Development Index – a cumulative average of per capita gross domestic product, life expectancy and educational attainment levels – is moderate at 0.756. This places Chongqing slightly below the national average of 0.78, but far behind its coastal counterparts who are around 0.9, and even regions in central China that are around 0.8.

Additionally, it is facing a more affluent and demanding population, greater resource and infrastructure constraints and severe environmental pollution. The city is infamously known as the "furnace of China." Indeed, Chongqing's environmental degradation has reached a point where it now jeopardizes the city's long-term economic competitiveness.

For Chongqing to continue to be economically competitive, support its existing and emerging industries and attract and retain critical human capital, it needs to develop sustainable urban planning and infrastructure. While Chongqing has made notable efforts in this area, especially in its master plan, much more can be done in a more coordinated fashion.

3 SUSTAINABLE URBAN PLANNING AND INFRASTRUCTURE

From this point of view, urban planning involves high density, multifunctional, mixed-use living, with extensive greenery and biodiversity that responds to microclimatic conditions and reduces climate change effects. Industrial considerations include location, orientation and and use.

Resource efficiency is important for energy, water, waste, transport and agriculture. This first involves optimizing demand – decreasing the need for energy, water, and travel, and limiting the waste produced. Once all reasonable efforts to reduce demand have been implemented, the next focus should be on making the quality and supply of resources as efficient as possible. Resource-intensive industries should be discouraged, and instead the focus should be on the following:

- Energy: Stronger building codes, audits and rating systems. Developing more expensive renewable energy should be the last option, though Chongqing's agricultural base provides good biofuel potential. Industry should consider energy efficiency agreements, manufacturing, processing and clean technology opportunities.

- Water: Better watershed management, pollution prevention, water quality, sustainable agriculture and technologies to provide quality and reliable water supplies, such as rainwater harvesting, water capture and recycled water management. Industrial considerations include quality and quantity of storm water runoff, wastewater treatment and monitoring discharge.
- Waste: A resource waste management strategy follows reduction, reuse, and recycling principles in construction and post-construction phases, promotes circular economy strategies and applies energy recovery technologies. Industrial considerations include waste streams, co-location and the promotion of industrial symbiosis.
- Transport: When travel is needed, it should be undertaken by walking, biking or public transport, including bus rapid transit. Cars should be the last option, and inhabitants should be encouraged to use car clubs or electric/hybrid vehicles. A Low Emission Strategy provides a package of measures to help mitigate the transport impacts of a development, and provide further access and ease of travel for industries and people, connecting external and internal transport systems. Industrial considerations include travel mode and frequency by industry and household for both leisure and work.
- Agriculture: Having a healthy, stable, affordable, and local food supply has always been the backbone of China's self-sufficiency food mandate. Traditional industrial farming practices should change to a sustainable food production model by adopting small scale farming enterprises, which promote more labor intensive modes of production, technological pluralism, greater adaption to local resources for higher agricultural productivity and improved resource efficiency. Industrial considerations include resource input and output factors for enhanced production and better production methods.

4 SUSTAINABLE INDUSTRIES

Resource prices should be competitive, determined in terms of implications for society. Consumption should be metered for informed tracking, with policies to encourage better choices and discourage negative practices. The most effective way for Chongqing to move towards a sustainable model of economic development is to take a holistic, integrated approach to identifying solutions, one that is grounded in an understanding of the social and economic cost of inaction. Breaking the vicious cycle of unsustainable development requires an understanding of how these issues are inter-related, controlled and influenced not only through technological means, but also through policies, planning and education.

Chongqing has identified eight pillar industries that it wants to develop, expand and promote: Automobiles and motorcycles; equipment manufacturing; electronic information; biopharmaceuticals; logistics; business and trade; service outsourcing and finance. In light of the sustainable infrastructure and planning opportunities highlighted, and considering the integrated systems approach, there are many opportunities for these industries to develop in a more environmentally-friendly and sustainable manner.

They include reducing the resource intensity attributed to manufacturing and distribution, minimizing the hazardous waste produced, applying industrial symbiosis to co-locate and share resources; establishing environmental and health quality-control management systems and creating an attractive and distinctive urban space.

Urban competitiveness is defined as "a city's ability of creating more wealth in a faster and better manner than other cities in the world." [1] Traditionally, the three key components considered vital to economic competitiveness have been[2]:

- (1) Providing adequate infrastructure (transportation, telecommunications, water & sanitation, etc.).
- (2) Improving public services (education, health, public security, housing, etc.).
- (3) Reducing the cost of doing business (e.g., fast processing of new business licenses, tax incentives, labor laws, economic zones with special privileges, etc.).

[1] Global Urban Competitive Project. http://www.gucp.org/en/
[2] Ming, Zhanga. "What Can Cities Do to Enhance Competitiveness? Local Policies and Actions for Innovation," *En Breve*, The World Bank. 2008.

Chongqing has made great strides in creating an attractive environment that is conducive to business. It has low costs for labor and resources, and is improving its transport and infrastructure. However, its poor environmental health and quality of life have deterred industries and people, especially highly-skilled workers and tourists, from coming to the city. It has not invested enough in innovation and human capital. Research and development need to be applicable to industry. Education should be translated to the needs of the market at all levels and job types.

5 STAKEHOLDER COLLABORATION

Collaboration between stakeholders is essential to transforming Chongqing into an economically competitive, sustainable municipality. Stakeholders include the local government, the public and industry. Each has a role to play in developing, promoting and participating in initiatives that support sustainable economic development and share a sense of urgency to drive decisive action.

- Government: The government sets the vision, with a long term strategic development plan and qualitative and quantitative targets. It should present bold and innovative actions, but also communicate and coordinate with other stakeholders to reduce risks of uncertainty. Heavy investment in sustainable infrastructure, education and evaluation should be made. Government should demonstrate by example and be sensitive to the needs of its constituents, especially the less fortunate in society.
- Public: Their mobility allows them to obtain the best skills, practices and knowledge; and to promote Chongqing nationally and internationally. Increased affluence, technology and education puts the population in a better place to demand greener products and processes from industry.
- Industry: Industry's role can be divided into three areas to take advantage of various sustainable opportunities: core business (the products and services a company makes and how they are designed), sustainable operating practices (the systems, practices and processes used by companies to manufacture and assemble their products and operate their facilities) and external relations (the leadership role that companies can play within their industry, supply chain and communities).

6 CONCLUSION

Chongqing is at a crossroads. Continued economic growth using the traditional industrial model will accelerate environmental damage, deplete natural resources, jeopardize public health and deteriorate the quality of life, which eventually could drive people and investment away as well as offset the economic gains achieved through growth. For Chongqing to fulfill its dual goals of retaining economic competitiveness and setting the model for development in the west, it needs to apply a sustainable, integrated development model. Such a model would assess the local context in urban planning and infrastructure; and promote resource efficiency, industrial symbiosis, and greater collaboration and leadership for industry.

Chongqing can fulfill its vision as a center for sustainable industries, and set the path for sustainable development and economic competitiveness if it acts creatively in a coordinated manner.

City environment: Regional development dimension. Baltic case

Ilze Stokmane

(Mg.oec. Ilze Stokmane, Latvia University of Agriculture, 2 Liela Street, Jelgava, Latvia, LV-3001, Ilze.Stokmane@llu.lv)

1 ABSTRACT

Economic processes underway in the country directly and indirectly affect the welfare of the people and the social environment, starting with job security and having a direct impact on the qualitative and safe living environment.

Population differences of wealth are defined by uneven distribution of resources and economic activities within the countries, which affects also population welfare level in rural areas. There is a higher level of welfare of the people observed near cities in Baltic States. The relatively small distances to the city restrict labour everyday mobility. Settlement structure in the Baltic States since 1920 have greatly changed, which clearly outlines the population preferred the social environment.

The article describes existing situation and gives analysis of the regional development policy determination and implementation in the all three Baltic States. According statistical indicators there are differences between implementation of the regional development activities between all Baltic States and in regions of inside each country.

The author is analysed more detail differences between regions in Latvia, Lithuania and Estonia according possibility to evaluate success of development processes in regions of the Baltic States. The descriptive analyse of documents, statistical indicators at national level and regional level were used in the research.

2 SOCIAL ECONOMIC ENVIRONMANT OF THE BALTIC STATES

Baltic region consists of three small countries: Estonia, Latvia and Lithuania, and it look like a miniature model of the European nations. In large geographical scale it is advisable to include these countries into one group - the Baltic States.

As long as there are differences, there is regional identity in the Baltics. Close trade ties among the Baltic cities within Hansa, the union of city-states, is often mentioned. It brought prosperity to the entire region in the Late Middle Ages and left traces still visible in the capitals of the Baltic States. In the 20th century during the short period of independence between 1918 and 1940 political initiatives for the purpose of the development of regional identity, including formation of the Baltic Union (with Finland and Poland) and a plan to establish customs union between Estonia and Latvia, emerged in all three countries. During the Soviet regime similarity of the Baltic States was taken into account when planning economy.

Despite the geographical proximity of the three countries, it is hard to miss the essential historical, ethnic, cultural and social differences in the region. Traditionally they were formed from smaller settlements that historically grew to a large trade centres. State territorial and administrative borders remained unchanged, according to the current government and its military achievements and needs. There were similar trends observed in Baltic economies. However, countries today are at different growth level of development, which clearly confirmed by macroeconomic indicators.

On the one hand the Baltic States have always served as a bridge between the East and the West where their development was facilitated by the great potential for growth due to the respective trade and business ties.

States on the shores of the Baltic Sea can use many economic cooperation possibilities. In this aspect geographical position of the Baltic cities is advantageous, and they have received significant foreign investment with a substantial contribution from neighboring Nordic countries. These factors stimulate specialization of the production network and vertical specialization that may serve as an important source of static and dynamic efficiency.

After the restoration of independence all three Baltic States adopted similar price liberalization policy trends. They chose about the same development scenarios and methods as transition states in the Central Europe with greater progress levels.

Although according to international experts quality of the business environment in Latvia is comparatively only slightly behind that of the neighbor countries Estonia and Lithuania, it is essential to at least maintain

this level under the current conditions of the global economic crisis. Environment favorable to economic activity is the key aspect facilitating investment flow to the country, creation of new jobs, and gross domestic product (GDP) growth. All of these factors are critical for Latvia to get out of the present economic hole.

State can improve its general business environment by investing in infrastructure, education, and other resources available to all companies based on equal competition thus decreasing their operating costs and increasing efficiency of labor.

Despite aspirations for economic integration, economic likeness, and perception of national interests, cooperation of the Baltic States has also caused contrary effects. Since on a large scale capital and labor capacities are very similar, they manufacture almost the same types of products and compete for the same exterior markets; gains from the interior interstate market in the Baltic States are not great.

Starting with the Treaty of European Union, the conception about cohesion was further defined and was understood the decrease of developmental levels between the different regions, not the general division between the regions.

In general Estonia, Latvia, and Lithuania as member states of the EU gain considerable benefits and advantages thanks to the greater influence of EU common foreign trade policy on international level as well as due to increased availability to third country markets provided by EU free trade treaties. As a result of EU expansion the largest common market with more than 450 million consumers has been created. Thus Estonian, Latvian, and Lithuanian businessmen may sell their products in other EU member states and member states of the European Free Trade Association (Norway, Switzerland, Lichtenstein, and Iceland) making use of the advantages of the free movement of goods, services, labor, and capital. While for the Baltic States as EU member states foreign trade means trade with third countries where the major foreign trade partners include Russia, USA, Belarus, and the Ukraine etc.

It is equally important for the EU member states to maintain the social welfare, to provide conservation actions, health security, and educational system, decrease the crime rate, increase the quality of services and provide growth and development for scientific work and development in general.

Although the average level of consumer prices in the Baltic States is roughly the same, the way it has been achieved differs across countries - high and low inflation periods are not equally pronounced and causes of inflation differ.

Based on the institutional analyses on the European Union action principle and formation of the regional policy, the author understands that terms for long lasting economical growth are development, competition and employment.

In the last decades not only the country, using the central governing institutions and local authorities, is active in the implementation of the regional policy, but also the European Commission and other international organisations (Vaidere, 2006).

There can be observed quintessential social economical differences between the regions in the EU. The big social economical differences slow down the EU in general, as a whole, and each region of each state, even the wealthiest slow down in growth. Therefore one of the EU priorities by realizing the solidarity principle (European Commission, 2009) is the economical and social reconciliation (cohesion).

The main investment areas in Baltic States are financial intermediation and real estate and renting. In the newest Eastern Europe Outlook (2009), considering the economic situation of the Baltic States, specialists of SEB Bank point out that the recession of the global economy is over, but the recovery is equivocal and there are still many risks. The recovery of economics, especially in Latvia and Lithuania, depends on the stabilization of state finances. Swift changes have reduced unbalances in economies. Low purchasing capacity and increasing unemployment will continue to force drop in prices.

Governments will be forced to keep implementing sharp and unpopular cost optimization measures. Significant prerequisites for the recovery of the region will be the financial stability of those countries and the recovery rate of external markets.

Economic processes in the country have direct and indirect impact on the welfare of population and the social environment, starting from job security, and have direct influence on qualitative and safe living environment.

Several important priorities are established for the development of the social field in some policies of European Union – to create conditions for sustained growth and employment, where a potential obtained from one market could be fully used, to develop "know-how" policies stimulating scientific activities and technical development in the EU countries, increasing educational level and developing educational programs; to streamline employment systems; to increase the quality of life by guaranteeing economical development in an integrated society by improving public health condition, environmental protection and implementing policies for the establishment of freedom, safety and justice regions.

Currently the initiatives to be implemented in the field of employment, social and health areas are additions to the revised strategy of Lisbon (Treaty of Lisbon, 2007) oriented to economic, social and environmental regeneration. The strategy of Lisbon envisages "making the EU the most dynamic and competitive knowledge-based economy in the world capable of sustainable economic growth with more and better jobs and greater social cohesion, and respect for the environment".

Participants of the economy need time to change their consumption habits. Since mid-2003 the rise of inflation has been stimulated by external and internal processes – the global rise of oil prices took up, fundamental tax law changes took place in the Baltic States due to the joining the EU, import prices increased because of the EUR value increase, the pressure of the supplying party on the inflation hardened. In its turn, wider availability of credit opportunities, income sent home by persons working abroad as well as EU funding increased the domestic demand simultaneously having strong impact on the interaction of supply and demand factors.

The population has been ageing, i.e. the share of elderly people compared to the total population increased. In Latvia there are 467 thousands retirement pension receivers per approximately 1.15 millions of employed population, which means that approximately 2.5 employed persons have to support one retired person. In Lithuania 1.5 millions employed persons have to support 596 thousands retirement pension receivers, which means, that like in Latvia one retired person is supported by 2.5 employed persons there. Only in Estonia one retired person is supported by 3.6 employed persons. Also social insurance payment volumes are similar in all three countries, respectively, in Latvia 33.09% are paid in total, from which 20% are payments into the pension capital, in Estonia the social tax is also 33%, from which 13% are allocated to medical insurance and 20% – for provision of pensions, and in Lithuania the tax is 30.7%, from which 23.85% are allocated to the social insurance of pensions that is for some percent points more.

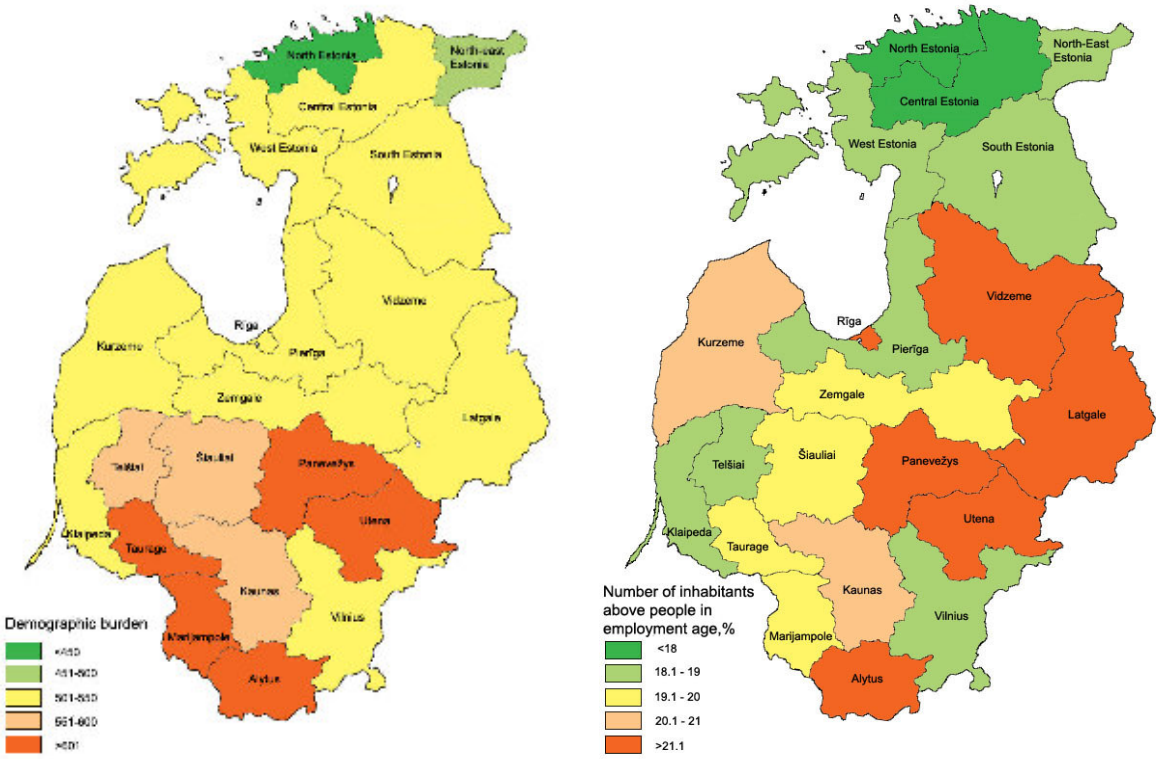

Fig. 1: Demographic burden and number of inhabitants above employment age in Baltic States, % of total population, 2008

The allocation of labour forces is strongly subordinated to the economic activities, respectively – allocation of employment possibilities, consequently the demographic burden varies in different territories. In the territories with more jobs and higher remuneration possibilities, especially in cities and their surroundings, there is a higher concentration of able-bodied population, whereas economically not so active rural regions are mostly populated by retired persons, not looking for employment possibilities any more.

Differences in welfare levels of the population are determined by uneven allocation of resources and economic activities in the countries causing highly different welfare levels of the population in different rural areas. Higher welfare levels of the population are near the towns, where relatively small distance to the town does not limit everyday mobility of labour forces.

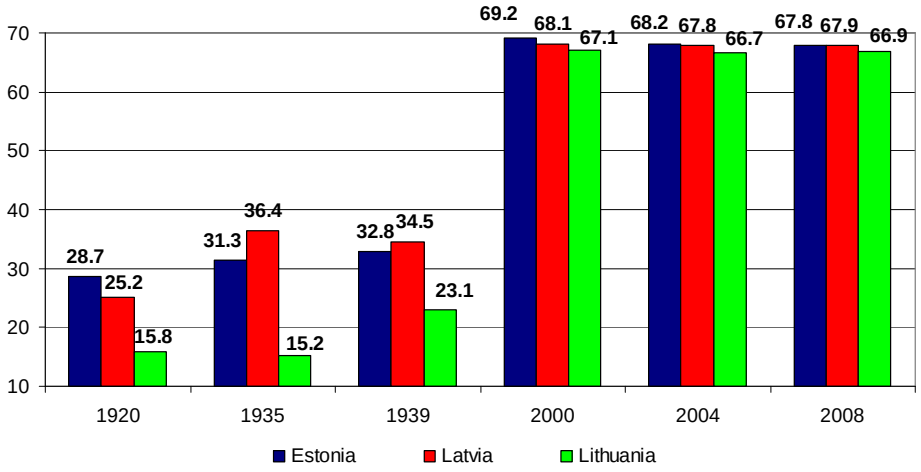

Fig. 2: Urban population, % from total population in country

The structure of the population in the Baltic States has strongly changed since 1920, which clearly defines the preferable social environment of the population. During the first independency more than one third of the population lived in towns, in year 2000 almost two thirds of the population of the Baltic States has chosen the city environment as their place of residence (Fig. 2).

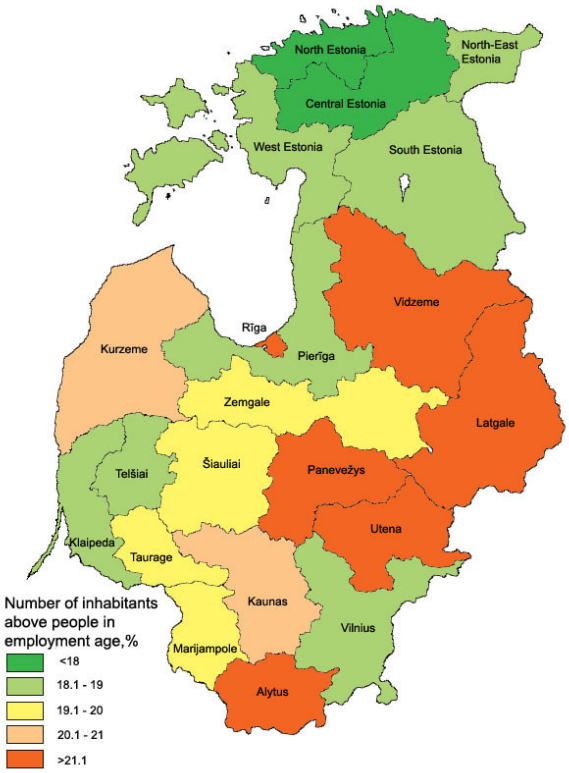

Fig. 3: Urban population in the regions pf the Baltic States, 2008

Among the population of Lithuanian regions there is a tendency (more than in other Baltic States) to choose towns as their permanent place of residence (Fig. 3). At the beginning of 2009, 66.9 per cent of Lithuania's population lived in towns on the major part of its territory. Over 2000–2008, the share of the urban and rural population remained almost unchanged (Statistical Yearbook of Lithuania, 2009).

In Estonia and Latvia the ratio of the urban population (more than 50% of the population living in towns) makes little bit less than a half of the total territory. In the region of Central Estonia the ratio of urban population makes just 21.4% of the total population of the region, but in region of the Baltic States (including capitals) the ratio of urban population is between 78 to 83% of the total population in the respective region.

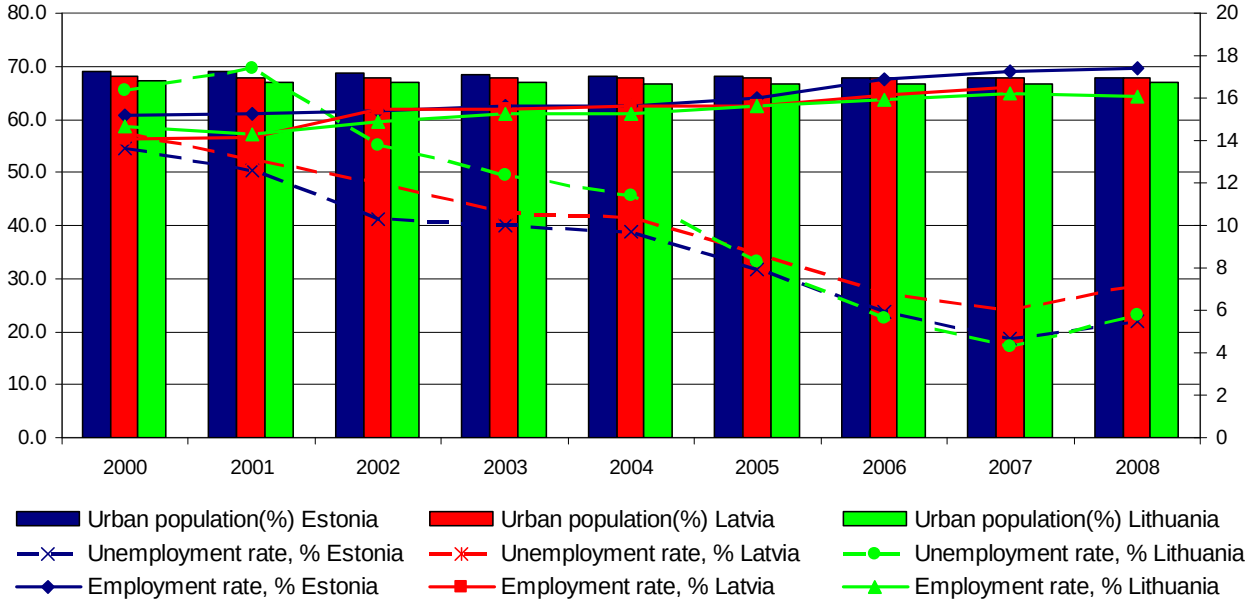

Fig. 4: Urban population and employment indicators in Baltic States during 2000 – 2008

Also the number of the unemployed has been annually decreasing. The employment level in the Baltic States has increased in the last eight years (Fig. 4). The highest number of the unemployed had been recorded in 2001, while in 2007 – 4 times less than in 2000. From 2001 to 2007 the unemployment rate in all three Baltic States was decreasing, but from 2008 it has began to increase and, according to the EUROSTAT data, a big leap is prognosticated in 2009 – in Latvia up to 19%.

Due to decreasing employment possibilities the unemployment increased in 2008 among persons with low educational level as well as among persons with high educational level. Persons who have only general education had remarkably more problems with finding a job (Statistical Yearbook of Estonia, 2009).

Changes and influences on the labour market reach other fields but at different time, this also applies to other fields which are influencing the labour market. In case of mutual relation it is unclear what field has stronger influence but in most cases it is easily discovered, which field is stronger (Statistical Yearbook of Estonia, 2009).

Comparing the volume of natural growth in the 20s and 30s of the 20th century with today's tendencies we can see sharp differences – in the beginning of the 20th century the natural growth was positive in all the Baltic States (Fig. 5), but at the beginning of the 21st century, comparing indicators of the demographic situation, we can trace negative tendencies in the changes of population numbers.

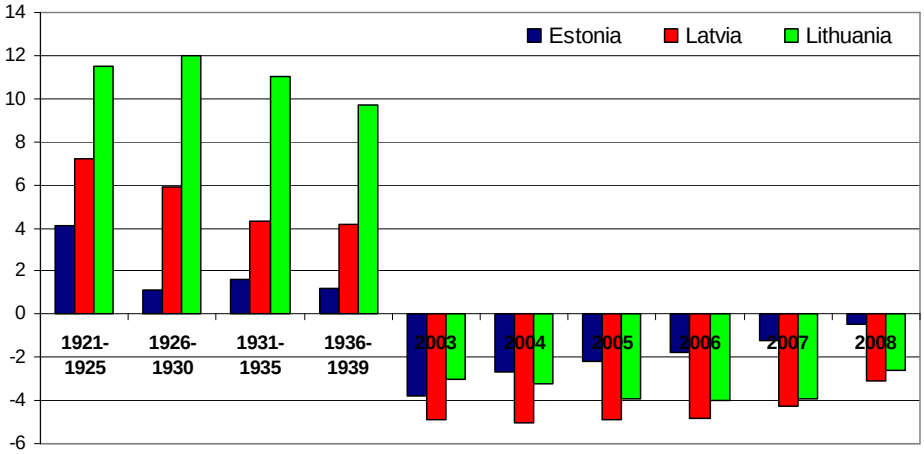

Fig. 5: Natural growth in Baltci countries

During the last three years a negative growth tendency can be observed mostly in regions of Latgale and Utena where the natural growth indicators were -9.1 and -7.2 per 1000 inhabitants respectively. The main reason of the decrease in population is not only the natural decrease, but also international migration that can be observed on all the territory of the Baltic States. As from 2006 the situation in all the Baltic States has been improving and we can see the increase in birth rates.

There is a tendency characteristic of the capitals of the Baltic States to oppress economic potential of other areas of the respective state, thus total growth is generally accounted for by the state's capital. Author reminds that the key prerequisite for common development of the cities is their willingness to become part of the collective network and cooperation among the most important participants in the field of politics, economics, and administration.

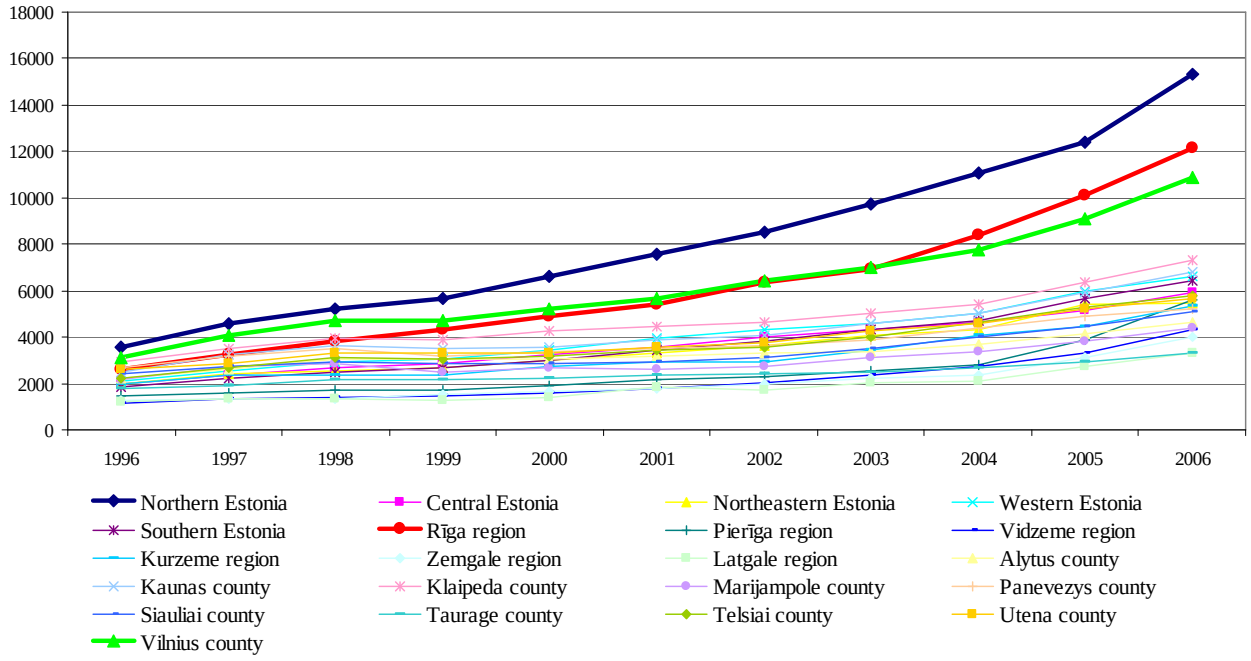

Fig. 7: Regional GDP per capita n Baltic States

Region of Riga accounts for a substantial share of the state economy of Latvia – in 1996 it was 46.5%, in 2006 – 57.3% of Latvia's GDP, the remaining share is accounted for by the rest of the regions (Fig. 7). Whereas Northern Estonia accounted for 53% of the state economy in 1996 and 61.1% - in 2006, and region of Vilnius accounted for 28.6% of the GDP in 1996 and 36.9% - in 2006.

In 2006 GDP per head in Vidzeme was as many as 9 times smaller than in the region of Riga, other regions showed only slightly higher rates – in Zemgale it was 8 times smaller, in Latgale - 7.5 smaller, in the outskirts of Riga and in Kurzeme - 5 times lower than in the capital.

In Estonia the situation is similar – in Northern Estonia, where the capital Tallinn is located, the rate was even 9.5 times higher than that of Central Estonia. Northeastern Estonia showed GDP per head 8 times smaller than Northern Estonia, in Western Estonia it was 7 times lower, and in Southern Estonia - 3.5 times smaller than in Northern Estonia where the capital Tallinn is located.

In Lithuania the difference in respect of GDP per head among regions is even sharper – region of Taurage showed even 20 times lower share of Lithuanian economy than region of Vilnius, Marijampole and Alytus counties were also behind by more than 10 times, Utena and Telsiai counties showed a value 8 times smaller, the rate was 5 times lower in Panevezys County, 4.8 times - in Siauliai County, 3 times - in Klaipeda County, and GDP value was almost 2 times lower in Kaunas County.

Sharp differences in respect of GDP rates across the Baltic regions may most clearly be observed in diagram (Fig. 8) where data of the capital regions differs considerably.

During the period (1996 - 2006) discussed in the study basic growth rate of GDP per head in Riga Region (taking 1996 as the base year) was 363%, average growth rate was 17%. Whereas other regions of Latvia did not show such a rapid economic growth, and the average growth rate in regions across Latvia ranged from 11 to 15%, 11% in Kurzeme and Latgale, 13% in Zemgale, 14% in Vidzeme, and 15% on the outskirts of Riga.

In Estonia basic growth rate of the Northern Estonia was 335%, while the average growth rate was 16%. In other regions it showed the same tendency as in Latvia ranging from 11 to 13% - 11% in Northeastern Estonia, 12% in Central and Western Estonia, and 13% in Southern Estonia.

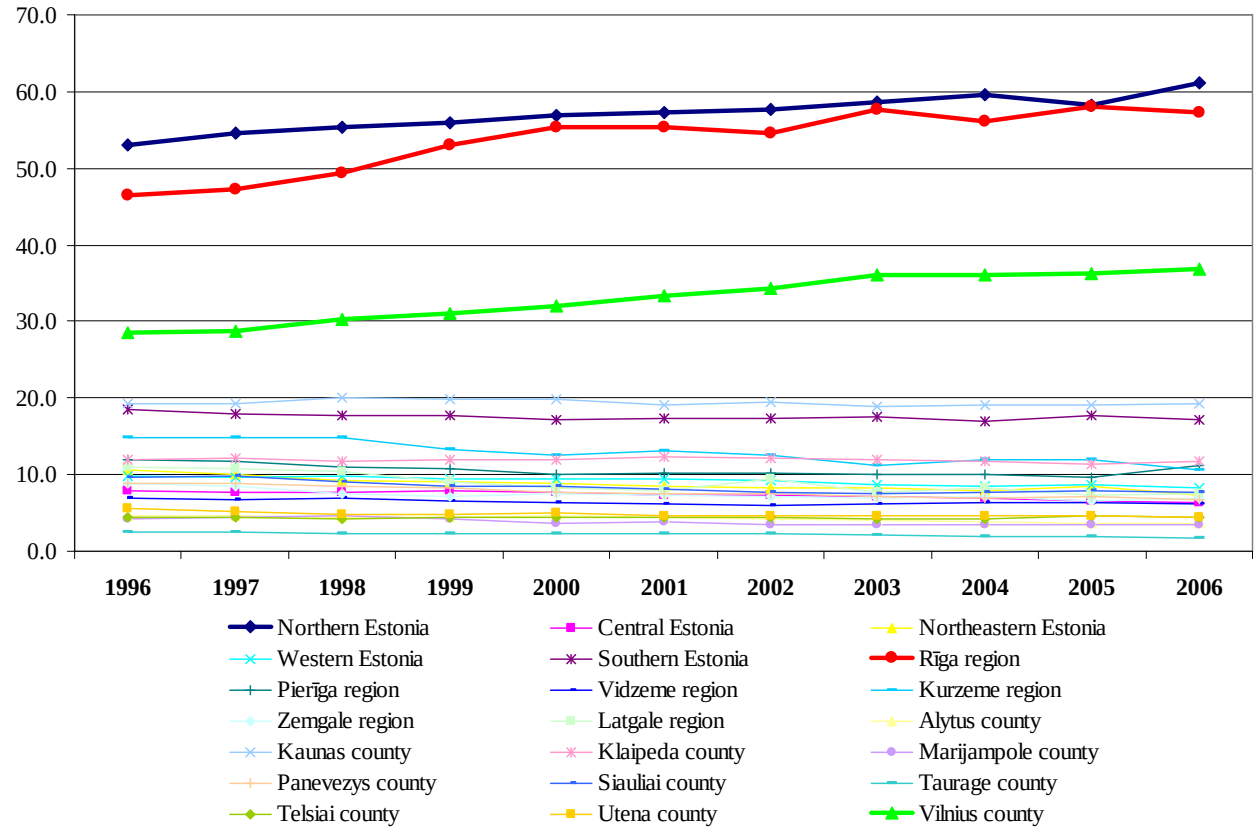

Fig. 8: Annual regional GDP in Baltic States during 1996 – 2006, % of GDP within each country

In Lithuanian the average growth rate was slightly slower - 14% in Vilnius Region, 6% in Taurage County, 7% in Panevezys County, 8% in Alytus, Marijampole, Siauliai, and Utena counties, 10% in Klaipeda un Telsiai counties, and 11% in Kaunas County.

The life rhythm in modern day Europe is fast. To solve problems that affect us not only in Europe, but also outside it, the legislation needs to adjust to the fast growing technological development and need to further

innovations that could protect the wellbeing and security of the inhabitants of Europe. The public offices and authorities need to be effective, flexible and determined. These are the standards that the European Commission (2009) has set for themselves.

The public authorities adopt legislations for the society to reach numerous goals - to provide fair trade and competition, provide health security and security, further innovations and protection the environment. When developing the policies and legislations the government tries to obtain betterments – make sure that the right instruments are used for the corresponding task, the gains are maximized and the negative influence is minimized, and they make sure to listen to those who are directly influenced by these actions. Therefore the author is convinced that the legislation is a tool that makes policies become reality and realizes the needs of citizens.

The international dialog and collaboration is extremely important not just because of security of high consumer rates and social and environmental protection, but also from the perspective of business development. Just like the creation of a single market in the Europe was set by the company needs to get rid of the unreasonable differences in norms between the member states, the international collaboration motivation is to scale down or liquidate excessive formalities between the business partners.

3 COMPARISON OF THE REGIONS OF BALTIC STATES USING FACTOR AND CLUSTER ANALYSIS

As in the past, even today we can talk about each country individually as well as of single region. Further analysis of the regions of the Baltic States is done at NUTS III level according to Eurostat's defined statistical regions of Europe.

Each administrative territorial units (parishes, towns, districts, counties) and regions can be described using many different parameters, and each of them can form different spatial clusters. Particular importance of these characteristics is among those that may serve as indicators, both describing the situation as a whole and find a causal relationship, as well as emphasizing the ongoing processes.

Based on the assumptions that there are complex interactions and relations of dependency between variables and parameters and thereby the possibilities of reduction the information, it is necessary to apply the method of gathering information, which remove the relevant information from non-significant one and indicates interrelationships.

Based on a set of indicators that characterize the Baltic country's socio-economic development using factor analysis it is useful to form a small number of complex factors that can not be observed directly and which are not correlative to each other and describes the overall structure in the initial factor system.

Factor analysis method allows dealing with some approximation of a very substantial research task - based on the wide array of information processing, to develop the classification scheme with an explanatory description.

Studying the characteristics of a system with factor analysis it is possible to reveal the logical structure of complex phenomena, to distinguish between independent and substitutable indicators, relevant from the irrelevant, and to justify the choice of indicators system and assess its information load, as well as to test hypotheses on system regularities of the indicators (Field, 2000; StatSoft, 2003; Patria, 2007).

The choice for usage of factor analysis in work was the essence of the method - identifying the links between the initial indicators and get a smaller number of factors, which characterizing the socio-economic development of the Baltic regions, and describing their competitiveness.

Initial indicators corresponding characteristics of territory and living environment has formed 3 complex factors using factor analysis which generally explains 69.8% of information. The first factor explains 32.2%, the second - 24.5% and a third - 13.1% of information.

Factor	*Initial Eigenvalues*		*Indicators*	*Component*
	Total	*% of Variance*		
Quality of living environment	4.186	32.2	Level of demographic burden (2008)	-0.840041
			Number of dwellings per 1000 inhabitants (at the end of 2007)	0.830591
			Housing stock average per inhabitant, m^2 (2008)	0.732723
			Number of beds in hotels and other accommodation establishments per 1000 inhabitants (at the end of 2007)	0.719869
			Number of visitors in hotels and other accommodation establishments per 1000 inhabitants (at the end of 2007)	0.829385
			Recorded criminal offences per 10000 inhabitants (at the end of 2007)	0.762847
			Sown area, thsd ha (at the end of 2007)	-0.541485
Attractiveness of living environment	3.179	24.5	Population density, population per 1 km^2 (2008)	-0.653436
			Immigration per 1000 inhabitants (at the end of 2007)	0.653294
			Emigration per 1000 inhabitants (at the end of 2007)	0.837291
			Urban population ratio, % of total population in region (2008)	-0.860151
			Forest cover, % of total area (at the end of 2007)	0.639959
Accessibility of territory	1.709	13.1	Road traffic accidents per 1000 inhabitants (at the end of 2007)	0.91566

The result of factor analysis describe the quality of living environment – the higher value of the first factor belongs to regions with bigger amount of housing stock and number of dwellings calculated per 1000 inhabitants what is characteristic for urban area. Those regions have also more visitors stayed in hotels and other accommodation establishments and number of beds in those establishments calculated per 1000 inhabitants. As negative feature characterizing the same regions should be mentioned higher level of recorded criminal offences per 10000 inhabitants.

By contrast the characteristics of the demographic burden and the sown area of agricultural land is part of the package that form factor with a negative component, which means that the region has low dependency ratio and low agricultural crops.

The higher value of the second factor describing attractiveness of living environment within the region the bigger migration flows of population and more forest cover in territory. At the same time there is lower population density and wherewith lower urban population ratio characteristic for those regions.

The third factor describes accessibility of territory and the higher values of this factor characterise regions with more road traffic accidents calculated per 1000 inhabitants.

These complex factors clearly show interaction of urban and rural areas and characteristic marks typical for urban and rural environment.

Further study was done using cluster analysis, which is a statistical analysis method, and can be used to set up essential groups of similar objects. The main purpose and challenge of this method is to form groups of investigated objects into clusters, based on certain representative comparison of parameters. However, different groups of elements should be divergent. The cluster analysis was done by SPSS program.

The author chose the optimal regional allocation of 6 groups, which further described in the work.

Factor / Cluster	1	2	3	4	5	6
Quality of living environment	1.48389	1.34060	0.58582	0.59162	-1.03904	-0.54831
Attractiveness of living environment	-1.19455	0.90629	1.61198	-2.72410	-.38052	0.08945
Accessibility of territory	-1.12623	-0.16568	1.72472	2.25487	-2.21580	0.07582

This table shows the values for the final cluster centres. The values in the table are the means for each variable within each final cluster. The final clusters centres reflect the attributes of the prototypical case for each cluster.

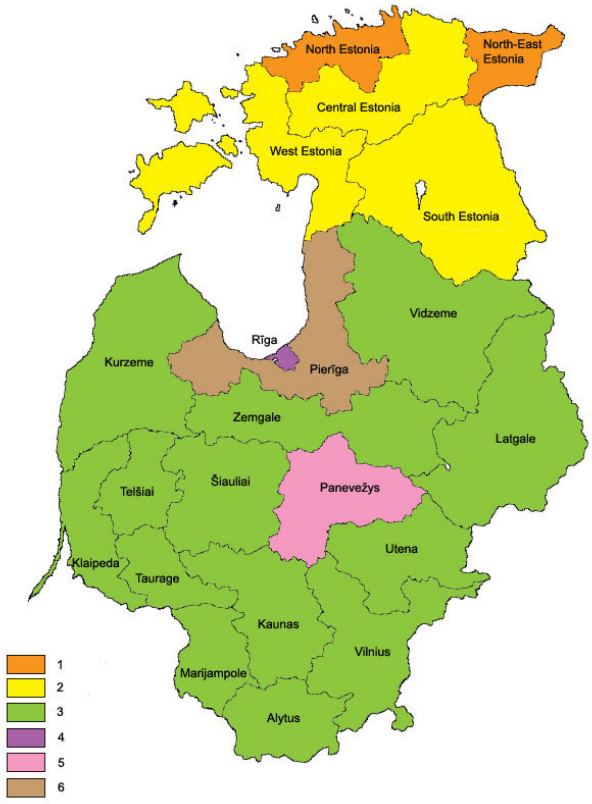

Fig. 9: Clusters of territory and living environment factors

The author, along the traditional statistical analysis, analysed clusters using cartographic method, which gives an overview of the diversity of circumstances in the Baltic region. During cluster analysis for selected complex factors it was made 6 groups obtained following distribution of Baltic regions (Fig. 9).

4 CONCLUSION

The regional policy often is called the structural policy because in the result of implementing the regional policy the regional and state economical and social structures change.

For the regional development and promotion of competitive capacity in the Baltic States in 2007-2013 large means of structural funds for different programmes of business activity and research development therefore promoting the state and individual region competitiveness from the European Union are available.

More similarities in management of social and economic processes have Latvia and Lithuania. Promoting cross border cooperation between regional and local municipalities in Latvia and Lithuania it is possible to foster economic growth jointly addressing the cultural, industrial and social problems.

Rational use of available resources in regions is an investment in future development, promoting better interaction between regional bodies and thus improving the living conditions and future economic development.

Regional disparities and increasing gap between regions within the Baltic States and the Baltic States themselves justifies the need for implementation of long-term development policy and spatially differentiated approach to regional support to provide solutions to specific problems in the region mostly using the existing resources and potential.

The author suggests using different instruments for support of regional development at state level and local (municipality) level to foster the effect of support actions:

State level: Subsidies, loans, donations; Investments; Differentiated support for problematic regions; Rationing of resources consumption.

Municipality level: Finance, credits, warranties; Consultancy, employment training; Licensing, certification, privatization; Development of organizational structures.

Confronting the Lagos Informal Land Use: Issues and Challenges

Oluwafemi Olajide

(Oluwafemi Olajide, Department of Geography and Planning, Lagos State University, Ojo, Lagos, Nigeria, olajideao@yahoo.com)

1 ABSTRACT

Lagos represents one of the cities with the fastest growing urban agglomerations in the world. Rapid urbanisation coupled with inadequate public resource has given rise to peculiar land development system that is, informal land use. It has been observed that formal land management system has continuously failed in providing land for housing and other uses, registering titles and land transfers, regulating access to and use of land as well as providing basic infrastructure services. The shortage of the formal system has, however, been largely compensated by the increasing importance of an informal system in land development. This paper addresses the main issues and challenges of informal land use in Lagos State and how it can be integrated into urban development so as to achieve a sustainable, healthy and livable urban settlement. Major issues and challenges confronting informal land use as identified by the paper include uncontrolled and conflicting land use, Unplanned growth, illegal squatting, overcrowding, inadequate or lack of basic services and infrastructure, continuous rise in incidence of informal land use, insecurity of tenure, poverty and worsening environmental conditions, marginality, exclusion and vulnerability among others. Therefore, it is imperative to confront the incidence of informal land use through the use of adequate and sustainable means of land use management system, informal land regularization that guarantees security of tenure, urban growth and housing strategy to address shortage of affordable and adequate serviced housing, massive provision of basic services and infrastructure and improved urban land administration.

2 INTRODUCTION

In sub-Saharan Africa, land defines the social, economic and political relations in the society. Especially in the urban areas, it provides the basis upon which planners predicate their strategies of development (Wanjala, 2002). However, It has been observed that in many third world cities, urban land can either be obtained formally or informally, and that the informal sector provides much more land to land seekers (including the majority of the poor) than the formal sector. Nevertheless, the mechanisms of the informal land sector are usually ignored and are hardly understood and documented. (Mabogunje, 1990).

The informal sector encompasses a wide range of areas of informality — environmental, spatial, economic, and social, covering business activities, employment, markets, settlements, and neighborhoods. Most urban households in the developing world live in informal settlements due to their often exclusion from formal systems of land management. Up to 85 percent of new housing is produced informally, a trend that is especially pronounced in sub-Saharan Africa and particularly in Nigeria (Nkurunziza, 2007).

Land policy is an important tool in spatial planning and planning administration. The structure and pattern of any settlement is a reflection of laws that regulate land administration. The past and existing patterns of development within Nigeria settlements are a function of land laws and administration (Oyesiku 1998). Prior to 1978, land administration in Nigeria had been predominantly guided by customary laws. This system recognized the interest of individuals, families and communities on land. Therefore, all the people have equal right of access to land, while the chief or head of the family is the trustee who holds the land for the use of the people. Acquisition of land for use under the customary law is normally through a grant by the chief of the community or head of the family. Alienation or transfer or terms of grant are restricted to strangers (Yakubu, 1985). Today, land tenure in Nigeria is governed by the Land Use Act of 1978 under which all land in all the states of federation is vested in the Governor. Access to land is by way of a 'right of occupancy' granted by the government. This development had led to a lot of controversies in the acquisition, disposal, use and administration of land especially in the urban areas due to increase in the demand for use of land which is brought about as a result of high rate of urbanization.

With the present trend of rural urban migration in Nigeria as epitomised by the situation in Lagos being the commercial and industrial hub of the country – with a land area of about 3,345 square kilometers, which is just about 0.4% of the total land area of country. It is physically the smallest but the most populated and urbanized state in the country with population of over 10 million inhabitants which is about 10 percent of the entire population of the country. Therefore, it is not unexpected to observe unusual pressure, leading to

unprecedented demand for land. Through the pressure being mounted by the demand for land, it is a common phenomenon to see most undeveloped land being taken over informally by the rural immigrants

who are mostly poor in order to satisfy their urban land needs. Consequently, such invasion or informal development usually leads to uncontrolled and unorganized developments, while such neighborhoods/communities lack basic infrastructural facilities which are needed for healthy living. The rapid rate of development, equally results to overall plannessless of these areas. It is against this background that the paper seeks to addresses the main issues and challenges of informal land use in Lagos and how to prevent informal urban development in order to achieve a sustainable human settlement worthy of living, working and recreating.

3 LITERATURE REVIEW AND CONCEPTUAL ISSUES

3.1 Informal Land use: definition and characteristics

There has been a considerable growth in the amount of literature on informal land use. Also, the research on the economic, social, and political forces that generate and sustain the incidence of informal development is abundant. This includes work by Payne (1989), Satterthwaite et al (1989), Arche (1992), Rakodi et al (1993), Kombe (1995), Durand– Lasserve (1996), Habitat (1996), and Kombe and Kreibich (2000). Many synonyms have been used in literature to refer to informal land use. These include spontaneous, irregular, unplanned, marginal, squatter and informal settlements (UNHSP, 2003c). Therefore, throughout this paper, informal land use is equated to informal development, informal settlement or squatter settlement.

The phrase informal settlements has been accepted as well as refuted by scholars in numerous disciplines. According to Leeds and Leeds (1978), the occupation of land that does not belong to the person settling on it is what distinguishes informal settlements from other settlements. The inappropriate invasion of land characterizes these settlements as an illegal form of land use because occupation is neither based on the legal ownership of such land, nor in payment of rent to its legal owners. In a study identifying the significant variables that determine the character of squatter settlements, Leeds argues that the only uniform identifying characteristics are their illegal and unordered origins or organized invasion and, because of their origin, their continued juridically ambiguous status as settlements (Leeds, 1969). Sietchiping (2000) refers to informal land use as any human establishment, human settlement or land use in the urban area which is not suitable and/or in opposition to the expected standard and regulations. Informal land use includes the poor and precarious housing within the city or in the city fringes or other areas where land are vacant, accessible and affordable.

According to Srinivas (2003) informal land use is characterized by unauthorized use of vacant public or private land, illegal subdivision and/or rental of land, unauthorized construction of structures and buildings, reliance on low cost and locally available scrap construction materials, absence of restrictive standards and regulations, reliance on family labour and artisanal techniques for construction, non-availability of mortgage or any other subsidized finance. Study by Sietchiping in 2000 revealed that informal land use is characterised by overcrowding, deterioration, insecurity, absence or insufficient basic facilities. These conditions endanger the health, safety or moral of the inhabitants and the livability of the community at large.

The development of informal land use - the evolution of what are now described as informal settlements- was blamed in the seventies on the tendency of the private land market to marginalize the poor (Gilbert and Ward, 1985; Turner, 1980). Informal land use according to World Bank (1999) constitutes an expression of poor urbanization and poverty of city dwellers as well as failed policies, bad governance, corruption, inappropriate regulations, dysfunctional land markets. Furthermore, according to Yapi-Diahou (1994) informal (settlement) land use originated from difficult problems of housing, immigration rate, politics, physical planning, landlessness, land tenure system and employment especially in the urban areas. In particular, they originate from the existing gap between the number formal/regular land supply and the need.

Land in the formal market remains too expensive for urban poor. Government allocations are slow and bureaucratic, and the land allocated for shelter considered insufficient. Recent empirical observations in nine African countries according to Mattingly and Durand-Lasserve (2004) provide evidence that Informal land systems are effective enough in terms of the quantity delivered to be an alternative to formal urban land delivery systems. They are less bureaucratic and more flexible than formal systems. They are more effective in reaching poor people. However, their viability, livability and sustainability raise a series of questions as

the system produces poorly planned areas with insufficient basic services as been experienced in Nigeria cities today.

Nigeria is one of the most rapidly urbanizing countries in Africa and the challenges that come with this especially in the supply of adequate land for basic services, housing and other uses are major challenges that government faces (FMH&UD, 2003). This had long been recognised by government therefore; attempt to meet these challenges led to promulgation of land use act of 1978 which seeks to nationalize the land tenure system in the country and entrusts the administration in the hand of the government. Nevertheless, in Nigeria today as epitomised by the situation in Lagos the informal sector is the dominant provider of urban land and housing, as only about 20% to 40% of the physical development in Nigeria cities is carried out with formal government approval. The weaknesses of government planning controls, and the haphazard developments associated with the informal sector have created disorderly and unhealthy urban environments (Nwaka, 2005). Generally, dwellings in informal settlements are built by the spontaneous, undirected and untrained efforts of the squatters who cannot afford to secure legal or formal land or a safe site on which a house can be built. Usually informal developments are located on vulnerable and areas such as deep or dangerous slopes. They are known as catastrophe prone areas Sietchiping (2000).

Informal land developments provide shelter for over 85% of the population of urban dwellers in most developing countries (UNCHS, 1996 and 2000; Durand-Lasserve, 1997). Yet, they either do not appear at all in government records or are regarded with so much negativism as to warrant constant harassment or exclusion from provision of necessary infrastructure and amenities (Durand-Lasserve and Tribillon, 2001; Agbola, 2005). As a result, actors involved in the informal and illegal land markets are denied access to formal opportunities for optimization of capital formation and accumulation.

Today, according to World Bank (2006) over two-thirds of the population of Lagos lives in the informal settlements or slums that are scattered around the city. The Lagos Master Plan 1980–2000 identified and classified 42 slums or informal settlements in the city. There are now over one hundred of such communities in Lagos. Many poor and low income families excluded from access to land and housing in the formal sector find refuge in the informal settlements where land and housing can be purchased and built according to means and capacity. Although, they generally lack security of tenure by virtue of not having the certificate of occupancy however, many informal settlement residents hold bona fide legal rights and interests in the land on which they live, having validly acquired land from legitimate land holding families or communities.

Driven by the quest to eliminate or drastically curb the incidence of informal settlements, the government has used forced eviction as a preferred tool of urban engineering with counter-productive outcomes. Generally, these evictions are planned and carried out without regard for the due process of law. In addition to the broad range of social, economic, psychological, cultural and physical havoc inflicted on the victims, forced eviction has helped to fuel the growth of new informal settlements or the expansion of existing ones with more complex dimensions. These communities are routinely denied funds needed for the provision or maintenance of basic facilities such as community health centres and portable water among others which are needed for a healthy living (Morka 2007).

It has been observed that there is lack of consensus regarding the status of informal settlements, especially the nature of their legality or illegality. The often cloudy statutory nature of the settlements is further complicated by a muddled policy environment and a often lukewarm stance by most Third World governments (Kombe 1995).The fact that the majority of settlers in informal settlements belong to the economically and socially marginalized groups seems to have worsened the reputation and increased the alienation of the informal land development by the policy makers. Government responses to informal land development in most developing countries have ranged from passing tough, stringent regulations to excluding them from infrastructure extension plans to barring their integration into urban or municipal services to outright demolition (Zaghalonl 1994). These are common phenomena in Lagos urban informal settlements.

Qualifying definitions, characteristics, quality and examples of informal settlements vary widely, with the inherent danger of generalization, but an attempt has been made to identify key features which are common to such areas and distinguish them. Generally, according to Kombe and Kreibich (2001) informal settlements portray some similar characteristics irrespective of their status or where they exist the following are their common characteristics:

- They are built by the inhabitants themselves and their proportion continues in spite of frequent eviction threats from public authorities. The houses are built with the intent of owner-occupation, renting or both.
- They are built, for the larger part, by low-income urban dwellers that the existing formal housing systems or markets are hardly realistic options.
- The houses are built primarily with informal financing methods, i.e. family savings, capital from inheritance, sales of inherited land or savings from informal credit associations.
- The builders employ local building materials, skills, designs and indigenous technology.
- Often builders do not adhere to formal/legal building codes and planning standards.
- The informally built houses exhibit high variations in types and quality of construction, ranging from traditional construction materials (e.g. mud and pole or thatch) to modern quality components (concrete blocks, corrugated iron, aluminum, zinc, or tin roofs).
- They are built and serviced incrementally, ensuring flexibility on the part of builders and owners.
- They can exhibit unique urban designs with significant variations in lay-outs and spatial arrangements.
- Their densities are normally increasing rapidly up to saturation or over densification stage.
- The land use patterns are highly mixed, including small industries and urban agriculture.
- Especially in the initial stage of growth social cohesion is strong

3.2 Evolution and Causes of informal Land use

The relationship among people, land, and shelter is complex and differs between nations depending on their history, culture and legal system (Eliade, 1957; Doebele, 1983; Rykwert, 1988; Payne, 1997). Even though some societies still operate under customary tenure systems, while most have regulated the ways in which land may be held as a result of both social and economic reasons (Payne, 1997). These systems, however, have led people who cannot conform to them to create extra-legal systems, thus abandoning the formal approaches to settlements (UNCHS/Habitat, 1982; De Soto, 1989). Informality of land use according to Macedo (2000) is not only as a result of massive rural-to-urban migration or the perception that urban areas offer a better quality of life, let alone the pull of the bright lights of the city. Informal land use is also a product of national and regional inequalities due to the changing economic nature of nations and the lack of appropriate policies to mitigate the effects of change.

The economic push and pull associated with these processes is related to employment and is affected by geographic, infrastructure and service factors. Significant economic push from rural areas can be attributed to the exclusion of small farmers from the agricultural economy by large landholders. With massive numbers of displaced small farmers relocating to urban core areas for access to wage employment, uncontrolled and unplanned urbanization was inevitable. The housing supply in urbanized areas was inadequate, and with the low wages these workers were earning, formal housing was not affordable; their only option was informal arrangement (Macedo, 2000).

The incidence of informal land use has also been credited to the inability of governments to provide affordable housing to low-income families, particularly in the largest urban centers of developing countries (Abrams, 1964; Turner, 1977). Therefore, a large proportion of urban people are forced to live in sub-standard, unhealthy conditions. Uncertain land tenure contributes to the insecurity and other difficulties of squatters. This situation as noted by Chung and Hill (2002) persist due to the failure of the urban housing and land markets, in particular: the high cost of housing construction; the high cost of formal land transaction; the lack of affordable credit to low and middle income families; the small amount of land available for urban housing, in part because of the slow pace of regularizing tenure; insufficient government, and other, funds to implement services; other restrictions on service provision; lack of alternative urban housing that is affordable for low-income households; and poor co-ordination of urban infrastructure planning issues within Government. Payne (1997) argues that what seems to be an inability of governments to control or regulate land through direct action may be a reflection of the strong demand for land as much as a lack of government commitment or capacity to act. For instance, Lagos state government having realized that the informal sector

accounts for between 75% to 80% of urban employment and plays important role in income generation, as contained in the Upgrading Policy Note of the Lagos Urban Renewal Authority, the State relaxed rigid regulatory rules, which lead to further intensification of informal land use. Rising costs and delays in executing formal land transactions have also been blamed for the proliferation of informal settlements in various cities including Lagos. Under some formal systems, the cost of transferring the rights of land exceeds the market value of the land itself (Dale, 1997). For lack of a better option, these settlers, often migrants in search of employment and better living conditions, occupy vacant land, public or private, and build shelter for themselves. The study conducted by Agbola and Agunbiade, 2006 in some selected informal settlement in Lagos metropolis revealed that the process of obtaining legal title is expensive and laborious which is actually out of the reach of poor majority. Therefore, they prefer to approach the informal sector in order to meet their land and housing needs.

Urbanization coupled with rigid and inadequate land administration and planning policies to meet ever increasing demands for housing by the poor majority has also been associated with the growing of the informal land use (Ali and Sulaiman, 2006). Lagos, like many developing cities has been experiencing the demographic phenomenon of urbanization which is one of the driving forces for the incidence of informal land use on the fringe of urban centres. Recent studies and surveys show that about 70 per cent of the urban population in Lagos lives in informal settlements.

3.3 Urban Land management

Land management is a broad term that refers to a set of processes that deal with the: acquisition of land, continued rights to the land, regulation of the use and development of land, and trading of land. Land is managed either formally or informally. According to Planact (2007) the formal systems are characterized by: legal, regulated channels managed by governmental authorities; a great deal of bureaucracy, delays, often high costs, and problems in dealing with issues that fall outside existing policies and regulations; system biased towards owners of land and property, but use of land and property can be regulated by government On the other hand, informal systems are characterized by: extra-legal channels that are mainly used by people with an immediate need for land, and who do not have the financial capacity to buy or rent through formal channels; a more flexible and responsive way to address people's needs, informal networks are often utilized for access to land and to address governance within communities; instability and lack of regulation, rights are less secure or not acknowledged at all by the formal system. In Lagos, both formal systems and informal systems happen simultaneously and within the same areas.

Generally land in and around urban areas are either owned by the government or by the private sector or owned communally by tribes or clans. Often large land owners, be they governmental, communal or private, have a vested interest in maintaining the position. These vested interests gain more by keeping the land management fragmented, without proper controls and by keeping the dealings in the land market non-transparent. While they profit from the position the prime losers are the urban residents, particularly urban poor who are mostly accommodated in the informal settlements. Problems in urban management have arisen mainly because of the inability of government to cope with the intensity and range of urban problems arising from rapid growth of population due as much to natural growth as to migration (Dattatri, 1994). Government has been quiet observer to the deteriorating infrastructure and resulting poor environmental conditions within their area but also chaotic and environmentally unsound land development in the periphery.

In the recent past there has been a clear recognition of the importance of urban land management in helping to alleviate urban poverty and urban livability in the developing countries. It is argued that, managing the economic aspects of urban poverty has to aim at reforming regulations and policies that limit the access of the poor to urban land (Olima 1997). Despite the fact that land has been recognised as the main link between development programmes and projects and people little importance is shown for sound urban land management. The result of this according to Dattatri, (1994) is seen in a continuous increase of land prices leading to land speculation, scarcity of developed urban land particularly for housing, and proliferation of slums and informal settlements with little or no infrastructure services. For urban land to meet the needs of a growing population it has resulted in conversion of marginal or environmentally hazardous lands such as beside railway tracks, along rivers and canals, swamps to accommodation by this ever increasing population.

3.4 Extent of informal settlements in Lagos

In Lagos, the rapid growth of informal settlements was part of unprecedented urbanization process fueled majorly by rural-urban migration. The growth in city population occasioned increase in the demand for urban land for different purposes. The increase in demand was accompanied by increases in land prices, rental prices, inadequate formal land supply and poverty. The influx of population from outside the city coupled with reduction in the affordable housing provision especially from formal sector created an acute housing shortage and price increased beyond the reach of the poor majority. With this, the poor are left with no option than to occupy any available land especially outside the formal system which are mostly located in vulnerable areas of the city. Vacant uncommitted and committed government lands were also victims of this process. In a way informal land occupation is a spatial manifestation of poverty. Currently, Lagos urban agglomeration is characterized by a very significant presence of the urban poor who are mostly accommodated in informal settlements, with a growing poverty profile.

Informal settlements have multiplied over the years and the living condition of the poor is getting worse. Environmental decline, inadequate basic services and infrastructure in informal settlements across the state hit the poor hardest. Informal settlements which range in size from clusters of shacks to entire districts are scattered across the state in different local government. The number of informal settlements and the population in Lagos Metropolis are increasing at a faster pace on daily basis. As far back as 1984, 42 settlements had been identified as blighted (UNCHS/Lagos State Government). The number has risen to about 100 as at 2004 (UN-Habitat/Lagos State Government). The study carried out by Nubi and Omirin in 2006 revealed that over 70% of the built up area of the Lagos metropolis is blighted. Although, presently there is no accurate data on the exact number of such settlements and their population but there are indications that there are over 200 of such settlement in the state.

It has been observed that informal settlements in Lagos are located on both private and government lands without access to basic services. The poor in the city of Lagos are spread in squatters and informal settlements located in vulnerable areas such as swamp, canal setback, rail line setback, marginal land among others, deprived of basic infrastructural services. These make them more vulnerable to environmental degradation, threats of eviction, ejection and demolition.

4 CHALLENGES OF INFORMAL LAND USE AND ATTAINMENT OF HEALTHY CITY IN LAGOS

Informal land use system have evolved in response to a need for alternative means of access to land and shelter for the urban poor. Such systems provide alternative land delivery and tenure through simplified procedures that are accessible, user friendly and affordable. Up to 80% of all urban land delivery in developing countries is through informal means (UN/FIG, 1996b). However, the growth of this land use is associated with various socio-economic, land and environmental related problems. These consequences according to Ali and Sulaiman (2006) include pollution, deforestation, flooding, and waste of agricultural lands among others.

Informal land development presents a number of challenges to urban land management process as well as urban dwellers. Where the informal land tenure systems are not recognised by the authorities, they do not provide sufficient tenure security to residents of informal settlements (UNHSP, 2003a; UNHSP, 2004a; UNHSP, 2004b). Since they are not part of the official urban management system, little or no land information is collected in the settlements and they are left out of the urban development planning process (Sliuzas, 2004; UNHSP, 2002). Yet these settlements are home to increasingly large proportions of urban populations in developing countries.

The informal occupation of land by poor migrants and otherwise displaced families creates one of the biggest challenges to urbanization. Even when the land becomes subject to regularization, it is almost impossible to make the area comply with established land use and zoning standards, especially when the settlements are already consolidated. Informal developments are the alternative for those too poor to participate in the formal market of planned and serviced housing. The manner in which these settlements materialize is similar across the majority of cities in developing countries with no exemption of Lagos.

Furthermore, lack of access is also a common problems associated with informal land use. Because there is neither a layout plans nor the regulatory machinery, residents tend to build to almost 100 per cent of their

plot size. It has become impossible to provide access roads to these areas as there is no space to accommodate such. Likewise, no area is left open for social services like schools, hospitals, children's play grounds, etc. Consequently, people and services movement in these areas are very restricted and residents have to walk long distance to obtain services like health, education, transport and the like (Ali and Muhammad, 2006). The rapid growth of informal land use in the urban areas of Lagos poses significant challenges to both dwellers and government. Challenges of informal land development in Lagos is multi dimensional ranging from social, economic, cultural, environmental and physical dimensions.

Informal land use is a widespread phenomenon in Lagos with the dwellers occupying land outside the legal land tenure system whether through the occupation of land in the periphery as illegal subdivisions by private agents, the direct invasion of public lands by settlers, or the invasion of infill vacant public lands in central areas with limited or no access to public utilities. Lagos urban informal settlements are characterized by a very significant presence of the urban poor, with a growing poverty profile. Informal settlements have multiplied over the years and the living conditions of the poor are getting worse. Environmental decline, inadequate basic services and infrastructures in these settlements across the state hit the poor hardest. Informal development which range in size from clusters of shacks to entire districts are scattered across Lagos state in different local government. The number of informal settlements and informal settlement population in Lagos Metropolis are increasing at a faster pace on daily basis. From 42 slum settlements in 1984 (UNCHS/Lagos State Government), the number has risen to about 100 (UN-Habitat/Lagos State Government, 2004). The continuous expansion of these settlements without adequate caution poses health, environmental, planning and development control problems to policy makers and the inhabitants.

The urban challenges of developing countries as identified by Population Reference Bureau in 2004 include environmental hazards, natural disasters, public and reproductive health, and poverty. These are all evident in the various pockets of informal settlements located across the state.

The environment components such as land, water and air which provide support system for healthy living, prosperous city and liveable city are been polluted daily in Lagos as a result of pressure on them due to human developmental activities and desire to meet daily livelihood especially by the poor. According to Gandy (2006) the city's sewerage network is virtually non-existent and at least two-thirds of childhood disease is attributable to inadequate access to safe drinking water. In heavy rains, over half of the city's dwellings suffer from routine flooding and a third of households must contend with knee-deep water within their homes. With this situation, the poor are mostly affected because they often live in marginal or environmentally hazardous and ecologically vulnerable areas of the city.

The influx of population coupled with infiltration of informal land use and unplanned growth has serious implication for flooding wish has been identified as a serious problem in Lagos metropolis. The poor drainage systems, the relatively high water table and the flat topography of Lagos had hindered the flow of surface water run-off and prevent rapid discharge into the sea. Flooding of Lagos metropolis is usually caused by a combination of human and natural factors. The human factors are as a result of poor wastewater disposal and other sanitation practices (e.g. blocked drains by refuse, silt, sludge, etc) which are common practices in informal settlements. The natural factors include rainfall, flat topography and poor infiltration. Informal settlements often occupy marginal land, including river banks, swamp and flood-plains. Some are regularly flooded even in moderately heavy rain. This has caused a lot of damages which have led to lost of lives, properties, and destruction of infrastructural facilities.
Furthermore, informal development suffers from uncontrolled land use, squatters, overcrowding, poor drainage, unplanned access, and lack of adequate sanitation facilities and water supply. In adequate or conspicuous absent of these basic facilities make daily life uncomfortable to the inhabitants of these settlements. Lagos, the commercial nerve center of the Nigeria, also faces the difficult problem of informal land development within its cities. The continuous rise in incidence of informal land use, reduction in infrastructural provision, insecurity of tenure, poverty and continuously worsening environmental conditions in these areas make it very difficult for the dwellers to improve their homes and immediate environments on their own.

The informal occupation of land generates problems of marginality, exclusion and vulnerability for the settlers. Although the inhabitants especially those located in the central areas benefit from living in a central area accessible to employment, infrastructure, and urban services (especially health and education) however,

living conditions are extremely poor (Magalhaes and Eduardo 2008). Low quality houses and the dire environmental conditions of the land they occupy expose these settlers to higher than average health risks. These areas are devoid of open spaces and recreation, as well as inadequate circulation and access to the residential units, making services such as emergency provisions and garbage collection extremely difficult. These situations are evident in most informal settlements in Lagos metropolis notable among these are – Ajegunle, Makoko, Ilaje, Iwaya, Ijora among others. Livability, safety, sustainability and health of these settlements and their dwellers become a mirage if nothing concrete is done to address the current situation.

According to Hancock and Duhl (1988) a healthy city is one which is continually creating and improving those physical and social environments and expanding those community recourses which enable people to mutually support each other in performing all the functions of life and in developing to their maximum potential. Therefore, healthy is defined by a process and not by outcome. A healthy city is not one that has achieved a particular healthy status. Rather, it is one that is conscious of health and striving to improve it (Tsouros 1990).

However, for a city to be healthy according to Tsouros (1990) it must possess the following qualities:

- A clean, safe physical environment of high quality which include housing quality
- An eco system that is stable now and sustained in the long term
- A strong, mutually supportive and non-exploitative community
- A high degree of participation and control by the public over the decisions affecting their lives, health and well-being
- The meeting of basic needs (food, water, income, work, safety) for all the city dwellers
- Access to wide variety of experiences, resources, contacts, interaction and communication
- A diverse, vital and innovative city economy
- The encouragement of connectedness with the past, with the cultural and biological heritage of city dwellers and with other groups and individuals
- An optimum level of appropriate public health and sick care services accessible to all
- High health status and low levels of diseases

An appraisal of the above qualities suggests that it is an ambitious goal to achieve especially in informal settlements which are characterised by low quality housing, inequalities, vulnerability, lack of access to public infrastructural facilities, exclusion, and inability to meet basic needs of life among others. However, in the other hand, it is an achievable goal bearing in mind that healthy city is a learning, evolving and continuous process which no one city could lay claim to have totally achieved. This means that there must be continuous efforts to see that the inherent characteristics of the informal settlements are turned around.

Unhealthy living, urban and environmental problems of cities in developing countries have been attributed to uncontrolled and excessive population growth, lack of land available for urban development especially by the low-income group as well as inadequate infrastructural facilities which are caused by lack of resources, corruption, poor maintenance culture or deliberate neglect by the government (Giroult,).

5 CONFRONTING THE CHALLENGES OF INFORMAL LAND USE AND ACHIEVING HEALTHY CITY IN LAGOS

There is a need for city wide informal settlements regularization in Lagos. The pocket of informal settlement scatter across the state should be considered for regularization. Many approaches for regularization have been tried in different parts of the worlds with high degree of success. Such approaches include titling, legalization and/or formalization of tenure and physical upgrading of informal settlements. These approaches usually aim to forge links between the formal and informal land management systems. However, regularization processes often require legal, administrative and/or technical adjustments to the formal land administration system. It is important to note that globally, national land policy approaches to informal settlements are generally shifting from policies that threaten tenure security (e.g. eviction, neglect, involuntary resettlement) to positive policies that support regularization of these settlements.

It is suggested that policy framework and strategy for an improved urban land administration be instituted. There is urgent need to formulate and implement both an appropriate and efficient land administration system as well as modernization of land information system. Formulating or implementing an urban land tenure policy should not be isolated from other related policies of urban land management and city development. Tenure should be seen as part of a package of policy measures intended to improve the efficient and equitable use of urban lands and, at the same time, improve the living conditions of the urban poor. The tenure options should naturally encourage the people to invest their own labor and savings in the improvement of their environmental conditions. Furthermore, it is also important to offer a range of tenure options, including ownership and rental options, so as to meet the diverse and changing needs of communities and households on a long term basis.

It has been established from literature that shortage of affordable housing and inadequate land supply through formal system especially for the urban poor is a major cause of continous incidence of informal land use which has become almost intractable in Lagos. Therefore, government needs to develop a comprehensive Urban Growth and Housing Strategy with timeframe and specific measurable targets to addressing the shortage of affordable and adequately serviced housing.

Lack of adequate or at times completely absence of basic infrastructural facilities is a major feature of informal settlements and constitutes a serious health challenge for the dwellers. This shortage could be as a result of deliberate attempt by government not to recognize these categories of settlements since they are outside the legal provision. Also, limited resources at the disposal of government and concentration of these limited resources on the recognised settlements at the expense of the so called illegal settlements could be another reason for such neglect. Thus, consideration needs to be given to alternative ways to provide basic services to poor households in the informal settlements, particularly ways that encourage environmentally sustainable and self-sufficiency. Private sector (NGO, corporate bodies) option can be explored to provide assistance to the settlements in order to bridge the gap between what the government can provide and what the residents need for decent and healthy living. However, it is important to say that the private bodies should be encouraged through duty and VAT exemptions or rebate for providing such services.

6 CONCLUSION

Land defines the social, economic and political relations in the society. While access to land use in most developing countries could either be through formal or informal system but the informal system has been seen as the major provider of land especially for the majority of urban poor. The paper has discussed extensively the issues and challenges of incidence of informal land development and how it can be confronted in Lagos. The paper revealed that the incidence of informal land use is rooted in uncontrolled and unplanned urbanization, inability of government or the formal sector to provide affordable housing to the low-income group, inappropriate land administration and planning policies to meet housing and land demand of the poor majority and poverty among others. The findings revealed further that Challenges confronting informal land development in Lagos is multi dimensional ranging from social, economic, cultural, environmental and physical dimensions. Therefore, the paper suggests the need to confront this situation through adequate and sustainable urban land use management system. Finally, the prevention of new informal settlement is critical to the sustainability of the solutions proffered. This requires an adequate institutional and legal framework for land development regulation that facilitates the production of affordable housing and land for all uses, thus reducing the informal occupation of land and adding an important institutional development dimension to sustainable and healthy urban development.

Contemporary tools of urban development - orientated on equity?

Katja Stock, Lidewij Tummers

(Dipl.-Ing. Katja Stock, Leibniz Universität Hannover, k.stock@igt-arch.uni-hannover.de)
(Lidewij Tummers Ir. L.C., Delft University of Technology, L.C.Tummers@tudelft.nl)

1 ABSTRACT

Equity planners are convinced, "that equity in the social, economic, and political relationships among people is a requisite condition for a just and lasting society" (Krumholz/Forester 1990:51) and that politics do not only serve authority interests, but also potentially compensatory equity (Bauhardt 2003:41). In this paper we explore if there are criteria to indentify equity planning in planning processes. We try to find a role model for equity planning by analysing three actual planning processes for urban renewal, with different legal status and different planning instruments, all concentrated on complex social and spatial situations.

In each of our case-studies, a specific planning entity with a set of rules was created. In order to understand if these could be a role model for similar urban locations, we compare the local conditions as well as the planning processes. To investigate if the local inhabitants have benefitted from the development in similar and more or less fair ways we apply criteria developed in gender mainstreaming for spatial planning.

On the one hand we raise the question if we can find elements of equity planning in this processes, and how targeted to the real situation the used tools and institutions have been. On the other hand, we look in how far social objectives have been met. We conclude by signalling the potential for embedding equity planning in urban renewal. We did not, however, find a role-model, as the equity results for local residents have mainly depended on specifically created planning instruments and exceptional social budgets.

2 SEARCHING FOR A ROLE MODEL FOR EQUITY PLANNING

We want to concentrate on equity planning as both a participatory way of searching for social goals, as well as a method to bring it to spatial reality. In contrast to democratic planning, which is mainly orientated on the participatory process, the equity planning focus is on the substance of the program (Fainstein/Fainstein 1996:270). Adjusting power asymmetry between the stakeholders is the objective of equity planning (Bauhardt 2003:40). It stands for "the new movement for urban change that calls for greater representation of disadvantaged groups in the governmental process and for the decentralization of governmental policy making" (Fainstein/Fainstein 1996:271).

This movement has gained relevance for German planning practice with the end of the confrontation of eastern and western blocks at the end of the last millennium, symbolized the fall of the Berliner Mauer. The position of citizens' initiatives and grass root groups in Germany changed: instead of confrontation & opposition-based, the planning culture shifted to a more negotiative model. Herewith a new development in spatial planning was needed (Bauhardt 2004:149) enlarging possibilities to articulate the divergent interests of different target groups. Authoritarian appearance and the technocratic way of planning, which existed mainly in the 1980's, lost importance (ibid.).

Historically the traditional planning proceeding was orientated at middle- and upper-class assumptions of urban organization (Fainstein/Fainstein 1996:267ff). Against this background, concepts of more social-democratic and liberal ideas like democratic-, equity- and incremental planning, are up and coming. These approaches, like any planning approach, are following the changing political thoughts and are to be seen also as political processes (Fainstein/Fainstein 1996:266). In this paper we focuss on three different urban renewal projects, characterized by the contemporary discourse of social justice and resilient city. In this framework the spatial planning is related to a wider programme of finance and social activities:

- Hannover-Vahrenheide: Soziale Stadt
- Rotterdam-Pendrecht: Integrale Stedelijke Vernieuwing
- Hamburg-Wilhelmsberg: International Building Exhibition IBA

We raise the question in how far equity goals are embedded in the basic planning elements applied.

After introducing some facts and figures about the three examples explaining the general spatial and social situation, we want to look for some elements of equity planning in these projects.

3 EXAMPLES OF CONTEMPORARY URBAN DEVELOPMENT PROJECTS

In three case studies we want to identify if there are any elements of equity planning to be found. These projects present current urban development processes. Each of them is using different instruments for promoting similar goals: spatial, social and economic development combined with ideas of sustainability.

The schedule below shows some comparable information about their organisational structure:

	Hannover - Vahrenheide	**Rotterdam - Pendrecht**	**Hamburg - Wilhelmsburg**
Program	Soziale Stadt (Federal program)	ISV - Integrale Stads Vernieuwing (National Law)	IBA - Internationale Bauausstellung (Regional activity)
Process term	1998 - 2010	1995 - 2009	2007 - 2013
Budget	1998-2008 15 Mio € Since 2001 3 Mio € (esp. for education, youth, local economy)	ISV PM Social Ca. 3,5 Mio €	100 Mio €
Investment	52 Mio € (Renovation) · 7,5 Mio € National Renovation Budget · 17 Mio € property sales	PM	120 Mio € (Infrastructure)
Unit of organisation	Stadtteilbüro / district agency	Working group, managed by local authorities, steered by housing corporation (main investor)	International Building Exhibition IBA Hamburg GmbH
Cause for planning	· Bad housing condition · Social problems · negative image of the district	· deteriorating housing conditions · aging population and entrance of immigrants · negative image of the district	· Development pressure · Social problems · negative image of the district
Development objectives	· Improve the situation of poverty and failing housing standards · Stabilizing social structure · Improve economical opportunities for residents	· Reduce the percentage of social housing from 95% to 54% · Make public space more safe, recently expanded to also reduce violence in the home · Improve the image of the neighborhood · Improve level of local services especially for senior citizens	· Housing · Innovative building types · Saving and producing renewable energy · Qualify education · Promote of art and culture, working places, leisure activities · Enhance transport
Principal actor	· GBH housing corporation	OWG housing corporation	IBA team
Partners	Stadtteilforum, local authorities	with local authorities and private investors	· International Garden Show igs 2013
Committees and boards	· Refurbishment committee · Stadtteilforum	· Working group · Indepartmental public servants meeting · Project teams · Dwellers organization BOP	· Supervisory board · Curatorship · Participation council · Institutionalized dialogue with citizens

3.1 Soziale Stadt Vahrenheide-Ost

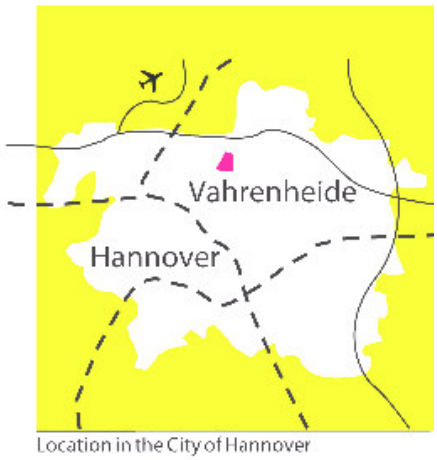
Characteristics		
Total space	73 ha	
Total population (01/2009)	+/-7.000 pers.	(100 %)
with foreign background	3.612 pers.	(51,6 %)
under 18 years	1.505 pers.	(21,5 %)
over 60 years	1.757 pers.	(25,1 %)
unemployment	20,4 % of pot. empl.	
Housing stock	3.400 units	(100 %)
in public authority	ca. 1220 units	(59,4 %)
Public transport	City railway 3	Stops / 1 Line
	Busses several	Lines

Vahrenheide-Ost was build between 1955-1974 as the first major residential area in Niedersachsen. Following the urban design principles of the time, most of the buildings consist of apartment blocks with larger green spaces in-between. It contains a number of schools and Kindergarten, 2 churches, as well as services and 2 small shopping centers.

In the first stage, a highrise block from the 1970s with 560 apartments (of which 50% empty > 1 year) and accumulating huge social problematic was torn down. On the plot so far 30 one-family houses have been build, more are planned but building stagnated in the financial crisis.

Through the Stadtteilforum, local residents participate in the decision-making and articulate their needs and aspirations. It decided on funding local initiatives from a yearly €25.000 Local Development Fund

Building structure



Location in the City of Hannover

Urban scheme

Open space with rainwater retention

Tenant Club Mik Y

3.2 Integrale herstructurering Pendrecht

Characteristics		
Total space	123 ha	
Total population (01/2009)	+/-12.000 pers.	(100 %)
with foreign background	6.600 pers.	(55 %)
under 19 years	3.120 pers.	(26 %)
over 65 years	1.740 pers.	(14,5 %)
unemployment	20,6 % of pot. empl.	
Housing stock	6.400 units	(100 %)
social housing	5.120 units	(80 %)
Public transport	Metro 1 Stop / 1 Line Busses 2 Lines	

Pendrecht was build as exemplary CIAM residential area: apartment blocks and terrace houses around large public green spaces. However, since 1980s the social position of its residents has been declining, and Pendrecht became one of the first areas in the ISV programme. [note: Integrale Stads Vernieuwing was a national programme by which cities could apply for subsidies if they fulfilled requirements such as social investments, citizen participation in design process, integrat ing design of green space, traffic, networks and so on).

Since 1995 a programme of neigbourhood development has be implemented, subsidized mainly by ISV law.

Nevertheless, in 2009 Pendrecht was listed second in the "problem neighbourhood list " of the Dutch Ministry of Hous ing.

Location in the City of Hamburg

Overleaping the Elbe - Urban development in the south of Hamburg

The landscape of the Elbe Island Wilhelmsburg is affected by a mixture of water and meadows, one family houses and perimeter blocks in wilhelminian style, harbour industry, railroads and highways.

This is the suspenseful background of the International Building Exhibition IBA Hamburg from 2007 until 2013. A team of planners and experts for energetic engeneering, education, art and public relation is hired by the City of Hamburg to proof and develop about 40 projects under the three keythemes Cities and Climate Change, Metrozones (development of the inner peripheries) and Cosmopolis (organising cultural exchange).

4 COMPARING THE MAIN FEATURES

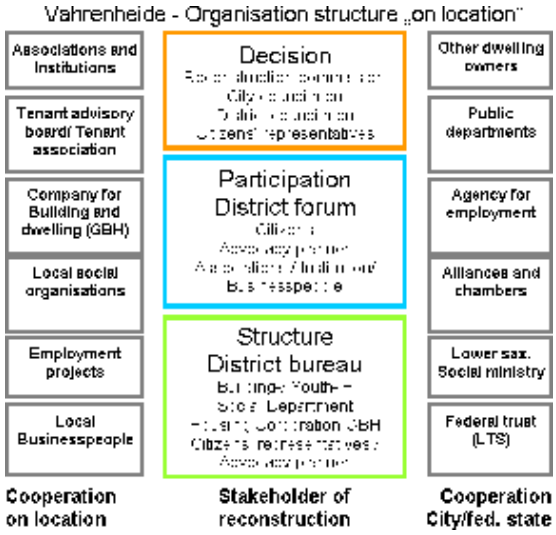
4.1 Organization

Vahrenheide

The central coordination point for the reconstruction is the district bureau. Representatives of public departments, housing corporation, citizens and advocacy planners are meeting and working here together.

Within the scope of the citizens' district forum the goals of the renewal are to be discussed. The result has to be reported to the reconstruction commission which frames a recommendation for political decision-making in the district council.

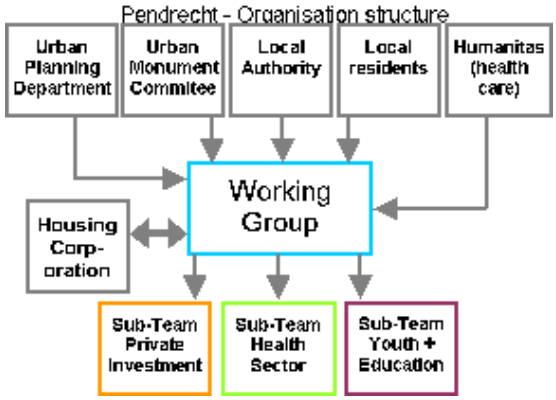
The local public housing corporation participates at local events and meetings and works together with urban and social planners and advocacy planners in the district bureau. (Landeshauptstadt Hannover 2008:13ff)



Pendrecht

The renewal process was an initiative of the housing corporation who owned 85% of the housing stock. They had to work together with the planning department of the municipality who is the owner of the land and controls building permission. Together they developed a new zoning plan, respecting the principles of the original design.

A working group was created, including representatives of local residents and following demands of ISV-law. For partial projects sub-teams were formed with wider collaboration, for example the health sector, youth and education, green structure and open spaces or private investors.



IBA Hamburg

The IBA Hamburg is a full-owned subsidiary of the City of Hamburg in form of a German GmbH (Limited Company). With the International Garden Show igs 2013 it has an associated company which is also located in Wilhelmsburg. As shown in the right illustration the company is under observation of different kind of boards and councils, which are consulted in order to assure a high level of quality up to date.

The company staff consists of urban planners, (landscape-) architects and experts for real estate, for renewable energy, for public relations and for educational development.

Comparing the organization structures

All examples have more or less complex structures, including provisions for the participation of local residents. Through cooperation with experts for spatial, social and economic questions they try to achieve a

high quality standard. In the two german projects the decision making is located on the political level. In the Dutch situation the working group prepares overall decisionmaking such as investment programmes and zoning plans for the local council.

IBA Hamburg organisation structure
(based on IBA 2009:43)

IBA Supervisory Board 6 Representatives from the Senate	IBA Board of trustees 7 Global consultants for professional and scientific questions
IBA Hamburg GmbH (the same management as igs 2013)	igs 2013 GmbH (the same management as IBA Hamburg)
IBA/igs Participation Council (24 citizens and 9 politicians (without vote) who are consulting)	IBA Climate & Energy Council (6 experts from science, policy and praxis consulting)
IBA-Partner & Sponsors (over 80 representatives from the local business world)	

4.2 Instruments

Vahrenheide

As a pilot for the federal program “Soziale Stadt”, the renewal concept for Vahrenheide-Ost identifies enhancement of constructural, economic and social conditions as the main fields of action in the spatial development The planners focused on creating better housing conditions, with additional programmes for social moblization and ecology (introducing renewable energies). The social investments turned their attention especially on the aid for the youth, for families and elderly in disadvantaged living situation as well as on the promotion of the local economy and tried to create integrated solutions. (Landeshauptstadt Hannover 2008:16) Besides the renewal committee, the District Forum (Stadtteilforum) discusses general orientation of the investments and has e yearly budget of €25.000 to spend on local proyects and initiatives.

Pendrecht

ISV law is a national subsidy for urban renewal for which Municipalities can apply every five years. To obtain funding, plans and proposals need to fulfill specific conditions for ‘integrated planning’, such as participative design processes, and concerted planning of the green structure, housing, transport, infrastructure and so on. In other words all technical departments of the municipality were with more or less intensity participating in the working group. The application for ISV funding had to go through several rounds of decision-making, balancing local priorities, the quality of the proposal and the available national funds.

To participate in the planning process, the local residents were facilitated with a meeting place and consultancy budget to create a board which represented the residents in the working group. These support funds have been going down over the years, following a general trend in the Netherlands.

In the first years of development, guiding principles for planning were the rehousing of the aging population and preserving the qualities of the original urban and landscape structure. In a later stage, economic impulses came more to the foreground and new social funds were applied in a social investment programme called Pendrecht Zet Door (pendrecht perseveres). From that moment also ‚soft’ municipal department got involved in the working group, such as Employment (SoZaWe), Education (DSO) and health care (GGD). The working group is chaired by a so-called ‘City-officer’ (stadsmarinier) a highly qualified and mandated public servant. Since 2008, households have to show a secured minimum income to rent a corporation dwelling.

IBA Hamburg

The IBA was installed by the City of Hamburg by a special political senate decision in 2005 and proclaimed by the IBA memorandum which was called: Leap Over the Elbe (cf. Freie und Hansestadt Hamburg 2005).

The IBA Hamburg works as a project developer. The first tasks were verifying different kinds of project ideas and searching for investors and project running organisations. An overall project plan is used to promote the projects, but not as an interrelated master plan. The IBA Hamburg has no planning authority; reconciliation with local authorities is needed.

The IBA Hamburg works against the thematically background of three key themes:

Metrozones – How to develop inner-city border and crossover zones to multifunctional living spaces?

Cosmopolis – How to create the living together and the optimal use of potentials an international multicultural society? As well as **City in Climate Change** – How could metropoles reconcile economic and population growth with environment and climate protection?

Every IBA project has to fit in at least one of these key themes (IBA 2009: 27).

Comparing the instruments

The Pendrecht and Vahrenheide projects run within national programmes. They are focused on basic aims of creating better living conditions for disadvantaged social groups. They need to use integrated approaches to obtain funding from the national programmes, based on the assumption this is a better way to ensure durable success. The IBA Hamburg is more orientated on creating new and innovative 'fysical' results which should be role models for similar spatial situations. With postulating the key themes Metrozones, Cosmopolis and City in Climate Change they create the framework for integrated solutions. The IBA structure is a special approach with a lot more money than the other examples were able to obtain.

Vahrenheide is the only location where residents have direct say over a fund for local initiatives.

4.3 Results

Vahrenheide

New ways of creating property were promoted, for example self owned family houses or rental cooperatives. This was a contribution in the stabilization of the local social structure and in the enhancement of the citizens' relationship to the district (Landeshauptstadt Hannover 2008:15). The rental cooperative project was not successfull so the scheduled accommodations are currently again in rent. 29 family houses have been built. Buildings fields for ca. 40 houses are still offered. The City of Hanover surrendered a part of their occupancy rights for social rentals. Herewith mixture and stabilization of social groups is achieved. (Landeshauptstadt Hannover 2008:19ff) The goals for bettering the local economy were not achieved, because of the oppositional economic framework. The embedding of economy in the housing structure was only sporadically. Old economic buildings could not be reused; they will be replaced by green space. The foundation of the "Interessensgemeinschaft Vahrenheider Gewerbe", an economic association, was the solution for strengthened the existing local economy. (Landeshauptstadt Hannover 2008:23)

Pendrecht

Between 1999 and 2009 interventions in the northern half of the neighbourhood have been almost completed as far as housing is concerned. The program for renovation of schools is lagging behind.

Housing conditions for senior citizens have improved considerably, together with the level of services. There is a wider range of typologies such as private owenership and homes contining workspace. Social programmes such as Pendrecht University have had a positive impact on social cohesion, yet on the other hand the urban problematic of increased immigration, violence & poverty intensified, partly as a result of influx from other renewal areas. For this reason it was decided to take a more radical approach. The operational planning infrastructure has modified under the influence of privatization and merging of the housing corporation, growing further away from its local roots and involvement, as well as restructuring in local government. In 2009 a major demolition was started in the southern half. This means a change of strategy compared to earlier planning principles which where mainly geared toward preservation and renovation. Building works are to start in 2010; however the market for private housing is slowing down some of the projects.

IBA Hamburg

The planned building projects of IBA Hamburg are mainly public buildings (school center, office building for the Federal Planning Authority of Hamburg, S-Bahn-Station, floating office building for the IBA itself) and housing development. The main project is called "Wilhelmsburg Mitte" (Wilhelmsburg centre).[1] To

[1] This project contains four building areas for experimental building with smart materials, on a smart price level, on the water and with a flexible space on offer. It is the so called "Building exhibition in the building exhibition". It will be completed by a local energy combination. Located at the same area is the office building for the federal Urban

guarantee quality IBA used mainly the instrument of urban planning, open space planning and architectural competitions. Both established & famous as well as young architects were invited to participate.

There are also projects for improving the cultural life on the Elbe island Wilhelmsburg. IBA-Laboratories for discussion on current questions of spatial and environmental planning and curated art events (Kultursommer) take place on the more or less intellectual level. Open air concerts like the Dockville festival and events like the "Flusslicht" are popular amongst all citizens of Hamburg and its metropolitan region. The year 2010 will be used for interim presentation (Zwischenpräsentsationsjahr) with a program of visiting construction sites and reflecting theoretically the key themes.In 2013 the work of the IBA Hamburg Company should be finished, meaning all projects, even not completely built, should be on the run. The social networks on the Elbe Island and the connections to Hamburgs community should be strengthened.

Comparing the results

Because of the difficult situation on the housing markets the projects from Hanover and Rotterdam have problems with the marketing of their new dwelling efforts. Also the activities for creating new jobs and infrastructure are hindered, creating small businesses and shops nearby dwellings results difficult.

The housing market in Hamburg is under a higher pressure, but even here it is not easy to find investors. They are also careful with investing in districts with a negative image. The succsess of the IBA projects could not be finally evaluated because the process is running until 2013.

5 LOOKING FOR EQUITY PLANNING

How do we define criteria for equity planning?

Acting on the assumption that feminist thinking is always a try to overcome conservative and paternalistic structures, we apply gendered appraoches to planning. The structures to overcome a traditional and maybe technocratic way of acting are comparable to the intentions of equity planning. For this purpose we rely on gender mainstreaming approaches to identify some major principles for spatial planning as follows (Tummers/Wankievizc 2009):

Key-issues shared everywhere are:

- The lack of user centered planning/ user centered transport systems
- usability as general topic
- the invisibility of daily routines, time-space patterns (life style)
- representation and diversity

For example the invisibility of diverse, eg gender-specific time-space patterns produces planning solutions that make urban resources un-accessible for some groups while causing peaks and overburdening of infrastructure that could be avoided (Tummers 2007). Issues of security & fear facilities accessibility tend to re-shuffle priorities in the planning and design of public space/shared space as well as transport & mobility network.

We apply these insights to our cases as folllows:

5.1 Is the everyday life of the local people relevant for the planning?

Multifunctional districts fulfil the needs of everyday life. Here the ways between home and working place, between educational institutions and daily shopping are short. The requirements of working and family life can be balanced by everyone (Becker 1999:60).

Vahrenheide

We can say that the everyday life of the local people is mentioned in the planning process in Vahrenheide because a neighbourhood help with founding the VIZe (Vahrenheider Initiative Centre for family, leisure, education and profession) and clubs for tenants (Project example: "Mik-Y") were promoted. Also a special social program for people in complex living situation was created. Other projects were educational

Development and Environment Department. This major project is not leaded by the IBA Hamburg, but by the department itself.

programms for parents, for German language learning and for healthy balanced diet. All these projects were help for self-helping and they should better the integration in the local neighbourhood an in the (german) society. Efforts haven been made to keep the local shopping centres alive.

Pendrecht

The Pendrecht project has also paid attention to solutions for the everyday life of the residents. The approaches are orientated on the local target groups. For example there are more services offered for senior citizens (a large share of the population). Houses with workspace are built to attract (after some difficulty) new kind of business and household types. And a new concept of school routing for children is established (Kindlint). However the smaller shopping malls are disappearing and a durable replacement has not been found yet.

IBA Hamburg

With enlarging the dwelling spaces in old standard houses the IBA Hamburg tries to enhance everyday life for immigrant families with many children. In this way the housing situation will be adjusted to the real family sizes (Project example: “Weltquartier”). However, during this enlarging the families who are currently living there have to move to other dwellings (including to other districts). They loose their neighbourhood and their well known environment for at least three years. The planners count with less back coming families because they have planned less dweling units than before.

With creating a better school structure and image the pupils should get better conditions every day and higher chances in the future (Project example: School centre “Tor zur Welt”).

The intentions of safeguarding local supply facilities for the resident population in the Quarter Veddel are not successful because of current economic framework and complex planning laws. The inhabitants will have to accept long distances to fullfill their everyday needs ever more.

Every project has positive examples in their single project portfolio, but there are also tendencies of not fulfilling some needs because of law destrictions or because of unsuccessful economic measures.

5.2 Is there diversity in staff at all levels?

Every planner has a subjective influence on the planning because of his/her undiscussed everyday knowledge and moral attitude (Bauhardt 2004:172, Greed 1994). To avoid involuntary advantage for any specific social group, we have to assure that the staff which designs, disposes and arranges spatial decisions, is diverse. (For more criteria for professional planning cf. Gender Kompass Planung (Zibell et al. n.d.))

Vahrenheide

In the project documentation (cf. Landeshauptstadt Hannover 2008) no special differentiation is made to show how the staff is exactly composed. The authors of the documentation are mainly female so we can conclude that they are generally the professional majority. Their cultural and religious background, their nationality and their age is not mentioned, but all of them wear German-sounding names. One goal explicitly articulated is to use gender mainstreaming concepts in every project (Landeshauptstadt Hannover 2008:17).

Pendrecht

The director of the housing company decided to invite young female architects for the new housing projects in the northern part (phase 1), because he expected a higher quality. This was a successful strategy; some of the projects have won quality prices. If it serves as an example of enriching the diversity in Pendrecht spatial planning is relative: gender mainstreaming is not structurally embedded. Some established (all male) offices were already involved for renovation- and key building projects.

The housing company is more actively trying to represent the diversity of clients in its own staff; on the other hand the municipality of Rotterdam is not pro-actively implementing this policy.

The fenomenon that immigrant dwellers are more seen as problem than as co-makers (with exceptional projects) is another structural problem, which is illustrated in their under representation in planning teams and working groups.

IBA Hamburg

The IBA Hamburgs staff is equal mixed from the gender perspective at the middle hierarchy levels, but the management is not. The supervisory board is led by a female senator. Also the age of the staff group is very mixed in all of the few hierarchy levels. However there are no staff members with a foreign background. There is no person who is specifically responsible for equal opportunities or gender mainstreaming.

Representatives of foreign economist take part in the participation council and meetings of local economists with IBA Hamburg management (AG Wirtschaft) so that they can point out their needs.

On the spatial level with the organizing of architectural competitions there is always the will to give young professionals a chance to participate.

To create a staff with a diverse mixture in perspectives of gender, age or cultural background is not easy even if it is subject to explicit policy (Burgess, 2008). This was not the case in the three main organisations of our examples. Although the Social City defines Gender Mainstreaming a policy aspect this is applied only to external activities. As a consequence, firstly population groups with an immigrant background are missing at all levels, and secondly women are under-represented in key- decisionmaking.

5.3 Does the planning enhance economic perspectives for all cultural backgrounds and age groups?

For independent and self-determined living there need to be possibilities to work and earn one's own income. Not only is this a need and right for every individual disregarding gender, ethnicity or abilities; the labour market increasingly needs everyone in the aging European societies. What has been achieved on this field in our case-areas?

Vahrenheide

In the Vahrenheide project the enhancement of the residents' economic perspective consisted of help for employment applications and local initiatives for further education. Unfortunately bringing jobs was not very successful, because of the general economic framework (s. 4.3).

Since Vahrenheide is a pilot for the federal program „Soziale Stadt" and not an official part of the programme area, there is no continuing special employment sponsoring. The local interest in entrepreneural promotion has not been identified.

Pendrecht

There have been attempts to bring or keep jobs within the planning process in Pendrecht but this was overrun partly by financial crisis and intensification of the problematic of poverty and unemployment in general.

A café run by mentally handicapped young people was started as a pilot project. The Pendrecht University collaborates with the renewal project to increase citizens participation and to help improve chances on the labour market. This is done through organizing mutual support as well as courses for the residents.

Another spatial project was building homes with workspaces/studios to improve diversity of use in the quarter. There are attempts to existing revitalize the original shopping centre with local and cultural entrepreneurs. The central shopping centre was revitalized amongst others by rehousing the supermarket to attract other business and services.

IBA Hamburg

The IBA Hamburg will provide new spaces for arts and crafts studios, with the aim to attract new groups of citizens to settle in the IBA area. At the same time, it should accomodate young people who experience problems on the labour market (Project example: "Kreatives Zentrum Veringhöfe"). An already existing project supported by local designers and economist aims to increase independent income for women with a foreign background (Project example: "Made auf Veddel"). They also support local entrepreneurs with small companies by creating new, affordable industry accomodations for a better spatial situation (Project example: "Welt-Gewerbehof"). Several new housingprojects integrate working space in the homes with the goal to reconcile family life and work (Project example: "Neue Hamburger Terrassen").

In all renewal processes, important pre-conditions are created for access to labour market and local economy. Despite these efforts it becomes clear that the local spatial and social interventions could't turn all problematic trends. In the comparison of economic enhancement, the favourable market situation in

Hamburg as well as the effect of a greater project area stands out. Within the small structures of the other two projects it is much more difficult to react to the general critical economic situation.

5.4 Are there planning criteria for accessibility and safety of public space and transport?

To ensure that open spaces and parks are attractive for the potential users and that public transport will be used be the inhabitants they have to be (and feel) safe and accessible. Safety is a subjective experience that varies amongst user groups. One of the main responsibilities for open space- and transport planners is to apply a diverse set of planning criteria. After design, the quality needs to be garanteed by maintainance.

Vahrenheide

In Vahrenheide different approaches for enhancing accessibility and safety of open spaces have been applied. They resulted in high quality green areas, and the open space usage is sophisticated. Accessibility and mobility for vulnerable groups has improved, for example: the heighth of the curbs in the whole quarter was reduced for people with limited mobility. More benches at crossroads for giving the possibility to rest were installed. And a reduction of street width for children crossing is realised. The tramstop was provided with a ramp as part of the general policy of the transport company.

Pendrecht

Pendrecht was already very accessable by public transport, and its quality is improving because of a city-wide programme for safety in public space. The same can be said for the 'schoon heel veilig' [clean, intact, safe] programme of monitoring and maintaining open space and streets. Safety is an important criterium for the Rotterdam Planning department, not just taking place in Pendrecht. However some plans are more successful than others. For the specific urban structure in Pendrecht, new solutions for public space have been sought, partly aiming to better articulate the difference between green for private and public use. Recently, Pendrecht has implemented a so-called 'Kindlint' i.e. a safe route for children connecting relevant destinations such as home, school, playground, library etc.

IBA Hamburg

Creating a save and accessible open space for the citizens lays mainly in the hands of international garden show igs 2013. After the Exhibition from April to October 2013 the renewed park will be open for the public. Other types of open spaces are created with the participation of the located citizens in order to fit their needs of safety and accessibility. (Project example: "Weimarer Platz")

IBA Hamburg has no authority in transport planning but tries to play a consultant role. Because of complex plans for the relocation of federal motorways, there are many citizens who demonstrate against this transport projects. The IBA as a stakeholder stands between the two positions. A major obstacle is the access to the northern S-Bahn station, which is not barrier free (Deutsche Bahn AG is owner and responsible). The main busses and the S-Bahn have a short interval (5-7 min) and the southern S-Bahn station will be renewed on the basis of an IBA competition.

In each of the projects we can find planning criteria to improve accessability and safty of open space and public transport, with in a very different level of scale. Since the responsabilities in this field are mostly in the hands of the public planners, there are more possibilities for participation and decision-making. Pendrecht and Vahrenheide have a similar urban structure with much open space and departed from a same problematic of changing use and lacking maintenance. While Pendrecht has chosen to partly privatise green areas, planners in Vahrenheide have implemented more ecological measures. In Vahrenheide very punctural interventions take place. Pendrecht makes use of existing city planning criteria. In the IBA area an additional organisation for creating innovative public spaces for everyone after 2013 was created.

6 CONCLUSION

We understand planning proceedings as political processes (cf. Fainstein/Fainstein 1996:282ff). Therefore we started from the standpoint that when politics aren't only to serve authority interests, but also potential compensatory equity (s. §2), this has to be rooted in planning processes.

In the paper, three different planning processes were introduced. The common feature consists of a complex spatial- and social planning area. Vahrenheide as well as Pendrecht come along with bad housing conditions and a negative social image. This was also a problem in Wilhelmsburg, but there also a strong pressure on

the rental market exists. Against this background we expected that planning and renewal in these areas are difficult and had to be very cooperative. We expected a high level of participation, as for reaching the goals of spatial and social enhancement, teamwork with the local stakeholders was needed.

In every process we found instutionalised ways of information and participation. Mostly they are more or less consultant, or related to the Arnstein 'ladder of participation' the level is still mostly oriented to "tokenism". The residents have the possibility to hear and to be heard, but there is no power to insure that their views will be heeded (Arnstein 1969: 216ff). The budget for the Stadtteilforum in Vahrenheide is a positive exeption.

More principles of equity planning can be found in the choice of the local projects, for example activities for education, employment, better housing conditions and upgrading the urban environment.

In the Vahrenheide case there was no longterm strategic concept of development. This had a negative effect on a major planning decision: in order to finance improvement of public space, apply sustainable energy and invest in social development, several blocks of Social housing units were sold to a private investor. With this the public housing corporation lost the power to create livable housing and living conditions for low income households. In Pendrecht, the corporation had a clear strategy of selling to home-owners, or on condition of renovating or upgrating the housing conditions. Due to the working group model to create the Masterplan (2004) the original urban structure could largely be saved as well as qualities in public space and transport, and for the existing architecture. However, contrary to Vahrenheide the implementation of social fonds was started later than the spatial planning process. Stabilisation, participation and social mixture was harder to achieve.

In the example of IBA Hamburg, the prestige object amongst our three cases, mainly the small projects are equity orientated. Typically, the main project of the IBA Hamburg: "Wilhelmsburg Mitte" is not mentioned in §5. IBA Hamburg needs its attracting activities to create a unique selling position, since it is not a part of a federal renewal campaign like "Soziale Stadt".

IBA Hamburg postulates that it is not an exhibition as expected but an urban development process integrated in the movements of Wilhelmsburgs society. At the same time it has to be a role model in themes like innovative building, climate change or creation of new concepts dor work- and living spaces. That is the very reason why IBA is choosen as a planning instrument. The image of a disadvantaged district should be improved by flagship projects. The Pendrecht team worked rather in the shadow of public (and experts) attention, in order to have room for decision making for- and with the residents and direct stakeholders. This approach is much closer to the thoughts of adjusting power and for reaching a just and lasting society.

The questions we explored were: "are the political agenda of equity planning expressed in the planning instruments?" And if so: how does this affect the substance of planning? Does it make cities more liveable, bringing health and prosperity to more citizens?

In the cases we have analysed there is evidence that this could work: conditions of collective decision-making and representative staffing shift the priorities in projects and design criteria.

Secondly, the renewal processes are very problem oriented, however these problems are mostly tight to some target group (i.e. vandalism > youth, safety > elderly).

A third conclusion is that the objectives of equity planning are frequently mentioned in the policy documents (i.e. European development perspective –Lisbon- or local documents), but far from being embedded structurally in planning processes. It needs a 'martial law' such as IBA, ISV or Soziale Stadt enforcing criteria of integration, participation etc., to have a real impact on the planning process. To articulate the political will is the first step to create new, prosper living places, but by itself a paper tiger.

Finally: have we found a role model? No plan or planning team is perfect, yet the potential is there. Inasmuch circumstances can be improved at local level, the spatial environment and the residents certainly benefit from equity planning. Sharing and analyzing the experiences with new planning tools will help practitioners to operate more effectively.

Crime prevention through environmental design in residential developments in Tehran

Nasim Iran manesh, Kouros Etaati

(Nasim Iran manesh, Islamic Azad University- west Tehran branch, niranmanesh@yahoo.com)
(Kouros Ettati, Jarf Sanat Saina co., k_etaati@yahoo.com)

1 ABSTRACT

Security is an essential factor in residential communities, without security any residential community will not form and there will be no more meaning for it. Residential complexes which face with various crimes or there is a fear of being victim by various crimes in them will be damage or won't work well.

Actually creating security without attending police and guards in them especially in large residential complexes is impossible; but we can use some other factors such as participation of residences and suitable urban design to decrease the need of attending of police and guards for creating security and peace.

In my metropolitan, Tehran, there is a high density in residential communities and in result highrise buildings with a large numbers of residential units have been created.

This problem causes to create some districts that their residences don't know each other and the concept of "neighborhood" has no meaning in them.

Besides ,there are many spaces in residential communities which are indefensible and the security of residences will be in danger.

Lack of separation of "stranger" and "familiar" in residential communities and especially in residential complexes causes to increase the crimes and lack of security for people especially for vulnerable people such as children, women and elderly.

In this article I will try that after surveying various residential complexes and categories them, I will present some suitable methods to avoid crimes.

In the other words, residences themselves can be able to create defensible spaces in their residential environment.

Residential land use is a major land use in a city, creating a sustainable and safe for citizens in their residential environments is a very essential factor in creating a livable, healthy and prosperous city.

2 CPTED IN RESIDENTIAL AREAS

Every day we live with crimes and unfortunately it becomes a fact in our life. Crimes can be ranged from a simple vandalism to greater crimes such as rubbery and murdering and even global terrorism.

In relation with this term the rules usually haven't any attention to prevention and restriction but they often have some rules for arresting and punishment. These criteria that can't be applied before the crime occurred.

Giving attention to this proverb "preventing is always better than curing" can lead us to some guidelines that can be impose in the phase of designing by this techniques a potential offender will feel the risk of being "noticeable" and "identified" and then he will be disappointed.

So the essential question is that how we could design an environment that people feel risk to do illegal activities and in versus encourage doing logical activities.

The other question is that how we can introduce the quality of life in a residential area and how we can improve it to create a livable, healthy and prosperous city.

For this we will try to survey this term in three scales: 1- neighborhood 2- residential complex 3- residential unit

2.1 What's the neighborhood

Neighborhood is a geographically localised community within a larger city, town or suburb. Neighbourhoods are often social communities with considerable face-to-face interaction among members.

2.1.1 Neighbourhoods in the Past: Preindustrial Cities

In the words of the urban scholar Lewis Mumford, "Neighbourhoods, in some primitive, inchoate fashion exist wherever human beings congregate, in permanent family dwellings; and many of the functions of the

city tend to be distributed naturally—that is, without any theoretical preoccupation or political direction—into neighbourhoods."

The sociology of modern neighbourhoods

- Neighbourhoods have several advantages as areas for policy analysis as well as an arena for social action:
- Neighbourhoods are common, and perhaps close to universal, since most people in urbanised areas would probably consider themselves to be living in one.
- Neighbourhoods are convenient, and always accessible, since you are already in your neighbourhood when you walk out your door.
- Successful neighbourhood action frequently requires little specialised technical skill, and often little or no money. Action may call for an investment of time, but material costs are often low.
- With neighbourhood action, compared to activity on larger scales, results are more likely to be visible and quickly forthcoming. The streets are cleaner; the crosswalk is painted; the trees are planted; the festival draws a crowd.
- Visible and swift results are indicators of success; and since success is reinforcing, the probability of subsequent neighbourhood action is increased.
- Because neighbourhood action usually involves others, such actions create or strengthen connections and relationships with other neighbours, leading in turn to a variety of potentially positive effects, often hard to predict.
- Over and above these community advantages, neighbourhood activity may simply be enjoyable and fun for those taking part.
- But in addition to these benefits, considerable research indicates that strong and cohesive neighbourhoods and communities are linked –quite possibly causally linked – to decreases in crime, better outcomes for children, and improved physical and mental health. The social support that a strong neighbourhood may provide can serve as a buffer against various forms of adversity.

3 THE RELATION BETWEEN THE DESIGN OF NEIGHBORHOOD AND CRIMES

Various people have some theories about the relation of the design of neighborhood and crimes. Jane Jacob and Oscar Newman are two of the most famous of them . Oscar Newman presents the „defensible space „ theories to create ownership feeling for residences of a neighborhood and Jane Jacob defends the theory of attending the residences specially children in urban spaces for long time and different activities.

Here are short explanation of this:

3.1 The relation between urban design and crimes as Newman theories:

Oscar Newman is an architect and urban designer whose books and theories in urban designing , public houses and pereventing crime are so famous.

Newsman says when there are some public spaces in highrise buildings such as public spaces and open spaces , the residences can't feel any reponsibility for their security and maintenance of them and these spaces will be vulnerable. The surveys show that two factors are the most important factors. The physical factors include the size of family and the number of families sharing common entrances.

Two social factors include the rate of income of the family and the ratio of teenagers to adult. So as changing the social structure of residence is impossible, the only possibility to modification is physical improve, it means changing in project size and the number of apartments that are sharing in a common entries.

The size of project is a measure to concentrate of families, Newman reached to this result that the more concentration, the more insulation of residences from the whole of community. The size of residential complex has a direct relationship with the amount of crimes in it. A large project create a continuous area that even a gang of drug sellers can polluted all of the common areas. The rate of sharing in entries of buildings, elevators and common stairs is an important factor. More people who are sharing in common areas, the more difficulties will be appeared. The main problem is in recognizing residences from offenders

and there are more difficulties for residences to corporate with the rest of residence on the care and control of these areas.

The size of building has some effects on the behavior of residence as follows:

- using shared spaces in residential complex
- social interaction with neighbors
- sense of control over the interior and exterior public area of their development

The results of this surveys shows that the size of buildings has a great effect on the fear of crimes and on the community instability.

Newman defends from creating the sense of ownership for these spaces by dividing and allocating them to people to use and control them like private areas.

3.2 The relation between urban design and crimes as Jane Jacob

One of the offenders of theory of the natural surveillance is Jane Jacob that in her book "the life and the death of American cities" states that to reach a safe and health life in communities, the relation between neighbors and users of public areas is a fundamental factor and so the urban space should create this possibility.

It should be said that Jacob emphasizes on designing urban spaces and social patterns.

Jacob believes that in a neighborhood for caring and surveillance from street we need some "eyes", the eyes of whom that she calls them "natural owner of street". The buildings that are near the street should be faced toward it. These building shouldn't turn back to the street and shouldn't present their blind facades to them.

The walkway should be used continuously; this is the only possibility to increase the number of eyes in the street and to attract the look of whom that are attending in buildings , nobody don't like to look on an empty street and in versus many people like to make them busy by looking on a crowd street in a day.

Jane Jacob by her theory presents some walkways with 10 to 12 meters width for adapting various things such as planting, children activities, passing the people, and general life for adults.

3.3 CPTED and social police :

CPTED and social police can be as a part of comprehensive strategies to prevent crimes.

In the ways of preventing crimes and social police the main emphazise in it is on the solving problem than preventing crimes, such as close cooperation between police and residence in reducing crime and fear of crime. Because these principles emphasizes on systematic analyzing of crimes in a special place, this fact directly support social police with creating strategies for preventing crimes than solve special problems. Police, citizens and government has a great role in preventing crimes by making policy for preventing crimes and urban designing:

Police interfacing and his contact with neighborhood can be included both walking and grouped working to enforce the sence of safety of citizens and solviong the problem of neighborhood that are sharing in crime or fear of it.

Residence can be cooperated with each other to improve the apearance of community and prevent from crimes.

The government can use building codes and inspector forces to increase the safety of environment and district.

3.4 Surveillance on neighborhood :

The first step to prevent crimes begins by removing criminal activities from neighborhood and then with developing neighborhood relationship can prevent from crimes.

Crime prevention through environmental design will cause by removing the opportunities of occurring the crimes ,so we can create "target hardening". These ways includes:

- increasing the ability of looking and lighting

- landscaping with access control
- the possibility of interfacing the neighbors with each other by organized relationships
- creating outdoor activities for young and adult people

4 CPTED IN RESIDENTIAL COMPLEXES

Introduction:

A residential complex means a place that includes some residential units with a special arrangement. We can categorize residential complexes in several types that each of them has some negative and positive points.

The surveys show that two physical factors and two social factors are effective in most of crimes.

Two physical factors include the size of project and the number of families who are sharing in common spaces in a building.

Two social factors are the percentage of low-income families and the ratio of teenagers to adults.

How much the size of project or concentration of family is getting lager the residences will feel more irresponsibility about their environment, this irresponsibility will reach to the other services such as police, refuse collection , education and so on.

The more residences who are sharing in a common place, the more difficulties to distinguish residences from offenders then there are more problems to control these spaces.

4.1 The recommendations for safety design in residential complexes

Generally most of the safety strategies that can be applied in these complexes such as high fences and gates with electronic eye may have negative effect instead of positive effect on residences.

With applying these ways in the complexes we can create a safe environment without using usual devices. For instance, designing street with using gateways, squares, speed signs and other devices which reduce the speed of traffic and by making public spaces visible we will say to offenders to think again before doing a crime.

Implementation of these policies is simple and inexpensive and in compare with doors and gateways, they have a positive effect on residences.

We can categorize safety design recommendation for residential complexes as follows:

Natural access control:

- the access should be limited (without complete segregation of complex with adjacent complexes)
- the design of streets should reduce traffic.
- The pavements, planting and architectural design should take away visitors from private spaces.
- The walkways should lead pedestrian traffic well and don’t be hidden

Natural surveillance:

- The landscaping shouldn’t create blind or hide points
- Open green spaces and recreation spaces should be visible from adjacent houses
- We should use special lighting for streets and for pedestrian to light high traffic walkways.

Enforcing territories :

- The lots , streets and houses should be designed to increase the contacts between neighbors
- The entrances should be emphasized by using different material , variation in facades of street, architectural design , and landscaping
- Residences should be leaded by the signs of streets clearly; the numbers on the signs should have 15 cm height and should be lit very well.
- The ownership of boundaries should be indicated with column and fences and gateways and planting to lead pedestrian.

- All of the parking should be identified well.

5 CPTED IN RESIDENTIAL UNIT:

Introduction:

The residential unit is the last scale for our surveying. In this section a residential unit means a single family unit to multifamily less than ten families.

5.1 The suitability of type of building with the style of life of groups:

Generally high-rise buildings are not suitable for low-income family with children but this conclusion isn't true that high-rise buildings aren't suitable to live.

For example, elderly even low- income ones can live very well in high-rise buildings.

Elderly don't like climbing stairs but they welcome to elevators. Retired people often live far away their children and their old neighbors become a vast family for them. With pressing a button they can reach to hundred families in a high-rise building.

If we design the ground floor of high-rise building for elderly as a recreational and shared place, we can create a safety station in the entrance of building that can be managed by some volunteer from elderly.

If there is a problem they can aware police with pressing a button.

Of course it should be said that applying such things needs some special guideline and notes that follow local codes and social characters of that place.

6 SAFETY GUIDELINES FOR SINGLE FAMILY OR MULTI-FAMILY BUILDINGS

Multi-family buildings have the same problems of single family buildings, although these problems will increase with more residences, in multi- family houses we face with more common spaces: local corridors, elevators and parking.

By giving attention to this note "safety is in numbers", so existing a limit number of neighbors who feel responsibility about each other there isn't any reason that a multi- family building couldn't be a safe place to live.

Safety guidelines for a residential single family unit or multi-family unit are these:

6.1 Natural control access:

- The fence of balcony should never be built by opaque and solid material and its height shouldn't be more than 1 meter
- The entrance of parking lots should be indicated with landscaping or architectural design or have guard
- The dead spaces should be closed with fence or gateway
- Common entrances of the buildings should have some locks that could be locked automatically
- The corridors should be lit well
- Elevators and stair should be placed in center
- The access to building shouldn't be more than two points

6.2 Natural surveillance:

- The exterior doors should be visible from the street or by neighbors
- All of door that open to outdoor spaces should be lit well
- Every side of building should have window
- Parking should be allocated to the adjacent unit and should be marked with the number of the apartment
- A keeper for parking should be indentified

- Parking should be visible from windows and doors
- Recreational spaces should be visible from most of windows and doors
- The bushes shouldn't have more than 1/1 meter height
- The buildings should be located in a manner that the windows and doors of one unit can be seen by other units
- The stairs should be lit well and outdoor sense should be seen , it shouldn't be surrounded by solid walls

6.3 Enforcing territories:

- The boundary of ownership should be identified with landscaping or column and fences
- Bushes and fences should be short to be able to see the street
- Entrances of building should be indicated with architectural elements , lighting or landscaping
- The handhold of the door should be 90 cm lower from the glass of door
- All of buildings and residential units should be indicated clearly with the number of street (the min height should be 12 cm) and should be lit well in night
- The common entrances should have windows and the lock should control by residences
- The post box should be near residence

6.4 THE CASE STUDY: SAHRE-ZIBA BOULEVARD IN TEHRAN CITY

Sahre-ziba Boulevard located in the west of Tehran is a residential district with about 600 residential units that was built about 50 years ago.

The houses of this area are some blocks with four levels which are located around a boulevard whose name is Shahre-ziba Boulevard.

Aerial photogragh of Share-Ziba region

According to the interview that had been done with the residences of this district the majority of residences claimed from its old situation and its disordering. Unsafety and gathering of strangers for crime activities such as drug selling were some other complaint that they pointed.

General view of buildings in Share-Ziba residential complex

Because of a large school that was located in the end of this complex, the entrance of strangers and making a large crowd while closing up the school was the other cases to claim.

The main reason of creating unsafety in this district is the possibility of entering the strangers to this residential complex which causes that familiar people can't be distinguished from strangers as well as tall trees which obstacle view permit offenders to hide in many places of this area.

Undifiened spaces around the buildings

The solution for this problem is surrounding this area and creating limited access for residences or by facilitating the open spaces between blocks and creating the possibilities for presenting of children and elderly in this area create a very effective natural surveillance for that complex.

Adequate lighting and specially lighting the hidden places will be an effective factor to threaten the offender from doing crime as well.

Meanwhile providing a local shopping center along with other facilities such as a coffee shop and so on will increase natural surveillance as well.

In this area private spaces have been arranged in front of houses as some courtyards with transparent fences. We can add some semi-private spaces for this area that people feel responsibility for maintaining plant and grass and other services of these areas and don't release these areas.

Building with its front courtyard

7 CONCLUSION

The ways of preventing crimes through environmental design have a long way to reach environmental safety. Of course these principles can't keep a community safe lonely. These ways can recognize problematic places and reduce their difficulties, such as distinguishing a blind lane, bad lighting in parking and crowd entrances.

Fortunately implementing these ways create a sense of safety and relaxation along with responsibility for neighbors which is the greatest tool to prevent crimes.

At the end it should be repeated that the final aim of all of these strategies is promoting the qiuality of life in city and creating a livable, healthy and prosperous city.

1 ABSTRACT

Cities in all parts of the world face mounting challenges such as population shifts, water shortages, air pollution, inadequate or aging infrastructure, land degradation, sprawl, spread of informal settlements and traffic congestion. Metropolitan cities grow beyond imaginable proportions. Concentration of intense economic processes and high level of consumption in cities increase their resource demands. The main problem with cities today is that they have become centres of mobilisation rather than civilisation. The city of the future, to be sustainable, will have to re-establish the concept of civilisation, with sustainable mobility.

2 INTRODUTION

During the Last Century Urban Population of India increased ten folds from 27 million to some 270 million. Cities today are in the centre-stage of environmental pollution, and degradation and loss of bio-diversity. Concentration of intense economic processes and high level of consumption in cities increase their resource demands. Beyond their boundaries, cities affect traditional rural economics and their culture. The main problem with cities today is that they have become centres of mobilisation rather than civilisation. They are nodes of an increasingly intense economic activity, with the volume of travel having reached unprecedented levels in recent years. The urban economic culture has a deep impact on the human mind, which has become too pre-occupied with the pursuit of personal gain. The city of the future, to be sustainable, will have to re-establish the concept of civilisation, with sustainable mobility.

Delhi, the fast growing Capital City of India has presently a population of about 17 million persons and is estimated to grow in a 23 million population Mega City by the year 2021. After Independence Delhi had 1.43 million populations by 1951 and has increased to 8.42 million by 1991. According to 2001 Census of India it has reached to 17 million just 100 percentage increase. Ever increasing population with end lasting demand can be sustained with adopting an integrated approach towards Urban Transport System. The Ministry of Urban Development, Govt. of India formulated National Urban Transport Policy (NUTP), 2006 with broad objective to ensure safe, affordable, quick, comfortable, reliable and sustainable access for public transport within cities. One of the objectives is to “enabling the establishment of quality focused multi-modal public transport systems that are well integrated, providing seamless travel across modes”.

Sustainable mobility is defined as the primary goal of transport policies together with rising importance of environmental quality in the city. The concept of sustainability within transport policies need to accommodate at least three main objectives: economic growth, social equity and environmental sustainability. Usually it is not easy because all three objectives are multi-dimensional themselves.

3 NEED OF STUDY

Delhi today is emerging as one of the largest and most populated cities of the world. Out of a total area of 1483 sq km about 50% has already been urbanised and the rest is under heavy pressure of urbanisation. In spite of the plans for decentralisation and to restrict the growth of the city by development of National capital Region (NCR), the runway growth of Delhi continues. Putting several strain and demands on mobility Delhi has been evolved for creation of a sustainable transportation model for reducing its carbon foot.

Effective and reliable transport systems are crucial for the functioning of the post industrial economies, yet such systems generate significant negative externalities like air pollution, noise vibrations, energy consumption, and emission of greenhouse gases and loss of open space. Worldwide examples show that there is a small reduction of energy consumption and CO2 emissions in motorized modes of transport. It is proved that reducing CO2 emissions from the transport sector is much easier than cutting those from the building sector. However it is promising, that any new approach that involves a change in vehicle technology or a shift to different mobility technologies and techniques can be implemented in a relatively short time. Transport, therefore, is a very important element in our race toward sustainable life on earth.

4 STRATEGY OF SUSTAINABLE MOBILITY

In the above stated background the following three fold approach and strategy needs to be adopted:

- Multi modal transport system with Pedestrian Policy (walkable city)
- Motorized Vehicles in Mass Rapid Transit System
- Policy for local environment and safety.
- Institutional /Regulatory Interventions.

5 WAY TO CARBON NEUTRALITY THROUGH SUSTAINABLE MOBILITY

5.1 Modality and Landuse Efficiency

Urban Form: Delhi city is an assemblage of buildings and streets, system of communication and utilities, places of work, transportation, leisure and meeting places. Delhi had a traditional Urban Design which is reflected in the glory of 17th century the Walled City of Shahajahanabad and New Delhi in 1916, the Central Vista was conceived as a landscaped stretch to form continuity between the ridge and the river Yamuna.The boulevard of Chandni Chowk was its commercial centre piece Red Fort and Fateh Puri Mosque as its two ends. The stretch with the Rashtrapati Bhawan and the India Gate at two ends has tremendous visual quality. The Jama Masjid a dominating feature located on hill top was visually linked with Parliament House, Connaught Place in the same axis. To make city with footstep of carbon neutrality several measures have been taken integrity of land use in urban form.

Delhi, like most Indian cities, has a mixed pattern of land use. This is partly because large numbers of people need to walk between their places of residence and their places of work. No clear-cut concentric zones of different activities exist. Central core areas comprise not only commercial development but also high-concentration housing, and working-class developments are found in the core and vicinity of the city. Manufacturing activity is spread geographically not only in the peripheral zone but also in the intermediate and inner zones.

In Metropolitan Centre and Extension: Connaught Place: Landscape Schemes are prepared to integ-rate MRTS stations, safe pedestrian walkways, parking areas, recreational and cultural areas, etc.with planting of trees and street furniture. The intermediate public transport such as monorail, battery oper-ated / high capacity buses, sky buses are introduced to increase the mobility within the City Centre. Use of alternative renewable sources of energy is encouraged for new buildings (especially those of commercial or institutional nature), traffic signals, public signages, etc.

In Walled City And Extensions: Conservation approach to retain the overall traditional character of the Walled City. Pedestrian made completely free of vehicular traffic so as to restore the human scale and convenient living, controls considering built to edge typology to enhance environmental state.

In District Centres: The district park adjoining to the district centre proposed in the master plan / zonal plan should be properly integrated with the district centre. The area provided for landscape as part of the district centre should weave through the entire district centre to create a pleasant environment with access to main circulation system. Either ring road or outer ring road.

5.2 Management of Natural Resources

Natural Resources: The major natural features and eco-systems of Delhi are the river Yamuna, together with a network of streams/drains that empty into the river, and the Aravalli Range. Both of these are in a state of considerable degradation, and it is of vital importance to conserve and rejuvenate these ecosystems. This has regional carrying capacity, therefore, surrounding states also have to contribute towards their conservation and rejuvenation. Measures for Rejuvenation of River Yamuna is maintain minimum flow in river Yamuna to be ensured by Riparian states by releasing adequate water. The annual rainwater harvesting potential has been carry forward to substantiate the total flow. In this respect all the new bridges/flyovers must have the provision for rain water harvesting.

Air: Various initiatives and measures taken over the past few years, like introduction of CNG and EURO II norms etc., the air quality in the city, in terms of pollution levels, has continued to be a matter of concern, and has been responsible for a number of respiratory diseases, heart ailments, eye irritation, asthma, etc. The

three main sources of air pollution in Delhi are vehicular emission (around 70 percent) industrial emissions (around 20 percent) with a major element of this coming from the three thermal power plants, and from other sources such as diesel generator sets and domestic cooking, burning of biomass, etc.

The major area of planning and intervention would relate to transportation planning. With the phenomenal growth in the number of vehicles, almost 8-10 times in the last two decades in absolute terms, the most significant aspect in the context of congestion and pollution, relates to the growth in personalised transport as compared to the availability of public transport. It has been estimated that buses, which constitute barely 1.2 percent of the total number of vehicles, cater to around 60 percent of the total transport load, while personal vehicles –cars and scooters, though almost 93 percent of the total number of vehicles, cater to around only 30 percent of the travel demand. Such a huge share of private vehicles in Delhi, while serving a relatively limited purpose in terms of the transportation modal split, obviously creates tremendous pressure on road space, parking, and pollution directly and through congestion. Public transportation planning must, therefore, drive the future policy. So far public transport is largely seen as the transport mode for the not so well off and poorer sections of the community, who cannot afford to own/use personal transport. An important element of policy would now also have to aim to make public transport a mode for personal vehicle owners and users through a mix of incentives and disincentives. Apart from aspects like frequency, inter-modal integration, a possible single ticketing system, use of parking policy as a means to influence vehicle use, etc., the quality of public transport, particularly buses, would need to be significantly upgraded, inter-alia, keeping the element of clean transport in view. Another issue which has been raised in the context of vehicular congestion and pollution relates to the policy of mixed land use.

The Metro Rail system has a big footstep for reducing carbon footprint. The Metro Rail system has provided a big relief to the city and placed it on higher demand for providing relief to the 100% metro with adequate feeder system. Use of CNG on public transport has experienced a journey of reducing Carbon emission. It is further paving way for utilization in private vehicles. Bus Rapid Transit is meant to be a high quality public transport system, oriented to the user that offers fast, comfortable and low cost urban carbon mobility. The overall green cover in this zone should be enhanced and protected

MRTS Corridor: In prior master plans, city structure was thought in terms of hierarchies with CBD, District Center and Community Centres in descending order of importance. But with due course of development and introduction of MRTS, need is felt to connect these scattered districts with more imaginable components. These components with enhanced built up areas and activities form a network by which the experience of various district and commercial centres becomes a part of continued experience.

As per the Government of India Notification, it is mandatory for all construction agencies to use Fly Ash bricks or tiles or clay fly ash bricks along with pond ash in the construction of roads/flyovers embankments and reclamation of low-lying areas. To control the ambient air quality of Delhi, it may be made mandatory that all commercial vehicles (like trucks and tempos) are converted into CNG.

5.3 Conservation and Development of Resources

Energy Efficiency:

The concept of energy efficiency should begin with the idea of Zero-fossil Energy Development (ZED) which envisages to reduce the demand for power to the point where it becomes economically viable to use energy from renewable resources. This involves a holistic approach combining the issues and actions at various levels of planning, design, construction and maintenance leading to a sustainable and energy efficient regime. The city geometry, restructuring and zoning with self-contained neighbourhoods could minimise the need to travel and substantial saving of recurring energy/ fuel consumption. Integrated mass transport system, traffic and transit operation and management, better tele-communications, promoting bicycles and NMV transport, is another major area of energy efficient habitat. The introduction of energy audit and design of energy efficient form, construction and materials and reducing energy demand by passive micro-climatic design approach, intelligent energy controls, heat recovery, landscape, opening design, furnishings, etc., are the critical considerations. The key to future is a cybernetic form of sustainable energy, which integrates symbiosis, recycling and energy chains.

Non-conventional energy sources like recovering energy from solar energy, etc. should be used for street lighting, lighting at public spaces, open areas, traffic signals, hoardings, etc.

To supplement part of the estimated growing power requirement, non-conventional sources/solar energy and other actions proposed are as follows:

- Compulsory Solar Panels for public advertising, lighting in open areas, public utilities, streets, etc.
- Adoption of Load Management Technique.
- Tariff restructuring and improved metering arrangement to minimize power thefts/losses.
- Private Sector Participation in different stages for Inter Modality system and adapt of new techniques.
- Incentivising energy savings and use of energy efficient gadgets.
- Public awareness, capacity building and training.

As per Asian Development Bank's report (1997) potential in saving due to better overall efficiency in Transport Sector by adopting following measures:

- Incandescent bulbs, neon tubes and fluorescent lamps are giving way to light-emitting microchips that work longer, use less power and allow the use of light in new ways. The chips, known as light emitting diodes, or LEDs have huge performance advantages in many mundane tasks (such as traffic lights). These consume 80 per cent less electricity than the bulbs and have longer life. Moreover, they have the safety advantage of gradually fading instead of burning out. This eventually results in huge savings in terms of energy and maintenance costs.

6 CONCLUSION

Management of logistics in Transport Sector provides an opportunity to use renewable solar energy for saving energy and green Clean Gas for saving gaseous emissions in climate, Mass Transit System for door to destination with inter modality service towards Carbon Neutral City.

Der Beitrag regionaler Verkehrspolitik zur Realisierung der Vision lebenswerter, gesunder und prosperierender Städte für alle: Beispielfall Burgenland

Elmar Fürst, Verena Matz

(Dr. Elmar Fürst, Institut für Transportwirtschaft und Logistik, WU Wien, Nordbergstr. 15, 1090 Wien, Österreich, elmar.fuerst@wu.ac.at)
(Mag. Verena Matz, c/o Institut für Transportwirtschaft und Logistik, WU Wien, Nordbergstr. 15, 1090 Wien, Verena_Matz@gmx.at)

1 EINLEITUNG

Im Rahmen einer Studie der Landesstelle Burgenland der Österreichischen Verkehrswissenschaftlichen Gesellschaft (ÖVG) und des Instituts für Transportwirtschaft und Logistik der WU Wien wurde die Verkehrspolitik des Burgenlandes einer genauen Betrachtung und Analyse unterzogen. Zahlreiche Interviews mit Entscheidungsträgern auf Landes-, Bezirks- und vor allem auf kommunaler Ebene sowie mit Vertretern von burgenländischen Verkehrsunternehmen zielten darauf ab, die aktuelle Situation und Entwicklungen in der burgenländischen Verkehrspolitik zu analysieren und dadurch die Rolle der regionalen Verkehrspolitik bei der Gestaltung gesunder und prosperierender Lebensräume darzustellen. Es konnten sehr interessante Ergebnisse erarbeitet werden. Unter anderem werden unterschiedliche Maßnahmen aufgezeigt, die Entscheidungsträger aktuell ergreifen, um Städte und Dörfer im Burgenland für die Bevölkerung lebenswert und attraktiv zu gestalten.

2 PROBLEMSTELLUNG

Attraktive Lebensräume haben für den Menschen viele unterschiedliche Eigenschaften: gute Erreichbarkeit (sowohl durch Individual- als auch den öffentlichen Verkehr), gesunde Umwelt, (Nah-)Versorgung, bedarfsgerechte Infrastruktur und Nähe zu Ausbildungsstätten und Arbeitsplätzen sind nur Beispiele dafür, was Menschen in Betracht ziehen, wenn es darum geht, ihren idealen Lebensraum zu beschreiben. Diese Faktoren sind auch von großer Bedeutung, um das Grundbedürfnis des Menschen nach Mobilität und Freiheit befriedigen zu können. Um einen optimalen Lebensraum für die Bevölkerung gewährleisten zu können, stehen Entscheidungsträger auf regionaler Ebene vor vielfältigen und teilweise konfliktären Aufgaben. Dabei gilt es, neben den Wünschen und Forderungen der Bevölkerung auch die Anforderungen von Wirtschaft, Umwelt und Politik in Lösungen einzubeziehen und unterschiedliche Interessenlagen zu berücksichtigen. Steht für die Wirtschaft eine maximale Erreichbarkeit und optimale Verkehrsanbindung im Zentrum des Interesses, so beeinflusst dies die Umwelt mitunter aufgrund des steigenden Verkehrsaufkommens negativ. Die Anforderungen einer intakten Umwelt stehen also manchmal im Gegensatz zu jenen von Wirtschaft und Industrie.

Neben den unterschiedlichen Ansprüchen der verschiedenen Akteure („Steakholder-Ansatz“) beeinflussen auch regionale Besonderheiten, demographische Trends (Stichwort „Landflucht“ oder „alternde Bevölkerung“) bzw. auch die sozio-ökonomische Lage das Entscheidungsspektrum von politischen Akteuren. In größeren Ballungsräumen sind dabei naturgemäß andere Maßnahmen notwendig als in kleinen Gemeinden. Entscheidungen müssen also auf der jeweiligen Ebene spezifisch getroffen werden.

Das Burgenland stellt seine Entscheidungsträger dabei vor große Herausforderungen, wie der folgende Überblick zeigen soll:

Die Gesamtfläche von 3.965,5 km² ist auf sieben politische Bezirke aufgeteilt[1]. Die Bezirke Neusiedl am See, Eisenstadt-Umgebung und Mattersburg bilden dabei das Nordburgenland, der Bezirk Oberpullendorf das Mittelburgenland, die Bezirke Oberwart, Güssing und Jennersdorf das Südburgenland. Die drei burgenländischen Großregionen weisen dabei äußerst unterschiedliche Siedlungsdichten auf: Das Nordburgenland hat mit 82,29 Einwohnern/km² die höchste Siedlungsdichte, im Südburgenland beträgt die Dichte durchschnittlich 66,42 Einwohner/km². Das Mittelburgenland ist mit 53,46 Einwohnern/km² am

[1] Vgl. Amt der Burgenländischen Landesregierung (2009), http://www.burgenland.at/media/file/226_flaeche_burgenland.pdf

dünnsten besiedelt[2]. Dabei gilt die Streusiedlungsstruktur im Landessüden als besondere Herausforderung für verkehrspolitische Entscheidungen[3].

Insgesamt beherbergt das Burgenland 171 Siedlungsgebiete, darunter zwei Freistädte, elf Stadtgemeinden, 65 Marktgemeinden und 93 Gemeinden[4]. Die Karte auf der folgenden Seite zeigt das Burgenland mit seinen Gemeinden, Bezirken und Bezirksvororten im Kontext der Nachbarstaaten und -bundesländer.

3 GESTALTUNGSMÖGLICHKEITEN DER REGIONALEN VERKEHRSPOLITIK

Inwieweit die regionale Verkehrspolitik konkret Einfluss auf die Gestaltung attraktiver Lebensräumen nehmen kann, wird nun im Vorfeld der Besprechung diesbezüglicher Ergebnisse der Studie kurz erläutert.

- Gerade in ländlichen Gebieten sollte verstärkt darauf geachtet werden, dass diese verkehrsmäßig gut erschlossen sind und gute Anbindungen in die nächstgelegenen Ballungszentren – und somit zu Versorgung, Ausbildung oder Arbeitsplatz – geschaffen, erhalten und ggf. weiter ausgebaut werden. Dies sollte sowohl für den Individual- als auch für den öffentlichen Verkehr beachtet werden, um Mobilität für alle Bevölkerungsgruppen gewährleisten zu können. Individualverkehr und öffentlicher Verkehr können sich dabei ergänzen, um auch umweltpolitischen Zielen gerecht zu werden (Stichwort „Park-and-Ride“). Auf diese Weise erfährt die betroffene Region eine Aufwertung, was die Attraktivität steigert und das Gebiet lebenswerter macht bzw. Entleerungen in Richtung der Ballungsräume hintanhält.
- Betreffend den öffentlichen Verkehr kann Rentabilität nicht im Mittelpunkt des Interesses stehen. Öffentlicher Verkehr kann unter dem gegebenen Regime der Objektfinanzierung – gerade in dünn besiedelten Gebieten mit wenigen Nutzern – oftmals nicht durch die eingehobenen Tarife finanziert werden, die Finanzierung obliegt folglich der öffentlichen Hand im Rahmen gemeinwirtschaftlicher Leistungsverträge. Aber gerade ÖV-Verbindungen sind vielfach notwendig, um die Lebendigkeit und Attraktivität einer Region zu erhalten.
- Von großer Bedeutung ist auch die Einbeziehung der Bevölkerung in die Gestaltung von Lebensräumen. Neben den Entscheidungsträgern und Fachleuten sind es auch oft Ideen der Bevölkerung, die innovative und kreative Lösungen im Verkehrsbereich ermöglichen. Dabei kann die Politik etwa durch Förderung von Ideen oder auch Bereitstellung von Plattformen (z.B. Bürgerforen, Ideenwettbewerbe, etc.) zu einem verbesserten Verhältnis zwischen Politik und Bevölkerung beitragen und im Zuge dessen mit der Bevölkerung zusammenarbeiten und Verbesserungen erreichen.
- Ein großer Anteil der burgenländischen Bevölkerung pendelt über die Bundeslandgrenzen hinweg zum Arbeitsplatz. Die tägliche Überwindung von langen Strecken wirkt sich naturgemäß auf die Lebensqualität der betroffenen Menschen aus, da durch die langen Anfahrtszeiten wertvolle Freizeit verloren geht. Diese Problematik kann entschärft werden, indem Ansiedlungen von Betrieben angestrebt werden. Diese Vorhaben sollten bereits in der Flächenwidmung berücksichtigt werden, um eine optimale Ausgangsposition für Unternehmensansiedlungen zu schaffen. Der Faktor Zeit wird für die Menschen, die eine gesunde Work-Life-Balance erreichen möchten, immer wichtiger.
- Eine intakte Umwelt bildet die Basis einer lebenswerten Region. Daher sollte bei Verkehrsprojekten stets der Aspekt des Umweltschutzes – über den gesetzlichen Rahmen hinaus – im Auge behalten werden. Starke Eingriffe in die Natur (z.B. durch Trassenführungen), die Führung von sehr stark frequentierten Strecken durch Siedlungsgebiete (Lärm- und Abgasproblematik) oder auch die Verwendung von veralteten Technologien (Fahrzeuge mit hohem CO2-Ausstoß) führen zu Effekten, die sich negativ auf den Menschen und dessen Zufriedenheit auswirken. Der Umweltbezug sollte sich nicht auf Aktivitäten von Entscheidungsträgern beschränken, vielmehr sollte die Bevölkerung idealerweise frühzeitig in Planungsprozesse involviert werden, was Planungs- und Zeitkosten aufgrund von Verzögerungen infolge von Widerständen („Bürgerinitiativen“) senkt. Politische Entscheidungsträger können dabei durch Bewusstseinsbildung in der Bevölkerung wichtige Schritte in Richtung lebenswertes Land, Region und Gemeinde erzielen.

4 EMPIRISCHER BEFUND

4.1 Methode

Um im Rahmen der Befragung Repräsentativität auf allen Ebenen zu gewährleisten, wurde ein detaillierter Stichprobenplan erarbeitet:

Die Landesebene sollte möglichst umfassend berücksichtigt werden, dabei waren vier Referate bzw. Institutionen der burgenländischen Landesregierung für den Verkehrsbereich von Relevanz. Es handelt sich um das Hauptreferat für Verkehrsrecht, das Hauptreferat Straßenausbau und das Referat Gesamtverkehrskoordination. Weiters spielt auch die Mobilitätszentrale Burgenland, welche Teil der

Regionalmanagement Burgenland GmbH ist, eine wichtige Rolle im Verkehrsbereich und wurde ebenfalls miteinbezogen. Alle Instanzen konnten für die Mitarbeit am vorliegenden Projekt gewonnen werden.

Auf Bezirksebene vier von sieben Bezirken erreicht, wodurch auch auf dieser Verwaltungsebene hinreichende Repräsentativität sichergestellt werden konnte.

Auf Gemeindeebene wurde eine Schichtung auf Basis der Einwohnerzahl[5] vorgenommen. Größere Gemeinden mit mehr als 3.000 Einwohnern bilden die eine Gruppe, die bevölkerungsärmeren Gemeinden die andere. Das Burgenland zählt aktuell 15 Gemeinden, mit einem Bevölkerungsstand von über 3.000. Aufgrund der regionalen Unterschiede sollte möglichst eine Vollabdeckung erzielt werden, letztendlich wurden elf Gemeindevertreter erreicht, die verbleibenden vier standen für ein Interview nicht zur Verfügung. In der großen Gesamtheit der kleinen Gemeinden wurden pro politischen Bezirk drei zufällig, ausgewählt im Ablehnungsfall wurde innerhalb des Bezirkes eine Ersatzgemeinde ermittelt. Insgesamt konnten die Vertreter von 18 Gemeinden mit weniger als 3.000 Einwohnern für ein Interview gewonnen werden, elf weitere kontaktierte Gemeinderepräsentanten standen für eine Erhebung in ihrer Gemeinde nicht zur Verfügung.

Die Gruppe der Verkehrsunternehmen bzw. -verbünde komplettiert die Stichprobe gleichsam als Kontrollgruppe oder Korrektiv. Es wurden sechs Unternehmen kontaktiert, davon standen vier Vertreter für die Befragung zur Verfügung. Diese Erhebungen wurden zur Reflexion der Ergebnisse der verschiedenen politischen Ebenen durchgeführt, können jedoch nicht als repräsentativ betrachtet werden. Dennoch konnte erreicht werden, dass die Tätigkeitsgebiete der befragten Verkehrsunternehmen bzw. -verbünde alle Landesteile des Burgenlandes abdecken.

Im Grundsatz erfolgte die Durchführung der Interviews in den Räumlichkeiten des Gesprächspartners, sämtliche Interviews wurden von der Mitverfasserin des vorliegenden Beitrags persönlich durchgeführt. In Ausnahmefällen wurde – um sich den Meinungen dieser Personen nicht zu verschließen – einer telefonischen bzw. schriftlichen Befragung zugestimmt. Dies ist erhebungstechnisch nicht optimal, ansonsten hätte man auf die Meinungen dieser Befragten gänzlich verzichten müssen. Insgesamt wurden im Zeitraum Februar bis Juli 2009 41 Interviews durchgeführt, von diesen erfolgten 32 persönlich, drei telefonisch und in sechs Fällen erfolgte die Befragung in schriftlicher Form.

Zum Zwecke der Durchführung der Interviews wurden Interviewleitfäden für sämtliche Träger der burgenländischen Verkehrspolitik und auch Verkehrsunternehmen bzw. -verbünde entwickelt. Behandelt wurden dabei folgende Themengebiete:

- Zusammenarbeit der unterschiedlichen politischen Ebenen
- Entwicklung der Mobilitätsansprüche der Bevölkerung
- Die unterschiedlichen Verkehrsträger im Detail
- Verkehrspolitische Zielsetzungen
- Güterverkehr
- Luftverkehr
- Aktuelle Verkehrsprojekte
- Finanzierung von Verkehrsprojekten
- Verkehrssicherheit
- Verkehr und Umwelt
- Das Burgenland im Zentrum der Europäischen Union
- EU-Förderungen im Burgenland
- Burgenländische Verkehrspolitik in der Zukunft

[5] Bevölkerungsstand vom 31.10.2008, analog zu den Ausführungen in der Problemstellung

Alle Interviewleitfäden zeichnet eine gleich bleibende Struktur aus, kleine Abweichungen waren allerdings notwendig, um den unterschiedlichen Tätigkeitsfeldern auf den verschiedenen Ebenen der Politik und der Unternehmen gerecht zu werden.

4.2 Ergebnisse

Die folgende Darstellung der Ergebnisse fokussiert auf ausgewählte Themen, die im Lichte des gegenständlichen Themas relevant sind, also auf den Beitrag regionaler Verkehrspolitik zur Realisierung der Vision lebenswerter, gesunder und prosperierender Städte für alle abstellen. Dabei wird einer konzisen, inhaltlich gesamthaften Darstellung gegenüber einer nach Befragten stark differenzierenden aus Platzgründen hier der Vorzug eingeräumt.

4.2.1 Mobilität

Das Mobilitätsbedürfnis der burgenländischen Bevölkerung folgt weiterhin einem steigenden Trend. Die in den 1970er und 80er Jahren im Burgenland angesiedelten Betriebe wanderten im Zuge des Globalisierungstrends wieder ab und verlegten ihre Produktionsstandorte in Länder mit niedrigeren Lohnkosten. Die Menschen wurden somit gezwungen, für ihren Arbeitsplatz weitere Distanzen zu überwinden und das Burgenland avancierte zum Land der Pendler. In kleinen Gemeinden stellt die schwindende Nahversorgung (Geschäfte, Bildungseinrichtungen, ärztliche Versorgung etc.) eine weitere Begründung dar, warum die Bevölkerung immer mobiler wird. Wurde die Versorgung vor diesen Entwicklungen zumeist ortsintern und zu Fuß oder mit dem Fahrrad erledigt, so ist heute ein Pkw kaum mehr wegzudenken, um in dünner besiedelten Gebieten versorgt zu sein. Gemeinden versuchen dieses Problem durch ortsinterne Bus- und auch Taxikonzepte zu lösen. Dabei wurde beobachtet, dass größere Gemeinden dahingehend stärker engagiert sind als kleinere. Mit dem Thema bedarfsgerechte Gewährleistung von Mobilität beschäftigen auch viele zukünftige Projekte in den burgenländischen Gemeinden, um der Bevölkerung attraktive Alternativen zum Pkw zu bieten.

4.2.2 Die Situation in den einzelnen Regionen

Wie erläutert, sind die einzelnen Regionen des Burgenlandes sehr heterogen. Dies trifft nicht nur auf die Siedlungsdichte zu, sondern wird auch bei der Betrachtung des Modal-split im Personenverkehr deutlich. Im nördlichsten Bezirk des Landes (Neusiedl am See) schlägt der massive Ausbau des öffentlichen Verkehrs auf der Schiene, die ständige Erweiterung der Angebote der Verkehrsverbünde und auch die Parkplatzproblematik bei Arbeitsstätten in Wien sehr stark auf den Modal Split durch: Nach Auskunft der Gesamtverkehrskoordination werden 60% des im Bezirk entstehenden Verkehrs mittels motorisiertem Individualverkehr bewältigt, 12% entfallen auf die Bahn, 6% auf Busverbindungen, 3% auf das Fahrrad und der verbleibende Rest wird zu Fuß bewältigt. Der Anteil von Bahn und Bus ist nicht nur im landesinternen Vergleich sehr hoch, sondern auch österreichweit ist die Beteiligung der öffentlichen Verkehrsmittel am Modal-split im Bezirk Neusiedl am See sehr beachtlich. Der gute Ausbau der Schieneninfrastruktur und auch die zahlreichen Verbindungen (vor allem für Pendler nach Wien) machen dies möglich.

Der gut ausgebaute öffentliche Verkehr trägt zur Lebensqualität in der Region bei, auch die Ende 2007 erfolgte Verkehrsfreigabe der A6 (Nordostautobahn) hat einen großen Anteil daran. Belastete die nördliche Region des Bezirks früher starker Durchzugsverkehr, konnte dieser auf das hochrangige Straßennetz verlagert werden, was zu einer Aufwertung der Region geführt hat.

Die an der A4 (Ostautobahn) gelegenen Gemeinden konnten von dieser positiven Entwicklung allerdings nicht profitieren. Die Autobahn stößt durch das hohe (Güter-)Verkehrsaufkommen an ihre Kapazitätsgrenze, was die Bevölkerung, die den Verkehrsweg täglich zum Pendeln nutzt, stark einschränkt. Hier werden vermehrt Stimmen für eine dritte Spur oder ein Lkw-Überholverbot laut, auf dahingehende Lösungen muss die Region allerdings noch warten. Neben dem Engpass auf der Straße stößt die Park-and-Ride Anlage am Bahnhof in Parndorf Ort seit längerer Zeit ebenfalls an ihre Kapazitätsgrenze. Die verantwortlichen Entscheidungsträger haben die Dringlichkeit des Problems erkannt, ein Ausbau des für die Bevölkerung der umliegenden Gemeinden äußerst wichtigen Verkehrsknotenpunkts befindet sich bereits in Planung.

Auch die Region entlang der B50 ist mit hohem Verkehrsaufkommen konfrontiert. Eine Umfahrung der Ortsgebiete auf der Strecke Neusiedl am See – Eisenstadt wird dabei stark diskutiert, Einigkeit ist allerdings nicht zu beobachten. Stellt eine solche Umfahrung für die einen Gemeinden einen Schritt zur Steigerung der

Lebensqualität dar, empfinden die anderen Gemeinden genau das Gegenteil. Aufgrund der Uneinigkeit konnte hier bisher keine Gesamtlösung gefunden werden. Immerhin ist eine Teillösung bereits in der konkreten Planungsphase, die Gemeinde Schützen am Gebirge im Bezirk Eisenstadt-Umgebung kann voraussichtlich ab 2013 umfahren werden.

Im Bezirk Oberpullendorf ist die Situation rund um die Versorgung mit öffentlichen Verkehrsmitteln gespalten. Das Schienennetz ist vom Nordwesten her bis zur Gemeinde Deutschkreutz elektrifiziert und auch gut verkehrlich bedient, allerdings muss die Bevölkerung der weiter südlich gelegenen Gemeinden auf die Dienste der Bahn weitgehend verzichten. Busverbindungen sind hier für regionale und auch überregionale Fahrten vorhanden. Zwar gibt es qualitative Verbindungen nur Richtung Norden (Eisenstadt, Wiener Neustadt, Wien), in Richtung Süden besteht laut Auskunft der betroffenen Gemeindevertreter Verbesserungspotenzial. Die Auslastung der Straßen in der Region wurde weitgehend als angemessen bewertet, lediglich der Vertreter des Bezirksvororts war mit der Verkehrssituation in seiner Stadtgemeinde nicht völlig zufrieden. Dieser Belastung wird allerdings mit der Verlängerung der S31 bis zum Jahr 2011 Rechnung getragen, die Burgenland-Schnellstraße endet künftig nicht mehr vor der Stadt.

Auch im Bezirk Oberwart haben fünf der sechs Vertreter der befragten Siedlungsgebiete mit starkem Durchzugsverkehr zu kämpfen. Speziell die dort angesiedelten Industrie- und Gewerbebetriebe (z.B. Steinbrüche) sorgen für ein starkes Güterverkehrsaufkommen. Teilweise sind Ortsumfahrungen bereits vorhanden und in Kopplung an diese werden Fahrverbote für das Ortsgebiet von den Gemeindevertretern angedacht, teilweise besteht noch der Wunsch nach Ausweichrouten für den starken Güterverkehr. Die von der steirischen Grenze über Pinkafeld nach Oberwart führende Bahnstrecke kann zum Leidwesen der Bevölkerung nur einen Teil des Güterverkehrsaufkommens auf sich konzentrieren. In kleineren Siedlungsgebieten der Region konnte allerdings beobachtet werden, dass Lösungen für das vorliegende Verkehrsproblem vorhanden sind. Eingeschränkte Befahrungszeiten der Durchzugsstraßen oder auch die Einhebung einer tonnenabhängigen Maut, die zweckgebunden für die betroffenen Straßen verwendet wird, sind Beispiele dafür.

Im südlichsten Bezirk des Landes beträgt der Anteil des motorisierten Individualverkehrs am Modal Split laut Auskunft der Gesamtverkehrskoordination bereits 80%. Lediglich 4% entfallen auf Busverbindungen, die Bahn bewältigt 2% des anfallenden Verkehrsaufkommens. Dabei muss allerdings die Streusiedlungsstruktur im Landessüden beachtet werden, diese Situation stellt verkehrspolitische Entscheidungsträger vor schwierige Aufgaben. Die Bereitstellung von bedarfsgerechten öffentlichen Verkehrsmitteln gestaltet sich hier naturgemäß schwieriger als im Norden. Dennoch wird durch Busverbindungen versucht, vor allem die Pendler des Südburgenlandes so rasch wie möglich zu ihrem Arbeitsplatz zu bringen. Auch hier sind Verbindungen Richtung Norden und Westen den Befragungen zufolge an die Bedürfnisse der Bevölkerung angepasst, Verbesserungspotenzial ist Richtung Süden vorhanden.

Zur Verbesserung der Lebensqualität im Bezirk Jennersdorf wird ab 2014 die S7 (Fürstenfelder Schnellstraße) beitragen. Interviewte Vertreter der umliegenden Gemeinden haben sehr hohe Erwartungen an diesen bevorstehenden Bau, die Lage auf der Strecke zwischen Graz und Budapest und dem dadurch hohen (Güter-)Verkehrsaufkommen sorgt in der Region für Unmut in der Bevölkerung.

4.2.3 Öffentlicher Verkehr

Mit der bereits erwähnten Problematik der Bereitstellung von bedarfsgerechten öffentlichen Verkehren beschäftigen sich die Gesamtverkehrskoordination und die Mobilitätszentrale Burgenland. Die aktuell verfolgte Bahn-Offensive beinhaltet Elektrifizierungen und Sanierungen von bestehenden Strecken im Nord- und Mittelburgenland, die Bevölkerung des Landessüdens kann davon allerdings nicht profitieren. Dort gilt die Erschließung der Fläche mit öffentlichen Verkehrsmitteln als besonders problematisch, denn Kostendeckung kann bei bestehenden Verbindungen oftmals nicht gewährleistet werden. Bedarfskonzepte speziell für die Regionen Mittel- und Südburgenland im öffentlichen Verkehr sind angestrebt und sollten gemeinsam mit den Gemeinden der betroffenen Regionen erarbeitet werden, so ein Vertreter der Mobilitätszentrale. Zielgruppengerechte Lösungen für die eingeschränkt mobilen Bevölkerungsgruppen (Senioren, Jugendliche) sind dabei dringend notwendig, um das Südburgenland für die Bevölkerung attraktiver zu gestalten.

4.2.4 Umwelt und Verkehr

Ein weiteres Augenmerk der Mobilitätszentrale Burgenland liegt auf der Erarbeitung von Konzepten für die Überwindung von kürzeren Distanzen alternativ zum Pkw. Diente das Fahrrad bisher hauptsächlich für Freizeitaktivitäten, so soll dieses auch zum Transportmittel im Alltagsverkehr avancieren. Verbesserungen im Radwegenetz des Landes (Ausbau der Wege und Abstellanlagen) sollen eine Entwicklung dahingehend forcieren. Das Fahrrad gilt dabei als besonders förderungswürdiges Verkehrsmittel, da nicht nur die Kostenersparnis, sondern auch die Gesundheit des Menschen aufgrund der Bewegung und die Schonung der Umwelt überzeugende Argumente darstellen.

Im Bereich der öffentlichen Verkehrsmittel achtet das Land Burgenland beim Abschluss von Verkehrsdienstverträgen darauf, dass Busse mit modernen Dieselmotoren oder auch alternativen Energien (z.B. Erdgas) eingesetzt werden, um die Umweltbelastung so gering wie möglich zu halten. Beim Neubau von Straßen wird der Umweltaspekt miteinbezogen, der Eingriff in die Natur wird für Flora und Fauna möglichst verträglich gestaltet.

Auf kommunaler Ebene ist zu beobachten, dass der Umweltschutz im Verkehr noch nicht jener Stellenwert beigemessen wird, den er auf Landesebene bereits hat. Vertreter größerer Gemeinden beschäftigt der Umweltgedanken im Verkehr stärker als jene der kleineren. Den Status „Klimaschutzgemeinde“ bzw. „Klima-Aktiv Projektpartner“ tragen Gemeinden des Burgenlandes der Erhebung zufolge nur vereinzelt.

4.2.5 Verkehrssicherheit

Bei der Frage nach der Verkehrssicherheit in Burgenlands Gemeinden gaben 28% der befragten Gemeinderepräsentanten an, kritische Bereiche im Ortsgebiet zu haben. In dieser Gruppe sind kleinere Gemeinden allerdings stärker vertreten als größere Siedlungsgebiete. Kritische Kreuzungen, stark frequentierte Straßen im Allgemeinen und ein verstärktes Lkw.-Aufkommen im Speziellen wurden dabei als Gefahrenpotenziale genannt. Um diese Probleme zu lösen, wurde eine Vielzahl an Maßnahmen angeführt, die die Sicherheit für die Bevölkerung in den Gemeinden aktuell bereits gewährleisten bzw. steigern soll. Maßnahmen zur Unfallvermeidung werden in jeder einzelnen der untersuchten Gemeinden getroffen, auch wenn nach Angaben der Vertreter keine kritischen Bereiche vorhanden sind. Der Schutz der Bürger ist auch stark in den definierten verkehrspolitischen Zielsetzungen der Gemeinden verankert.

Auf Landesebene spiegelt nach Auskunft von Landesvertretern das aktuelle Verkehrssicherheitsprogramm „Fair & Sicher“ den Stellenwert dieses Themas wider. Im Rahmen des Programms werden jährlich Schwerpunkte gesetzt und Aktionen durchgeführt, um die Anzahl der Unfälle im Straßenverkehr so gering wie nur möglich zu halten. Dabei soll das Bewusstsein der Bevölkerung geschärft werden und die Aufmerksamkeit im Straßenverkehr gesteigert werden.

Der „Pedi-Bus“ ist ein weiteres Projekt der Mobilitätszentrale, das gemeinsam mit der Landeshauptstadt Eisenstadt umgesetzt wurde. Dabei werden Gruppen von Kindern zu Fuß von Erwachsenen auf dem Weg zur Schule begleitet und auf das richtige Verhalten im Straßenverkehr geschult. Durch diese Aktion werden bereits die jüngsten Gemeindebürger auf die Gefahren des Straßenverkehrs vorbereitet. Dies ging aus den Interviews hervor.

5 FAZIT

Die Ergebnisse der diesem Beitrag zugrundeliegenden Studie zeigen, dass die regionale Verkehrspolitik durchaus einen beachtenswerten Beitrag zur Realisierung der Vision lebenswerter, gesunder und prosperierender Städte für alle Menschen leisten kann. Sie muss sich dabei an der Verflechtung der verschiedenen Ebenen orientieren. Im Land selbst ist auf ein gutes Zusammenwirken der Landes-, Bezirks- und Gemeindepolitik zu achten, jedoch müssen dabei die Rahmenbedingungen des Bundes und der EU berücksichtigt werden. Um jedoch ein gesamthaft optimales Ergebnis zu erzielen, ist es sinnvoll, die lokale Bevölkerung in konkrete Maßnahmen einzubinden bzw. ihr die Möglichkeit zu bieten, selbst Initiativen zu setzen.

Wie die Ergebnisse gezeigt haben, ist das vielerorts starke Verkehrsaufkommen auf Burgenlands Straßen ein wichtiges Kriterium für die Lebensqualität im Land. Der bereits erfolgte und in Zukunft stattfindende Ausbau des hochrangigen Straßennetzes trägt in hohem Ausmaß dazu bei, dass die betroffenen Lebensräume entlastet werden. Neben den Verbesserungen im Straßennetz sollen auch die auf Landesebene gesetzten

Schwerpunkte in den Bereichen Bahn- und Radverkehr Verbesserungen für die burgenländische Bevölkerung im Verkehrsbereich herbeiführen. Die schwierige Situation rund um den öffentlichen Verkehr in den südlichen Landesteilen stellt eine große Herausforderung für die Entscheidungsträger der unterschiedlichen politischen Ebenen dar, das vorhandene Engagement muss zu entsprechenden Lösungen führen, um die Lebensqualität der Bevölkerung positiv beeinflussen zu können. Im Bereich der Verkehrssicherheit haben sich sowohl Landes- als auch Kommunalebene der Bevölkerung verpflichtet, die zahlreichen Aktivitäten spiegeln dies wider und tragen dazu bei, um das Burgenland zu einer lebenswerten Region zu machen.

Es liegt in der Natur der Sache, dass eine Befragung von Politikern, respektive Trägern der Verkehrspolitik im Ergebnis politische Aussagen generiert. Die gegenständliche Studie soll daher nur ein erster Schritt in Richtung einer umfassenden Darstellung der verkehrspolitischen Situation im Burgenland gewesen sein. Es ist sinnvoll – und daher angedacht – Erhebungen im Bereich der Unternehmen sowie unter der Bevölkerung durchzuführen um ein vollständiges Lagebild zu erreichen.

Der Low-Carbon-Index: Ein Instrument zur Beurteilung der Energieeffizienz städtebaulicher Planungen

Hannah Baltes, J. Alexander Schmidt

(J. Alexander Schmidt, Prof. Dr.-Ing., Universität Duisburg-Essen, Institut für Stadtplanung und Städtebau. Universitätsstraße 15, 45141 Essen, alexander.schmidt@uni-due.de)
(Hannah Baltes, Dipl.-Ing., Universität Duisburg-Essen, Institut für Stadtplanung und Städtebau. Universitätsstraße 15, 45141 Essen, hannah.baltes@uni-due.de)

1 ABSTRACT

Die Nachhaltigkeit und Energieeffizienz einer Stadt wird durch eine Vielzahl von Faktoren geprägt und geformt. Eine optimale effektive Lösung ist nur mit einem multidisziplinären, integrierten Ansatz zu erreichen. Um dabei den Planungsprozess nicht zu komplex werden zu lassen, sind mindestens die Disziplinen von Stadtplanung und Stadtgestaltung, Verkehr und Mobilität, Gebäude und Gebäudetechnik und regenerativer Energieproduktion einzubeziehen. Vor allem aber gilt es, bereits gleich zu Beginn eines Planungsprozesses sämtliche Aspekte zu berücksichtigen, um die Energieeffizienz auf allen Ebenen und in ihrem Zusammenspiel zu erhöhen.

Ein Forschungsprojekt in China/Shanghai zeigt, dass dieser Ansatz sinnvoll und effektiv sein kann, angesichts seiner Komplexität allerdings den Beteiligten gegenüber nur schwer vermittelbar wird - insbesondere Bürgern und Stakeholdern auf der politischen Ebene.

Vor diesem Hintergrund wurde als Planungs- und Bewertungstool der Low-Carbon-Index (LCI) entwickelt, der bei der Bewertung und Planung von Städten, Stadtteilen, Stadtquartieren ebenso wie einzelnen Bauensembles im Hinblick auf die Energieeffizienz und CO2-Reduktion gleichermaßen hilfreich ist.

Bei der Anwendung des LCI fließen die wesentlichen den Energieverbrauch und die CO2-Emissionen determinierenden Größen ein. Leicht ermittelbare Hilfsgrößen dienen der Einschätzung der Bedeutung des Indikators in der konkreten Situation für den Energieverbrauch. Bei der Bewertung muss zwischen quantitativer oder qualitativer Ausprägung eines Indikators (z.B. Energieverbrauch oder Energieverbrauchsdifferenz) und der Bewertung dieser quantitativen oder qualitativen Ausprägung unterschieden werden. Während die quantitative oder qualitative Ausprägung noch objektiv einen realen Sachverhalt beschreibt, erfolgt die Bewertung des Sachverhalts auf einer subjektiven Grundlage. Wissenschaftlich begründet ist das Erstere. Das Letztere, die Bewertung des Sachverhalts, unterliegt hingegen individuellen oder – bei öffentlichen Planungen – politisch legitimierten Grundsätzen und Zielen.

Der LCI arbeitet auf den unterschiedlichen Planungsebenen zwischen dem Maßstab 1:25.000 (Regional- bzw. Stadtentwicklungsplanung) bis zur Realisierungsplanung eines Bauwerks, um jeweils frühzeitig im Hinblick auf die Energieeffizienz bzw. die Reduktion der CO2-Emissionen intervenieren und den Planungsprozess bis hin zur Durchführung begleiten zu können.

Der LCI bleibt trotz des sehr komplexen Wechselwirkungen und der verschiedenen Maßstäbe in Struktur und Bewertung einfach und schnell anwendbar. Dieses unterscheidet den LCI von anderen bereits bestehenden und aufwendigen Zertifizierungsmethoden deutlich.

Derzeit liegt der LCI in der Version 1.0 vor, er wird aber durch die Erkenntnisse aus den verschiedenen Anwendungen laufend weiterentwickelt.

2 EINLEITUNG

Der LCI (Low Carbon Index) ist eine Methode, die entwickelt wurde, um mit geringem Aufwand bestehende Stadtteile, Quartiere und Gebäudegruppen ebenso wie Planungskonzepte in Bezug auf ihre Energieeffizienz und - in einem späteren Schritt - auch in Bezug auf ihren CO2-Ausstoß zu bewerten. Sie wird zunächst für chinesische Megacities ermittelt, soll aber langfristig auch in anderen Erdteilen Anwendung finden können.

Der LCI bewertet die Energieeffizienz / CO2-Effizienz (Energieeinsatz pro Person und Jahr, Energieeinsatz pro Tonnenkilometer und Jahr) in den Themenfeldern Städtebau, Mobilität, Gebäude und regenerative Energieproduktion.

Für jedes der vier Themenfelder wurden jeweils eine Reihe von Kriterien definiert, die auf einer Skala von -2 bis +2 bewertet werden können.

Bei der Anwendung des LCI werden drei Phasen unterschieden: Die erste Phase kann bereits bei einer relativ großmaßstäblichen Planung im Maßstab ab 1:25.000 ansetzen. Hier werden Strukturen und übergeordnete Aspekte einer Planung in den Themenfeldertn Stadt und Mobilität betrachtet.

Für die zweite Phase muss die zu bewertende Planung bereits stärker detailliert sein (Maßstab bis 1:500); für bestehende Quartiere müssen dementsprechend kleinteilige Daten vorliegen. Es werden insbesondere im Bereich Gebäude Details zur Berechnung des Energiebedarfes und der CO2-Emissionen benötigt.

Die 3. Phase (ab 1:500) bezieht sich auf konkrete Detailplanungen während der Realisierung bzw. vor entsprechenden Umbauten. Hier sind die Bereiche Mobilität und Stadtplanung nur noch am Rand vertreten während Gebäude und regenerative Energieproduktion große Bedeutung haben.

3 ZIELE

Ziel ist es, Aussagen zur Energieeffizienz und zum CO2-Ausstoß von Stadtbereichen, Quartieren oder Gebäudegruppen mit einem geringen (finanziellen und zeitlichen) Aufwand zu ermöglichen. Dabei sollen qualitative und quantitative Aspekte gleichermaßen betrachtet und in einer Bewertung zusammengeführt werden.

Die LCI-Methode soll die Energieeffizienz von Planungen nachvollziehbar bewerten, um etwaige Fehlplanungen in frühen Planungsphasen zu erkennen und zu vermeiden helfen. Zudem hilft es bei detaillierten Planungen, Schwachstellen zu lokalisieren und aufzudecken, die bis zur Realisierung geändert werden können.

Mit dem LCI soll kein weiteres Zertifizierungsinstrument eingeführt werden, welches genaue Berechnungen von Energieverbräuchen und CO2-Emissionen aufstellt. Vielmehr ist es ein Instrument, welches hilft, eine erste Einschätzung von Planungen in Bezug auf CO2-Emissionen und Energiebedarfe zu treffen.

Weiterhin gehen aus dem LCI Guidelines hervor, die von Investoren bei der eigentlichen Realisierung beachtet und umgesetzt werden müssen. Diese Guidelines können auch Vertragsbestandteil bei Grundstücksverkäufen in neu geplanten Gebieten werden.

Langfristig sollte angestrebt werden, den LCI gesetzlich als Bewertungsinstrument für alle Planungenvon der Stadtentwicklung bis zur Quartiersplanung heranzuziehen, um bereits in der allerersten Planungsphase Fehlentwicklungen und Planungen, die absehbar einen hohen Energieverbrauch haben werden, zu verhindern.

4 METHODENENTWICKLUNG

Die Methode wird zunächst für die Region Shanghai innerhalb eines Forschungsprogramms entwickelt, soll aber in einem weiteren Schritt auch auf andere Megacities und Regionen übertragen werden können.

4.1 Aufbau des LCI

Die Bewertung eines Plans mit Hilfe des Low Carbon Index ist ein komplexer Ablauf mit einigen iterativen Prozessen (siehe 1). Ausgangspunkt ist ein bestehender Plan, welcher mit Hilfe einer Reihe vorab definierter Kriterien bewertet wird. Dazu wird die bereits angesprochene Bewertungsskala nach Punkte genutzt. Dies ergibt eine Analyse der unterschiedlichen Themenbereiche Stadt, Mobilität, Gebäude und regenerative Energien, welche zu einem Gesamtbild zusammen gefasst wird. Diese Bewertung wird mit den ursprünglichen Zielen der Planung abgeglichen. Sollten sich nun Abweichungen und Unterschiede feststellen lassen, muss die Planung überarbeitet werden. Die Bewertung der einzelnen Kriterien hilft dabei, die Schwachstellen genau zu lokalisieren und schneller zu neuen Lösungsmöglichkeiten zu gelangen. Das Ergebnis daraus ist ein neuer bzw. modifizierter Entwurf, der abermals geprüft und bewertet wird. Dieses Verfahren kann so oft wiederholt werden, bis ein gutes Ergebnis entstanden ist.

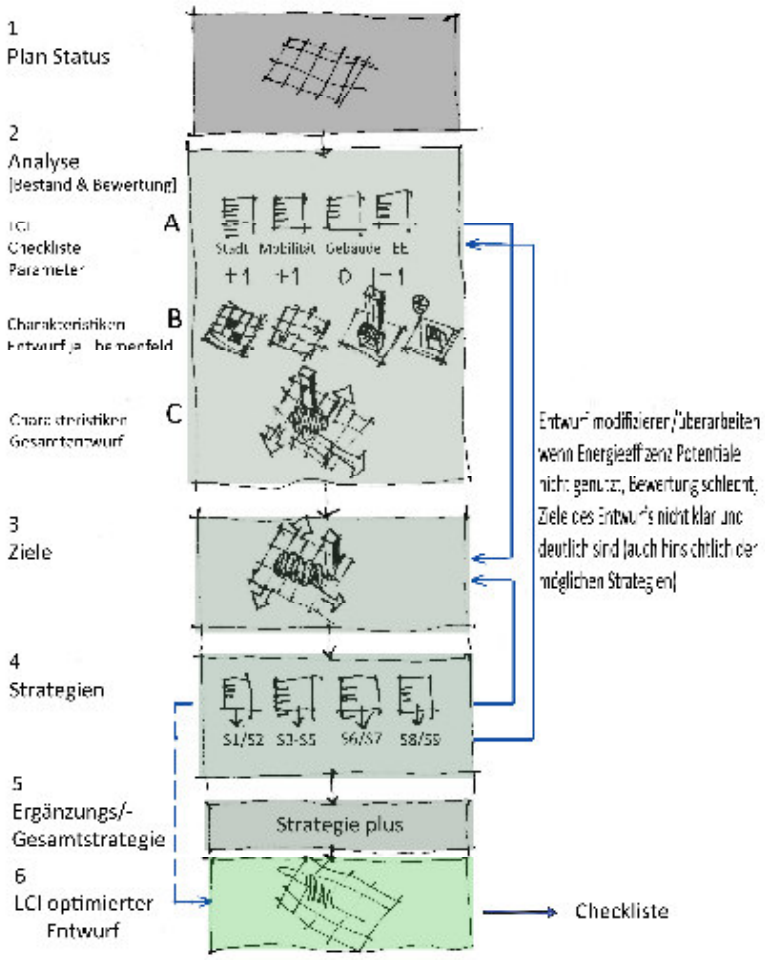

Abbildung 1: Ablauf der Bewertung mit Hilfe des LCI; Quelle: eigene Darstellung

Aus der Bewertung des Entwurfs werden Strategien ermittelt, nach denen die Planung aufgebaut wurde. Dies könnten z.B. im Bereich des Städtebaus „Transit-Oriented-Development“, „Walkability“ oder auch eine „Stadt der kurzen Wege“ sein. Analog dazu gibt es auch Strategien in den anderen Themenbereichen.

Aus den unterschiedlichen Strategien wird anschließend eine Gesamtstrategie für den vorliegenden Entwurf entwickelt, unter der das neu geplante Gebiet entwickelt wird. Der Entwurf muss abschließend an diese Strateige angepasst werden.

Aus dem Entwurf ergeben sich für die eigentliche Umsetzung mit dem Kaufvertrag verknüpfte Guidelines und Checklisten, die von den Investoren und Bauherren eingehalten werden müssen. Diese Checklisten muss während der Realisierung abgearbeitet werden, die Einhaltung wird später von den Verantwortlichen kontrolliert.

4.2 Bewertungsphasen

Wie der Ablauf des LCI zeigt, werden während der Planung eines Gebietes immer wieder neue Bewertungen notwendig. Dies liegt zum einen an der stetigen Verbesserung der Planung und der Anpassung an die Kriterien, zum anderen liegt es daran, dass die Planungen im Laufe des Verfahrens immer stärker detailliert werden. Zu Beginn einer Planung wird auf einem ganz anderen Maßstab gearbeitet als bei der eigentlichen Umsetzung.

Daher wurde der LCI mit seinen Themenfeldern und Bewertungskriterien auf drei Phasen aufgeteilt, die auf unterschiedlichen Maßstabsebenen arbeiten und daher auch unterschiedliche Bewertungskriterien nutzen:

Grundlage von Google Earth und Google Maps

In Phase 1 werden die Grundlagen für die weiteren Planungen gelegt. Es wird auf einem Maßstab zwischen 1:25.000 und 1:10.000 gearbeitet. In dieser Phase steht lediglich das grobe Konzept der Planung im Vordergrund. Daher werden hier ausschließlich die Themenfelder Städtebau und Mobilität bewertet. Es werden Kriterien wie die Standortwahl und die verkehrliche Anbindung an die Stadt betrachtet.

In Phase 2 wird die Planung bis zum Maßstab 1:500 bewertet. Die Planungen sind bereits deutlich konkreter und es können mehr Details bewertet werden. In Phase 2 werden alle vier Themenfelder mit in die Bewertung aufgenommen.

Phase 3 bezieht sich bereits auf die Umsetzung (ab 1:500). Die Bereiche Städtebau und Mobilität spielen nur noch eine untergeordnete Rolle, da auf diesem Maßstab kaum noch Maßnahmen getroffen werden können, die großen Einfluss auf den Energieverbrauch und die CO2-Emissionen haben. Das größte Einsparpotential beim Energieverbrauch liegt in diesem Maßstab bei der Gestaltung und technischen Ausstattung der Gebäude. Zudem kann die Nutzung erneuerbarer Energien eine deutliche Einsparung bei den CO2-Emissionen bewirken.

Im Überblick werden innerhalb der drei Phasen folgende Kriterien mit unterschiedlichen Unterpunkten mit in die Bewertung aufgenommen (Abb. 2).

5 BEWERTUNGSSKALA

Die Skala der Bewertung soll von +2 Punkten bis -2 Punkte reichen. Damit stehen 5 Punkte für eine Bewertung zur Verfügung. Diese relativ einfache Einteilung von sehr gut bis sehr schlecht begründet sich aus dem Umstand, dass der LCI eine relativ grobe Einteilung benötigt. Eine feinere Messskala würde den überschlägigen Einschätzungen zur einfachen Anwendung nicht gerecht werden.

Damit muss die nächste Frage beantwortet werden, welche Planung die obere Grenze (+2 Punkte) erhalten soll und welche Planung umgekehrt die untere Grenze (-2) markiert. Grundsätzlich soll dabei gelten, dass sich die zu entwickelnde Bewertungsskala an der Frage orientieren muss, wie viel die Planung zum Erreichen des vorgegebenen Klimaschutzzieles beiträgt, d.h. welcher Energiebedarf bzw. welche CO2-Emissionen im betreffenden Jahr zu erwarten sein wird.

Festgelegt wurde bereits in den vorhergegangenen Abschnitten, dass eine Planung die maximale Punktezahl erhalten soll, wenn sie erwarten lässt, dass das Effizienzsteigerungsziel erreicht wird. Die Frage ist, welche Planung mit 0 Punkten belegt wird und welche gar mit negativen Punkten bewertet werden muss. In der gegenwärtigen Testphase LCI 1.0 wird der Referenzfall mit 0 Punkten belegt. Die Praktikabilität dieser Festlegung muss selbstverständlich an Beispielen verifiziert werden. Es macht aber Sinn, den Referenzfall, demgegenüber die Verbesserung erreicht werden soll, als Ausgangspunkt aufzufassen. Wenn also die Planung nicht zu einer Verbesserung führt, kann sie auch nicht mit mehr als 0 Punkten bewertet werden.

Aus dieser Festlegung folgt automatisch auch, dass danach die -2-Grenze festliegt. Der Abstand von 0 zu +2 soll gleich groß sein wie der Abstand von 0 zu -2.

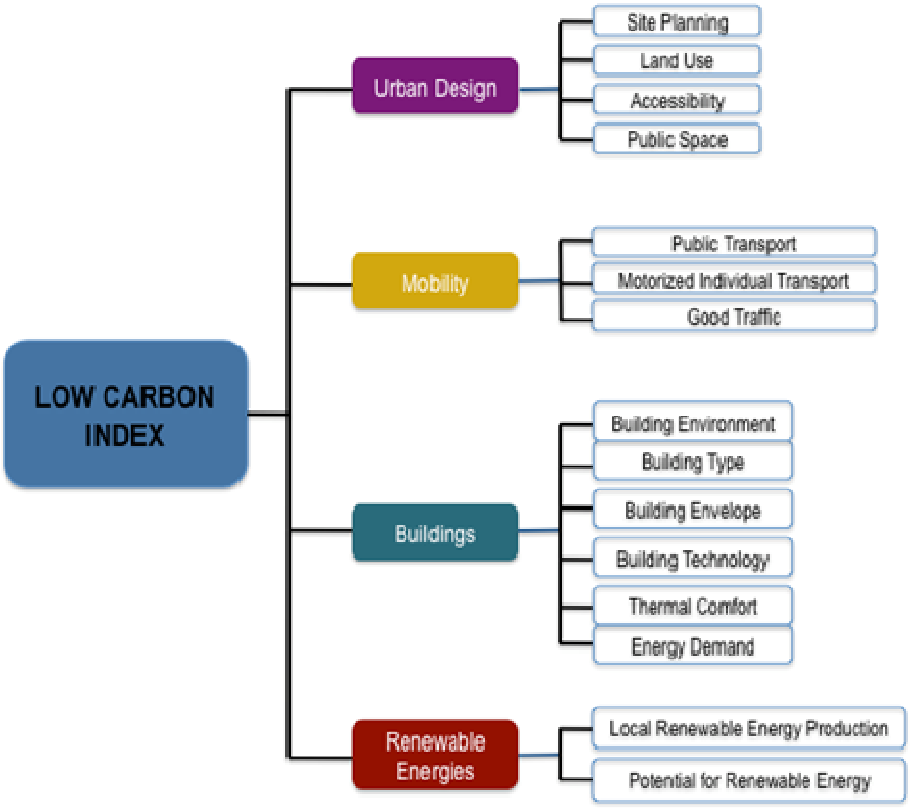

Abbildung 2 Kriterien des LCI nach Themen; Quelle: eigene Darstellung

6 PROBLEMATIK

Die Problematik bei der Entwicklung des LCI liegt vor allem bei der Bestimmung der Bewertungskriterien bzw. ihrer Bewertungsskala. Um die Bewertung eines Low Carbon Indexes festzulegen, ist es notwendig, zunächst zu definieren, was Low Carbon eigentlich bedeutet. Dies ist insbesondere bei der Arbeit in China bzw. in Shanghai besonders schwierig, da es kaum Referenzwerte oder Referenzen aus der Literatur gibt. Die Werte aus europäischen Studien sind darüberhinaus nicht vergleichbar, denn sowohl die Charakteristika der Städte als auch das Richtwerte sind sehr unterschiedlich.

Zudem müssen qualitative und quantitative Kriterien in ein Bewerttungsschema eingepasst werden. Die Problematik liegt insbesondere darin begründet, dass die quantitativen Kriterien berechnet werden können und somit die Einordnung in die Bewertungsskala leicht fällt. Die qualitativen Kriterien müssen jedoch abgeschätzt werden, was die Methode angreifbar macht und zudem die Bewertung in Teilen willkürlich erscheinen lässt. Dazu ist es besonders wichtig, Erfahrungen mit der Anwendung des LCI zu sammeln und diese in die Bewertung einfließen zu lassen.

7 WEITERES VORGEHEN

Der Low Carbon Index ist im Rahmen eines Forschungsprojektes in Shanghai entwickelt worden. Hier wird er zur Zeit an zwei verschiedenen Modellprojekten angewendet und erprobt. Ein Gebiet ist eine Low Carbon Business Area. Das andere Gebiet ist ein großes Wohngebiet für sozial schwächer gestellte Menschen, annähernd vergleichbar mit dem deutschen Sozialwohnungsbau.

Bis zur Konferenz werden die ersten Ergebnisse der Pilotgebiete vorliegen. Außerdem werden die Untersuchungen für Referenzgebiete in Shanghai begonnen haben. Dieses werden präsentiert. Dabei werden sich die Schwachstellen der Methode und des Bewertungsschemas zeigen. Im Verlauf der weiteren Anwendung wird die Methode ständig verbessert und aktualisiert.

1 ABSTRACT

In Zeiten des WebGIS und des Web 2.0 entstehen für Planer beinahe täglich neue Daten und Instrumente, die frei kombiniert werden können. Diese sollten bereits heute von Planern nicht nur erkannt, sondern auch aufgegriffen, zusammengesetzt und weiterentwickelt werden – denn es kann heute bei der Entwicklung neuer Konzepte nicht mehr darum gehen „das Rad neu zu erfinden“. Wie ein Eichhörnchen kann der Planer sich auf die Suche nach bestehendem Material begeben und dieses zusammen tragen. Mit wenig Aufwand kann so innerhalb kürzester Zeit eine spezifische Sammlung an Informationen und Instrumenten „angehäuft“ werden. Dienlich kann diese gezielte Sammlung in nahezu allen Planungsbereichen sein. Zwei Beispiele, die die Effizienz und den Nutzen einer solchen „Ansammlung“ zeigen, sollen an dieser Stelle dargstellt werden: Zum einen ein Monitoringsystem, bei dem es darum geht Baulandpotenziale im Innenbereich zu überwachen um eine Ausweisung im Außenbereich zu verhindern. Zum anderen wird anhand eines Beispiels aus der Tourismusbranche aufgezeigt, wie mit dieser Methode sowohl die Touristen als auch die Bewohner der Destination und deren Planer davon profitieren können. Beide Projekte zeigen, wie Planer als „Eichhörnchen“ die Städte der Zukunft, auf einfache Art und Weiße, lebenswerter gestalten können und sich nebenbei immer wieder neue „Nüsse“ für ihre nächste „Ansammlung“daraus ergeben.

2 EINLEITUNG

2.1 Die Notwendigkeit des Sammelns

Zunächst stellt sich die Frage, warum der Planer sich überhaupt an der Sammelwut beteiligen soll - zumal immer mehr Unternehmen mit ihrer blinden Sammelwut negativ auf sich aufmerksam gemacht haben. Die Antwort liefert ein altes, aber doch bewehrtes Sprichwort: „Wissen ist Macht!“. Wissen erlangt der Planer jedoch nur durch eine umfassende Informationsbasis, die wiederum aus Daten generiert wurde. Ein einfaches Beipiel aus der Praxis verdeutlicht dies: Die Bestandsaufnahme, die vor jeder Planung durchgeführt werden sollte, ist ebenfalls nichts anderes als das Sammeln von Daten und deren anschließende Auswertung. Je mehr Daten dem Planer vorliegen, desto mehr Informationen kann er später daraus generieren. Die Planung wird dadurch weniger anfällig für Fehler oder Komplikationen. Im Endeffekt gilt damit: Je umfassender die Datengrundlage (Sammlung) umso besser kann geplant werden. Denn nur so kann aus guten Daten „Information“ werden, die anschließend zu „Wissen“ übergeht, mit dem ein (planerischer) „Mehrwert“ generiert werden kann. Dies ist die primäre Aufgabe von Planungsinformationssystemen: Sie sollen Wissen generieren und bereit stellen, um Planungsdiskurse zu unterstützen und Planungsentscheidungen herbeizuführen [Streich 2005:248]. Dabei sollten Informationen und Wissen unter anderem nach folgenden Gesichtspunkten aufgearbeitet werden [nach Kaiser et al. 1995:90]: Die Beschreibung historischer Abläufe und und der gegenwärtigen Situation, die Vorrausschätzung zukünftiger Entwicklungen, und vor allem das Beobachten (das „Monitoring“) also die Erfassug und Interpretation von Veränderungen und deren Diagnose und Bewertung.

2.2 Das Objekt der Begierde

Wie zuvor erläutert wurde, lohnt sich die Sammlung vieler Daten – doch diese stellen nur einen Teil dessen dar, was sich für den Planer zu sammeln lohnt. Denn neben den Daten können auch frei verfügbare Softwaretools als Arbeitswerkezug mit den zugehörigen Methoden und der Anwender, der Mensch an sich, Daten liefern, Daten generieren oder in einen neuen Kontext stellen.

Geoinformationssyteme sind aus dem heutigen Planungsalltag nicht mehr weg zu denken. Sie binden Geodaten in eine anwendbare Struktur und erleichtern so unseren Alltag. Im Grunde könnte man bereits hier sagen, dass es sich um Sammeln handelt, denn schließlich werden die Geodaten in einer Datenbank „gesammelt“. Neben den Geodaten besitzen Geoinformationssysteme jedoch noch drei weitere

Komponenten: Hardware, Software und den Anwender. Das interessante ist nun, auch in den beiden letzt genannten zu sammeln. Im Folgenden wird dies an zwei praktischen Beispielen aufgezeigt. Die „Sammelschwerpunkte“, sprich das „Objekt der Begierde“, ist dabei recht unterschiedlich.

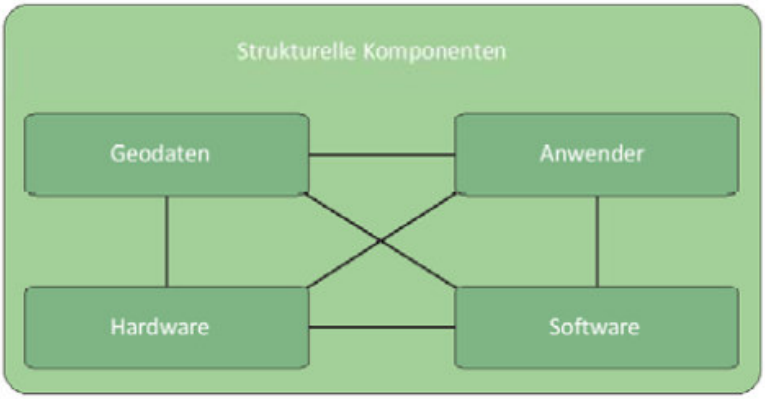

Abb. 1: Strukturelle Komponenten eines Geoinformationssystems

3 ARBEITEN ODER ARBEITEN LASSEN? DIE ZWEI MÖGLICHKEITEN DES SAMMELNS!

Die Herangehensweise des Sammelns unterscheidet sich in den beiden Beispielen von Grund auf. Das erste Beispiel erläutert die Sammlung von Daten „per Hand“. Das heisst, der Planer generiert die benötigten Daten selbst. Im Folgenden wird diese Vorgehensweise als „aktives“ Sammeln beschrieben. Das zweite Beispiel hingegen, veranschaulicht, wie durch Social Networking die begehrten Informationen durch die Anwender generiert werden. Diese Vorgehensweise wird als „passives“ Sammeln beschrieben, da der Planer hier nach erfolgreicher Einrichtung des Systems nur noch auf den Input der Anwender warten muss. Das sogenannte Crowd Sourcing kann, bei richtiger Anreizschaffung, die Zukunft der Datenbeschaffung für die Planung stark verändern.

3.1 Aktives Sammeln am Beispiel eines Flächenmonitoring-Systems

Wie bereits erwähnt, nimmt der Planer bei dem Flächenmonitoring-System eine aktive Rolle als Sammler ein. Er muss sich im Vorfeld auf die Suche nach den passenden Daten begeben und diese sinnvoll miteinander kombinieren. Im Rahmen dieses Projektes bezieht sich der Sammelprozess hauptsächlich auf die Auswahl der richtigen Softwarekomponenten sowie die Erstellung einer Geodatenbank, in welcher die Flächeninformationen gesammelt werden. Aufbauend auf dieser Sammlung ist ein WebGIS basiertes Flächenmonitoring-System entstanden, welches den Flächenverbauch langfristig reduzieren soll.

3.1.1 Problemstellung und Zielsetzung des Projektes

Siedlungswachstum und –schrumpfung liegen heute in deutschen Kommunen oft nah beieinander – obgleich es sich hierbei um konträre Entwicklungen zu handeln scheint. Doch während in vielen Kommunen die Innenstädte zunehmend von Leerständen, Baulücken und Brachen geprägt sind, werden im Außenbereich Neubaugebiete ausgewiesen. Etwa 100 ha werden so bundesweit jeden Tag an natürlicher Landschaft verplant oder zum Bau freigegeben. Diese Entwicklung muss zusätzlich im Kontext der schrumpfenden und zunehmend überalterten Bevölkerung gesehen werden.

Die Problematik des zunehmenden Flächenverbauchs wird auf Bundesebene unter anderem in der Nationalen Nachhaltigkeitsstrategie behandelt. Hier ist das Ziel verankert, die Flächeninanspruchnahme bis zum Jahr 2020 auf 30 ha zu reduzieren. Als unterstützendes Leitbild ist in diesem Kontext die Flächenkreislaufwirtschaft zu verstehen. Diese liegt einer Strategie zu Grunde, bei der die systematische Abschöpfung von Potentialen der Bestandsentwicklung und eine Inwertsetzung von Brachflächen im Vordergrund stehen. Die Flächenkreislaufwirtschaft ist das langfristige Ziel der nachhaltigen Siedlungsentwicklung. Ein Etappenziel auf diesem Weg ist das Flächenmanagement, welches ein Instrument zur Steuerung und Regulierung der künftigen Nutzungen und Flächeninanspruchnahmen ist. Flächenmanagement baut auf den umfassenden Vorarbeiten des Flächenmonitorings auf. Dieses Instrument ermöglicht eine Erfassung, Beobachtung und Dokumentation von Potentialflächen. Daher ist Flächenmonitoring als der wesentliche Startpunkt hin zu einem Flächenmanagement bzw. langfristig zu einer Flächenkreislaufwirtschaft zu sehen. Das Flächenmonitoring-System, das im Rahmen dieses Projektes

entwickelt werden sollte, bietet den Gemeinden ein kostengünstiges Instrument mit welchem Sie die gesammelten Informationen übersichtlich erfassen und aufbereiten können, um so einem weiter wachsenden Flächenverbrauch entgegenzuwirken. [KEBBEDIES, et.al., 2008]

3.1.2 Aufbau des Flächenmonitoring-Systems

Für den Aufbau des Flächenmonitoring-Systems muss der Planer als Sammler aktiv werden. Hierbei muss er die unterschiedlichsten Daten zusammensuchen und miteinander kombinieren. Diese Daten lassen sich in zwei unterschiedliche Kategorien bzw. Sammlungen unterscheiden. Die erste Sammlung stellt dabei den Aufbau des WebGIS dar. Zunächst muss eine passende Benutzeroberfläche für das WebGIS des Flächenmonitoring-Systems gefunden werden. Hierfür wurde die mapbender Software zurückgegriffen, da diese alle benötigten Funktionen mit sich bringt. Da der mapbender allerdings alleine nicht lauffähig ist wurden noch weitere Softwarekomponenten gesammelt werden. Hierzu zählen neben dem Webserver Apache, die PostgreSQL Datenbank sowie die Erweiterung Postgis. Aufbauend auf den nun vorhandenen Softwarekomponenten wurde im Rahmen des Projektes ein Flächenmonitoring-Portal für die Verbandsgemeinde Altenglan in Rheinland-Pfalz errichtet. Bevor mit der Ansammlung der eigentlichen Inhalte begonnen wurde musste noch eine Kartengrundlage gefunden werden. Eine passende Liegenschaftskarte wurde durch einen WMS-Dienst des Landesvermessungsamtes Rheinland-Pfalz (LVermGeo.RLP) gefunden. Für die Einbindung eigener Karteninhalte wurde ebenfalls ein eigener WMS-Dienst eingerichtet, wobei hierfür auf die UMN MapServer Software zurückgegriffen wurde.

Nachdem die erste Sammlung komplettiert und die technische Infrastruktur des WebGIS aufgebaut wurde, kann mit der zweiten Datenansammlung begonnen werden. Diese enthält die eigentlichen Inhalte des WebGIS. Da sich das Projekt auf ein Flächenmonitoring-System für Baulücken bezieht, ist das Objekt der Begierde nun zunächst die Baulücke ansich. Nachdem zunächst der Begriff der Baulücke definiert wurde, konnte ein passendes System zur Filterung der Baulücken erstellt werden. Dieses war notwenig, da zwar alle benötigten Daten vorhanden, aber nicht frei verfügbar waren, d.h. sie konnten nur behördenintern bearbeit werden. Ein weiterer Grund für die Erstellung einer eigenen Sammlung war, dass sich bestimmte Daten auf grund unterschiedlicher Formate nicht miteinander kombinieren liessen. Nachdem ein passendes Filtersystem für die Baulücken erstellt wurde, liessen sich diese schnell identifizieren. Neben den Flächen an sich mussten diese noch mit Attributen beschrieben werden. Hierfür wiederum waren zum einen die Open Source Software QuantumGIS sowie bestehende WMS-Dienste des LVermGeo.RLP hilfreich.

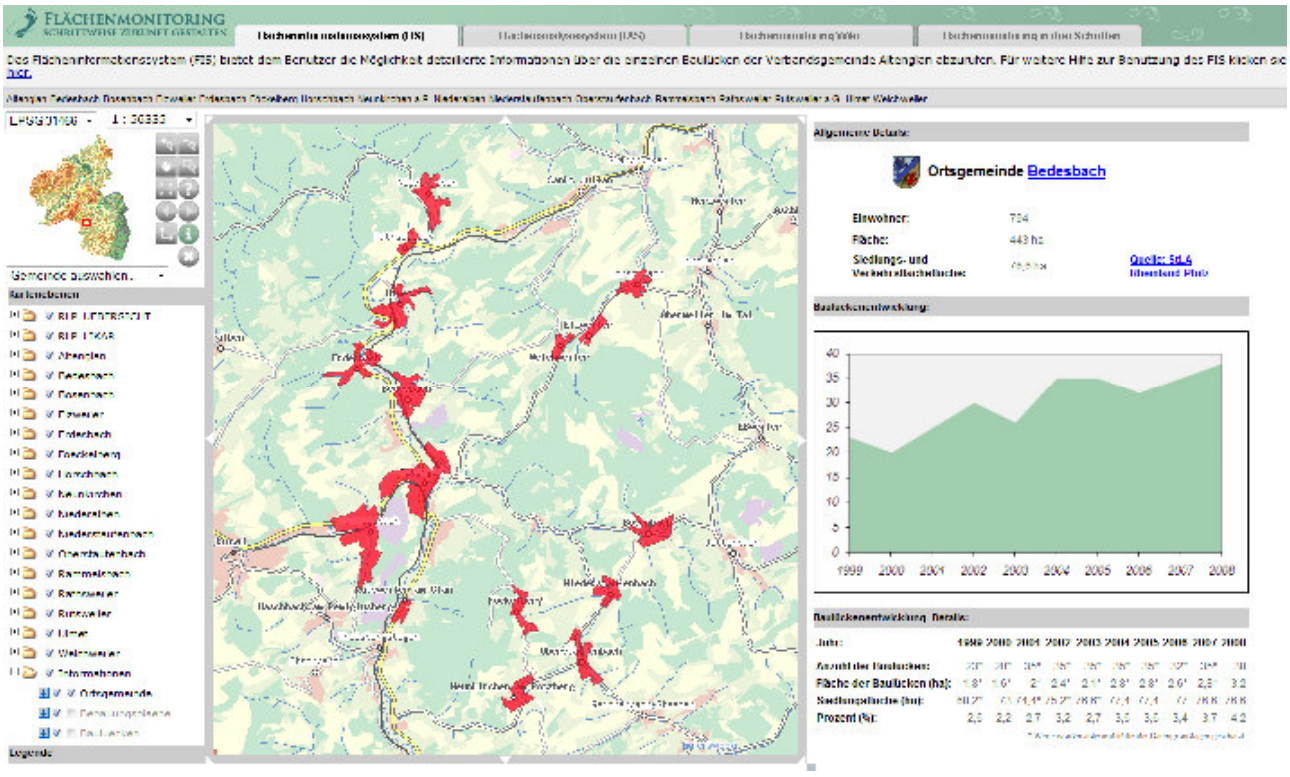

Abb. 2: Baulückenentwicklung der Ortsgemeinde Bedesbach

Nachdem nun alle notwendigen Daten gesammelt wurden konnten diese in das WebGIS, welches unter http://flaechenmonitoring.arubi.uni-kl.de erreichbar ist, eingebunden werden. (Vgl. Abb. 2,3,4)

Durch eine kontinuierliche Aktualisierung und Fortschreibung der Daten ist es der Gemeinde möglich ihre Flächenpotentiale in Form von Baulücken zu erfassen. Werden die Daten über einen längeren Zeitraum gesammelt kann die Gemeinde Statistiken über ihre Baulückenentwicklung erstellen (Vgl. Abb. 2) und darauf aufbauend ihr weiteres Handeln anpassen.

Das bestehende System lässt sich problemlos zu einem behördeninternen Flächenanalysesystem (FAS) erweitern. Dieses bietet der Gemeinde die Möglichkeit ihre Flächenpotentiale weiter zu analysieren. Auf grund von sensiblen Daten ist dieses durch ein Passwort geschützt und nicht öffentlich zugänglich. Der Gemeinde stehen hier zusätzliche Analysewerkzeuge zur Verfügung mit denen es möglich ist ihre Flächeninanspruchnahme gemäß der Nationalen Nachhaltigkeitsstrategie zu reduzieren. Hierzu werden die bestehenden Baulücken je nach ihrer Verfügbarkeit in zwei Kategorien unterteilt, unterschiedlich gewichtet und mit dem Schwellenwert des Regionalen Raumordnungsplanes verrechnet. Durch diese Verrechnung lässt sich eine Handlungsempfehlung für die weitere Entwicklung der Gemeinde ableiten. Sind so z.B. noch genügend Flächenpotentiale in Form von Baulücken vorhanden ist von einer neuen Baulandausweisung abzuraten.

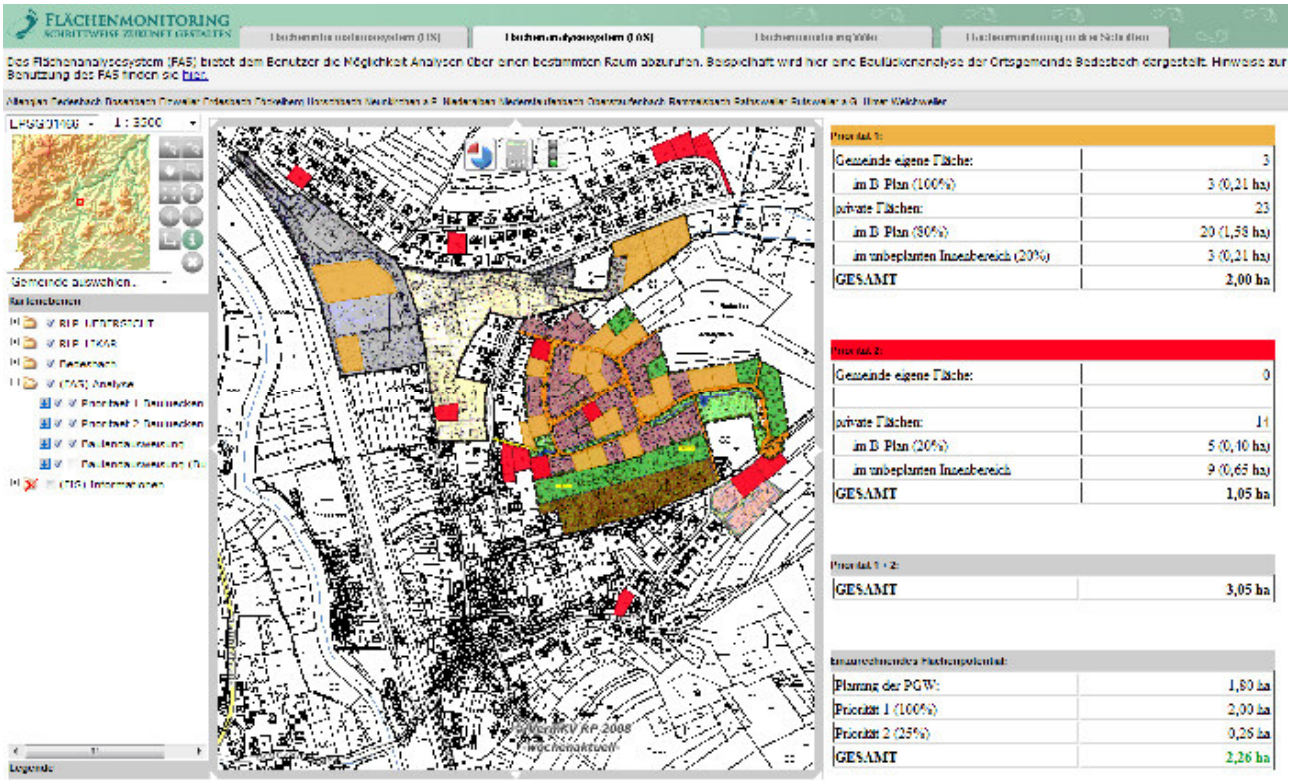

Abb. 3: Flächenpotentialberechnung des FAS

Neben dem behördeninternen FAS lässt sich auf Grundlage der zuvor gesammelten Daten ein Flächeninformationssystem (FIS) einrichten. Dieses bietet der Gemeinde vor allem die Möglichkeit, der Öffentlichkeit allgemeine Informationen über die Baulücken zur Verfügung zu stellen. So können interessierte Anwender, welche z.B. auf der Suche nach einem Baugrundstück sind, sich detailliert über alle für Sie in Frage kommenden Flächen informieren. Der Anwender kann so z.B. die genaue Größe des Grundstücks, den Preis pro m² oder die Flurstücksnummer erfahren (Vgl. Abb. 4). Wichtig hierbei ist, dass aus Datenschutzgründen keine persönlichen Informationen, wie z.B. die Namen der Grundstückseigentümer, veröffentlicht werden.

Das Beispiel des Flächenmonitoring-Systems zeigt, wie das Sammeln von Daten in mehrfacher Hinsicht hilfreich für den Planer und die Gemeinde sein kann. Zum einen können durch die gesammelten Daten und deren Kombination nützliche Informationen für die Gemeinde und die Bevölkerung generiert werden, welche es der Gemeinde ermöglichen kann aktuell nicht oder fehlgenutze Flächen wiederzubeleben. Zum anderen kann durch die Erweiterung des FAS die aktuelle Situation der Baulücken besser erfasst und

analysiert werden, wodurch eine ggf. unnötigen Flächeninanspruchnahme im Aussenbereich vermieden werden kann. [KEBBEDIES, et.al., 2008]

Durch eine Einbindung der Daten in bestehende Portale wie z.B. das Geoportal Rheinland-Pfalz (www.geoportal.rlp.de), kann eine flächendeckende Sammlung angelegt und somit eine Grundlage für ein landesweites Flächenmonitoring geschaffen werden. Das Geoportal Rheinlandpfalz ist eine eine Informations- und Kommunikationsplattform für Geodaten, Geoinformationen und Geodienste in Rheinland-Pfalz, das von allen Kommunen des Landes genutzt werden kann.

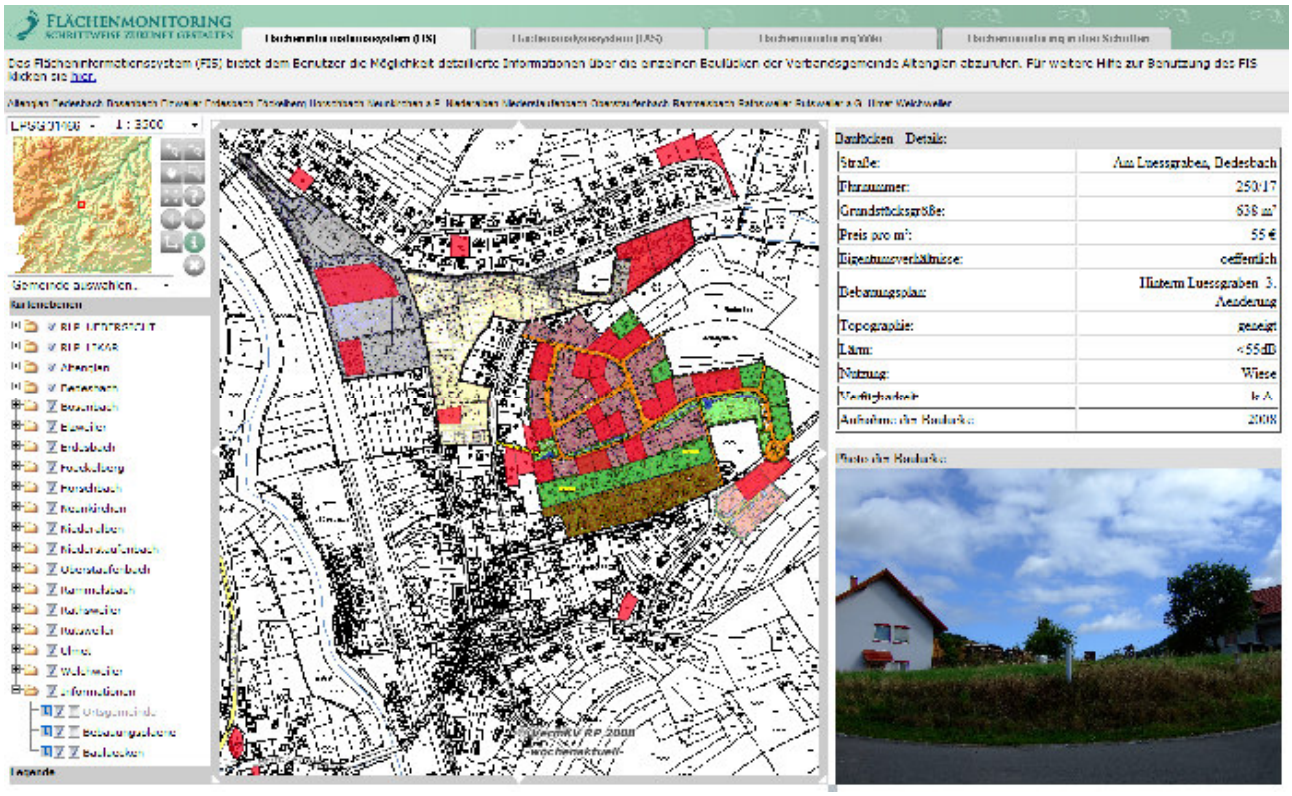

Abb. 4: Das Flächenmonitoring-System als öffentliches Flächeninformationssystem (FIS)

3.2 Passive Sammeln am Beispiel eines Social Networks

Das zweite Beispiel in diesem Rahmen ist ein touristisches Social Network, das für die Stadt Alexandria in Ägypten entwickelt wurde. Im Grunde genommen sind Social Networks nichts anderes als ein gigantischer Pool an Informationen – je nach Bereich in dem das Netzwerk angesiedelt ist (Kontaktpflege, Wandern, Fotos etc.), handelt es sich folglich um unterschiedliche Daten. Touristische Social Networks sind deshalb in diesem Zusammenhang so interessant, weil sie Geoinformationen generieren- schließlich ist jedes auf FlickR lokalisierte oder auf Qype (www.qype.de) bewertete Restaurant nichts anderes! Viele dieser Netzwerke sind daher im Grunde auch als Geoinformationssysteme zu verstehen. Im Gegensatz zu dem zuvor aufgeführten Beispiel des Flächenmonitoring-Systems müssen Planer hier jedoch nicht selbst mühsig Daten eingeben. Die aus der Menge generierten und damit Passiv gesammelten, Daten (Stichwort „Crowed Sourcing“) können direkt verwendet werden. An dieser Stelle kann nun noch einen Schritt weiter gegangen werden: Durch die geschickte Erstellung eines eignen Social Networks können Städte, bzw. Destinationen allgemein, gezielt Informationen für Planungsentscheidungen erzeugen. Wie einfach diese Idee umzusetzen ist sollte im Rahmen eines Experimentes namens „Alexplore“ in der Mittelmeermetropole Alexandria getestet werden. [PICH, 2009]

3.2.1 Problemstellung und Zielsetzung des Projektes „Alexplore“

Social Networking ist mittlerweile in nahezu alle Lebensbereich eingedrungen. Schon lange geht der Nutzen darüber hinaus, den Kontakt mit ehemaligen Schulfreunden aufrecht zu erhalten. Vor allem im Geschäftsleben (z.B. Xing) und im Bereich des Tourismus haben sich die Netzwerke bewährt. In Letzterem wird dabei in Form des bereitgestellten Contents eine Fülle an Informationen generiert, die unsere Städte beschreiben und auch analysieren. Es ist daher eine logische Schlussfolgerung, dass die Planer dieser Städte

sich mit dieser Materie beschäftigen sollten. Dabei ist es jedoch nicht nur wichtig, sich aktiv in den Austausch einzubringen, sondern auch die daraus entstehenden Potentiale zu erkennen und zu nutzen. So entstehen in den Netzwerken beispielsweise Geoinformationen, die für die Planung elementar sein können. Durch den zunehmenden Einsatz mobiler Endgeräte (Stichwort: Mobile Social Networking) werden diese generierten Daten zudem immer aktueller und die Anwendung benutzerfreundlicher. Vorteile können dabei für alle entstehen: Touristen, Planer, Stadtverwaltungen und auch die lokale Bevölkerung. Die Schlüsselrolle für das Aufgreifen dieser Potentiale besitzen die Planer der Städte. Sie sind es, die in der Verantwortung stehen, die Potentiale zu erkennen und sie sowohl für ihre Gäste wie auch Bewohner der Stadt, verfügbar zu machen. Diese Mühe lohnt sich, denn Social Networking birgt ohne jeden Zweifel die Chance einen Beitrag zur nachhaltigen Verbesserung oder Wahrung der Qualität unserer Städte beizutragen.

Die in Folge von Social Networking entstehenden Potenziale werden bislang aber noch zu wenig erkannt oder gar genutzt. Vor allem im Bereich touristisch relevanter Netzwerke können äußerst hilfreiche Informationen generiert werden. Zum Teil sind diese bereits vorhanden und müssen lediglich erkannt werden, zum anderen bieten die Portale eine geeignete Basis um gezielt Informationen nach Bedarf zu gewinnen. Ziel des Projektes war es die Potentiale, die in Folge des Social Networking im Tourismus entstehen, aufzuzeigen und darzulegen in wie fern diese von Planern bereits aufgegriffen und verwendet werden können. [PICH, 2009]

Aufbau des Social Networks

Bei näherer Betrachtung touristisch relevanter Social Networks fällt rasch auf, dass sich zwei Trends herauskristallisieren: Zum einen wird die Verortung der Informationen (z.B. Fotos im Portal FlickR, Videos auf YouTube oder auch Wikipedia-Artikel) immer wichtiger und zum anderen haben die Netzwerke die Potentiale der mobilen Nutzung erkannt und darauf (zum Teil) reagiert. Beide Trends haben dabei einen großen Vorteil: Wie bereits zuvor erwähnt, werden durch die Verortung des Contents Geoinformationen erzeugt – Mobile Social Networking macht diese zusätzlich „top aktuell“. Entscheidend ist dies in diesem Zusammenhang vor allem bei Bewertungen. Diese werden nun nicht mehr drei Wochen nach dem Urlaub ins Portal eingegeben, sondern direkt wärend des Restaurantbesuchs. So können die tatsächlich aktuell vorhandenen Emotionen „aufgefangen“ werden, ohne dass sie durch übrige Erfahrungen des Urlaubs verfälscht werden. Zudem besteht so die Möglichkeit eine größere Bandbreite an Daten zu erhalten, da die Bewertung vom Touristen nicht vergessen wird. (Vgl. RUFFING, 2009] Da in das zu entwickelnde Netzwerk Bewertungen eingebunden werden sollten, war es ein Ziel dieses Netzwerk auch auf Smartphones nutzbar zu machen.

Eine weitere Determinante gab die Stadt Alexandria selbst vor. Die ägyptische Mittelmeerstadt, besitzt kaum Touristen aus dem Ausland – obgleich sie durchaus das Potenzial hierzu hätte: Lange Sandstrände, türkisblaues klares Meer und Spuren des „Alten Alexandrias“ machen die Stadt zu einer Interessanten Destination. Hinzu kommt, dass das 20. Jahrhundert die Stadt zu einem Schmeltigel der Kulturen gemacht hat. Noch heute ist der griechische, englische und italienische Einfluss in der Stadt spürbar. Das größte Problem ist jedoch recht simpel: Niemand weiß das alles außerhalb der Landesgrenzen oder gar in Europa. Alexandria wird meist von den großen ägyptischen Zielen, allen voran Hurghada und Assuan, überschattet. Die meisten Reisebüros haben die Stadt allenfalls als „Abstecher“ von Kairo aus oder im Rahmen einer Mittelmeerkreuzfahrt im Programm. Folglich kommt wohl kaum jemand auf die Idee, Alexandria zu besuchen. Ein weiteres Ziel des Portals war es daher auf die Stadt aufmerksam zu machen und ausgiebig über sie zu informieren. Zudem sollte dort auch die Angst vor einem individuellen Besuch der Stadt (also nicht im Zuge einer Pauschalreise) gemildert werden.

Auf der Basis dieser definierten Determinanten wurde anschließend das Portal „Alexplore“ entwickelt. Der Name setzt sich dabei aus der Abkürzung Alexandrias (Alex) und dem englischen Verb „to explore“, was auf Deutsch soviel bedeutet wie „erforschen“ oder „erkunden“, zusammen. Genau dazu soll mit Hilfe des Portals motiviert werden: Alexandria zu erkunden, denn es ist eine Stadt, die eine Vielzahl erlebnisreicher Momente bereit hält - sofern sich die Touristen darauf einlassen.

Alexplore besteht sowohl aus einem „normalen“ Webauftritt als auch aus einer mobilen Anwendungsmöglichkeit. Der Webauftritt wurde mit Hilfe des Content-Management- artigen Blog-Systems Wordpress (www.wordpress.org) aufgebaut. Die Nutzung eines Blogs als Basis hat den Vorteil, dass er leicht zu erstellen und pflegen ist. Zudem kann problemlos eine Community erstellt und verwaltet werden.

Neben verschiedenen Informationskategorien, die alle von der Community mitgestaltet werden können, gibt es eine Sidebar. Diese dient hauptsächlich der Vernetzung mit weiteren Social Networks, wie FlickR, YouTube oder Facebook. Das eigentliche Kernelement der Seite ist jedoch die „AlexInfoMap“, die auf GoogleMaps basiert. Hier ist es für jeden, jederzeit möglich Content einzuzufügen, der direkt für alle anderen Nutzer der Seite verfügbar ist. Dies birgt natürlich das Risiko fehlerhafter, „unpassender“ oder schlicht illegaler Informationen. Daher gibt es jeweils eine Unterscheidung in Community- und Official-Layer. Das heißt jeder der Layer ist doppelt vorhanden. Die Layer entsprechen einzelnen, für den Touristen interessanten, Kategorien, wie beispielsweiße Hotels, Strände oder Shoppingmöglichkeiten. (Vgl. Abb. 5)

Abb. 5: Die AlexInfoMap ist das Zentrum von Alexplore

Mit Hilfe eines entsprechenden PlugIns wird Alexplore für Smartphones optimiert. Zu Nutzung der AlexInfoMap müssen jedoch die Layer als ZIP-Paket heruntergeladen und über die GoogleMaps-Applikation auf dem Smartphone geöffnet werden – ein großes Manko, da hierdurch die Aktuallität der Daten verloren geht. Zur Nutzung der top aktuellen Daten muss daher (noch) die unangepasste Seite auf dem Smartphone verwendet werden. Zur Nutzung der AlexInfoMap bedarf es jedoch einiges an Fingerspitzengefühl (Vgl. Abb. 7).

Entscheidend für das eigentliche Datensammeln sind die unterschiedlichen Bewertungstools, die an mehreren Stellen angebracht wurden. Zum einen gibt es jeweils am Ende der Wordpress-Seiten einen „MicroPoll“, zum anderen kann jeglicher Content der AlexInfoMap bewertet werden. Hierzu werden in den Official-Layern ebenfalls MicroPolls verwendet. Die Bewertung des Contents der Community-Layer wurde hingegen selbst programmiert. Hierzu diente eine entsprechende Vorlage aus dem Internet, die für diese Zwecke modifiziert wurde. Dies ist natürlich weitaus aufwendiger als die Nutzung der MicroPolls, die recht einfach in einem Internetportal erstellt und über einen Einbettungscode integriert werden können. Allerdings bietet es auch mehr Möglichkeiten. Da die Möglichkeit des Hinzufügens von Content ohnehin selbst programmiert bzw. ebenfalls auf Basis einer Vorlage modifiziert werden musste, bot sich an dieser Stelle der Versuch an. Mit bis zu fünf Sternen können so vier Kriterien (Wohlfühlfaktor, Sauberkeit, Preise, Service) bewertet werden. (Vgl. Abb. 6)

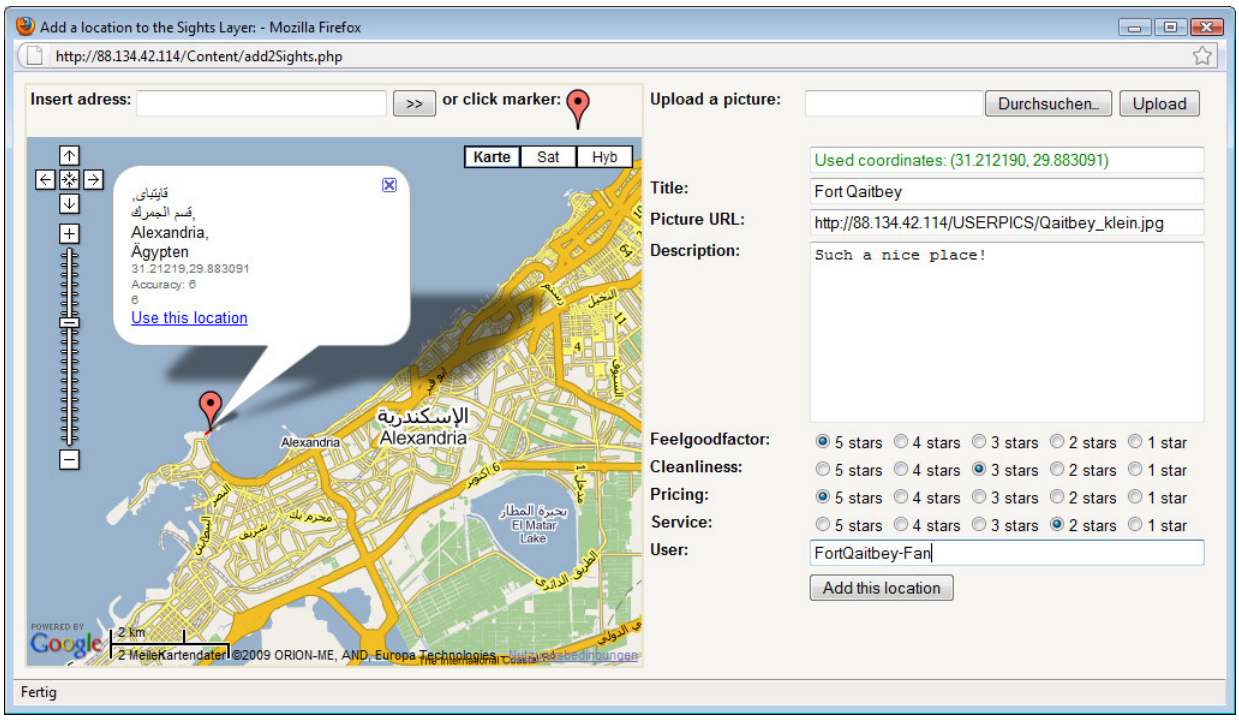

Abb. 6: Auf der AlexInfoMap können eigene POIs gesetzt und direkt bewertet werden

Abb. 7: Darstellung von Alexplore auf Smartphones, links mit Mobile-PlugIn – rechts ohne

Ein zusätzlicher Layer “außer der Reihe” ist der “Feelgood”-Layer. Er soll Ortsfremden einen Anhaltspunkt bieten, wo “man hingehen kann” und wo besser nicht. Touristen die den Stadtteil bereits besucht haben können hier Angaben dazu machen wie sich sich dort gefühlt haben und wieso. Hier ist nun der Punkt, an dem das gezielte Sammeln die größte Überschneidung mit der Raumplanung besitzt. Durch geschickte Auswahlmöglichkeiten können dem Besucher hier Aussagen entlockt werden, an die er so sonst wohl nicht gedacht hätte. Geben nun zum Beispiel viele Besucher an, es gäbe zu wenige Querungsmöglichkeiten an der Straße, kann entsprechend reagiert werden. Die Probleme zu kennen ist der erste Weg sie zu lösen!

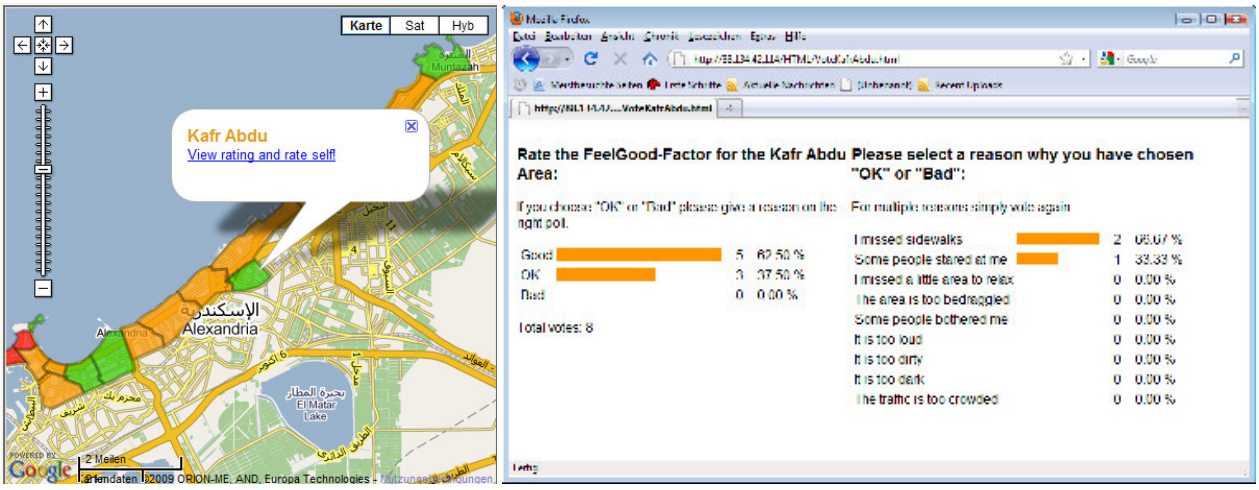

Abb. 8: Im Feelgood-Layer werden städtische Komponenten direkt bewertet

Je nach städtischer Problematik kann dieses Bewertungstool (und natürlich auch alle anderen) angepasst werden. Das Beispiel Alexandria zeigt, dass es auf viele verschiedene Arten möglich ist, gezielt Informationen zu erhalten – ohne wie bislang aufwendige Erhebungen durchzuführen. Selbstverständlich ist hier nicht „alles Gold, was glänzt“, zweifelsohne wirft das Konzept zahlreiche Probleme auf. Dennoch zeigt es die Möglichkeiten, die wir als Planer bereits heute besitzen. Es zeigt durch dass durch die Sammlung verschiedener Instrumente (Worpress, GoogleMaps, MicroPolls, etc.) und durch den Aufbau einer Community (dies entspricht im weitesten Sinne der „Sammlung von Menschen“) ein Pool an raumplanerisch interessanter Informationen angelegt werden kann. [PICH, 2009]

4 CONCLUSION

Die beiden Beispiele zeigen auf sehr unterschiedliche Weise zum einen wie gesammelt werden kann und zum anderen, was hierdurch möglich ist. In beiden Projekten wurde ein eigenes Geoinformationssystem aufgebaut. Während das Flächenmonitoring-System dem klassischen Planungungsalltag entspringt, ist Alexplore als ein Experiment zu sehen, dass die Grenzen des Sammelns austesten sollte. Neben der Sammlung von Geodaten und möglicher Software wurden für Alexplore auch die Anwender „gesammelt“. Beide Ansätze, haben zweifelsohne ihre Daseinsberechtigung – es ist allerdings unbedingt notwendig sie hinsichtlich ihrer Intention zu unterscheiden. Passives Sammeln wird immer nur dort Sinn machen, wo ohnehin Bürger eingebunden werden sollten bzw. sich dieses zur Information anderer Bürger anbietet (z.B. im Sinne von Bewertungstools). Damit hätte dies beispielsweise für den Aufbau eines Flächenmonitoring-Systems keinen Sinn ergeben. Hier geht es darum zielgerichtet Daten zusammenzustellen – der Nutzer dieser Datensammlung ist meist auch der Ersteller. Bei Alexplore ist der Planer ebenfalls der Nutzer – jedoch steht er gleichberechtigt neben dem Bürger bzw. im Falle von Alexplore dem Touristen. Es geht hierbei um eine win-win-Situation. Der Planer erstellt die Infrastruktur zur Sammlung und bietet damit dem Touristen etwas. Dieser wiederum „revanchiert“ sich, indem er dem Planer Daten generiert, die dieser für seine Planungen verwenden kann. Hiervon profitiert letztenendlich auch der Bürger bzw. Tourist, denn durch eine bessere Planung, werden unsere Städte lebenswerter. Das Flächenmonitoring-System kennt diese Art von Kreislauf nicht. Hier erarbeitet sich der Planer eine Datengrundlage, die er -auch- als Bürgerservice zur Verfügung stellt. Daher ist eine Kombination der beiden Ansätze auch nur bedingt möglich. Im Falle des Flächenmonitoring-Systems ist eine genaue und zuverlässige Datengrundlage zwingend notwendig. Diese lässt sich allerdings nur mit dem nötigen Fachwissen erstellen, daher kann der Bürger die Gemeinde maximal auf mögliche Flächen aufmerksam machen, wodurch allerdings die „Datenfindung“ der Gemeinde beschleunigt werden kann. Eine ähnliche Situation bietet sich bei dem Beispiel Alexplore, hierbei wird insbesondere auf Aktualität und Subjektivität der Daten Wert gelegt. Da diese möglichst umfangreich bzw. breit gefächert seien sollen, ist das Hinzufügen von Daten seitens des Anbieters nur eingeschränkt sinnvoll.

Bei all den Potenzialen und Vorzügen, die das Sammeln bietet, dürfen Planer jedoch auch nie vergessen, dass sie neben dieser Verantwortung noch eine weitere besitzen: Sich zu fragen wo die Grenze all dessen ist! Dies bezieht sich sowohl auf die Bereitstellung von Daten (Stichwort: Datenschutz) aber auch auf deren

Generierung. Denn wenn die Daten nicht vom Planer selbst erhoben werden, besteht immer das Risiko, dass diese falsch sind.

Werden die Grenzen jedoch eingehalten, können alle Sammlungen der Planer gemeinsam die Städte von morgen nachhaltig gestalten – in diesem Punkt unterscheiden sie sich also doch vom Eichhörnchen!

1 ABSTRACT

This paper outlines the development of public participation 2.0 user types based on the existing Web 2.0 user types. The theoretical concepts were tested on nexthamburg.de, a public participatory platform enabling the users to exchange the ideas about the future of the city Hamburg. Existing Web 2.0 user typologies classify users according to their activity and according to their communication with Web 2.0. We adapt these user types for the needs of public participation and test them on our study case with nexthamburg.de. We classified users according to their interaction into passive, active and reactive users. The underlying functions of the website, on which the study is based, are the posting of ideas, commenting on ideas and voting for ideas. This article presents the results of the first study phase, based on the quantitative data gathered with the help of eTracker and the website's database. eTracker is a software that tracks the behaviour of the users and their interaction with the platform. We aim at getting on overview of how people interact with a public participation platform and to classify the interaction forms and the user types in order to better understand the possible uses of public participatory platforms.

2 INTRODUCTION

The use of multimedia technologies facilitates new forms of integrating citizens into urban planning. The implementation of multimedia and interactive functions has the potential to introduce innovative forms of participation based on Web 2.0 technologies. With the integration of this concept, public participation becomes public participation 2.0 (PP 2.0) "using the new media to reach out to wherever citizens are active, including cyberspace" (Sommer and Cullen 2009: 2). Public participation 2.0 describes the usage of Web 2.0 technology for the purpose of public participation. Both concepts, Web 2.0 and PP 2.0, encourage and enable citizens /users to produce content, an idea, or even a network on the internet.

Providing content and instruments for public participation 2.0 necessitates the need to know who the users are, and how they interact with web-content and with each other. These two questions are of interest to us. On the basis of our research on interaction with a public participation platform we aim at developing innovative methods of presenting web-content for the purpose of public participation to foster an "active participation" and a high level of interaction. "Active participation" has a high position on the ladder of participation, introduced by many researchers such as Arnstein (1971) and Kingston (2007), and includes two-way participation and involvement in the decision-making process.

Our work introduces the development of a user typology for the case study nexthamburg.de. Nexthamburg is a public online think tank for the Hamburg of Tomorrow. On the basis of online postings, nexthamburg.de develops visions, strategies and concrete ideas about contemporary issues of concern by citizens in Hamburg, Germany. Everybody is welcome to post an idea; and every idea or vision that appeals to the other users, who have the option to vote for a contribution, has a chance to be applied in a study and possibly implemented.

For our study of the user typology of public participation 2.0 users, three variables for classification are of interest: interaction (passive, reactive and interactive), level of communication (peer-to-peer, intra-community, public) and spatial reference, which indicates if the idea applies to a specific geographical location or if it concerns the area of Hamburg in general. In the first phase of the study we concentrated on the interaction of the users with the selected public participatory platform. The level of communication and spatial reference are the focus of the second phase of our study, not presented in this article. Having data about their interaction would be of enormous advantage to understand user behaviour and thus to tailor applications to the users' needs. To know about users' needs and to react to them aligns with the objective to integrate more citizens into planning processes.

The main contribution of this article is in the analysis of the public participation 2.0 user types. We describe the process of developing a user typology of public participation 2.0. The underlying hypothesis is that by

knowing how the users interact with the platform, we can tailor the web content and interaction to their needs and their interaction with the PP 2.0 platform. Sharp et al. (2007: 11) states "Designers need to know many different things about users, technologies, and interactions between them in order to create effective user experiences. At the very least, they need to understand how people act and react to events and how they communicate and interact with each other."

The article is organised as follows. We present the previous work on web users in general, on different forms of interaction, and on developing Web 2.0 users' typologies. Section 3 gives a brief overview of the public participatory platform nexthamburg.de selected for our case study. Section 4 presents our research methodology and first results. We conclude the article with a discussion about the results and our future work.

3 PREVIOUS WORK ON WEB USERS AND USER TYPOLOGIES

3.1 Understanding the Web Users

There are many interpretations of the term 'user'; some even include the stakeholders in the user group (Sharp et al. 2007). The most applicable definition for our study is "people who interact directly with the product to achieve a task" (Sharp et al 2007: 430). We are interested in the users of public participatory applications offered on the Web 2.0.

There is broad consensus that web applications have to be tailored to users. Plenty of literature and approaches elaborate on this and how a website should look like and function (Tidwell 2006, Nielsen and Loranger 2008, Raskin 2001, Shneiderman and Plaisant 2005). These books offer a good view into interface- and interaction design and describe general guidelines. They propagate user studies, especially for sites with specific content. Questions that can be raised to get a broader picture of the user are: Who are the users of the system: experts, lay-men, men, women, what age, which ethnicity, etc.? What language and words do they use to describe what they are doing on the website? What do they want to achieve? What are the general tasks of the users? User studies vary with every specific application because some questions may be answered using general guidelines, but other specific problems need additional research and studies.

Most often the user specifications that influence the development of applications concentrate on the physical abilities, physical workplaces, diverse cognitive and perceptual abilities, personality differences, cultural and international diversity, disabilities and age (Schneiderman and Plaisant 2005). Some applications are only developed for und used by a certain group of people who have similar user specifications. Similar user specifications can also describe an interest that is shared, or the same goal that users want to achieve. Examples for webpages that have users with similar specification are websites that present information to a specific topic e.g extreme mountainbiking in the Alps, landscape photography or online maps like google maps that are used by users that have the goal to find a place. These websites are designed to follow the users' goal. For example, the application "google maps" is simple, it offers the user an easy search capability. The goal that a user, whatever age or personality, wants to accomplish, with the help of this application, is to find the selected place.

To find a common denominator on a low level of interaction and a simple design is on the one hand an option, but on the other hand it bears the risk of offering content that is insufficiently challenging and uninteresting for some users. This is especially a concern as applications for PP 2.0 have the potential to deliver a lot more than the information about a route or a place. To design attractive applications we suggest analysing web users according to their interaction with an application instead of describing them with pre-defined age classes or the level of education, as some user typologies do. This article is our first study of users topologies based on the users' behaviour and their interaction with the participatory application based on the Web 2.0 technology.

3.2 Interaction and Interaction Design

In the most general terms, interactivity simply describes an active relationship between two things (Salen and Zimmernann 2007: 58). It comes in many forms. For the purpose of designing interactivity it is important to understand what forms of interactivity the designers create. Interactive design is, according to Shedroff (2000: 269), "at once an ancient art and a new technology" because media "have always affected the telling of stories and the creation of experiences". Even passive experiences such as reading or watching a video can

be understood as interactive, because they "involve an interaction between the mind and the device or the imagination and the story" (Shedroff 2000: 283). Salen and Zimmermann (2007: 59) describe "cognitive interactivity" and "beyond-the-object interactivity" as two of four modes of interactivity. While the first describes the psychological, emotional interaction with a system, the second describes the participation within the culture of the system, e.g. the fan culture of a game. According to Salen and Zimmermann (2007: 59), the explicit interactivity referes to the interactivity mode which enables reciprocal interactivity; the user manipulates the application and the application responses. This mode of interactivity is especially of interest to us and our study presented in this article. The fourth mode of interaction according to Salen and Zimmernann is "functional interactivity" (2007: 59). This mode describes the "functional, structural interaction with the material components of the system" and thus refers rather to the interface than the manipulation of an application (Salen and Zimmernann 2007: 59).

Different approaches of interactivity vary according to the specific activity of the user. Interaction with an application starts with looking at the interface and operating the system, e.g. typing the address of a website or choosing it from the bookmarks. Sharp et al. (2007: 64) substantiates different interaction types by distinguishing four types: Instructing, users issue instruction to a system; Conversing, users have a dialog with a system; Manipulating, users interact with objects like holding, opening or placing; and Exploring, users move through a virtual environment or physical space.

Basic interaction design starts with analysing the needs and requirements of the users (Sharp et al. 2007). However, the users are not always capable of describing their desires related to an application. This is because they are often not aware of what is technically possible. Suzanne Robertson terms these the "undreamed-of requirements" (Sharp et al. 2007: 432). These requirements can be approached "by understanding the characteristics and capabilities of the users, what they are trying to achieve, how they achieve it currently, and whether they would achieve their goals more effectively and have a more enjoyable experience if they were supported differently" (Sharp et al. 2007: 432). Indentifying requirements should be partly done by the stakeholders, but they are not always aware of the users´ requirements and needs. This is one of the reasons why it is the definition of the requirements, to a large part, as the task of the interaction designers. Requirements can consist of a variety of different specifications such as look and feel requirements, usability requirements, operational requirement, etc. (Sharp et al. 2007: 526). In our study we concentrate on the explicit interactivity and observe in which way the users manipulate and use the existing online public participatory platform.

3.3 Online User Groups

In Germany, several studies of online users (Markt- und Medienforschungsinstitut Result 2007, ARD/ZDF Online Studie 1997-2009) try to describe the typologies of the Web 2.0 users. Their analyses focus basically on the users of the web-based platforms for market research. They suggest the distinction between the following two basic types of users: the users that participate actively by creating content and the users that participate passively by watching and reading content. Both groups contribute to the Web 2.0 in a mutual dependence. Passive users form an audience for the active users' inputs and contributions. According to the study "Typologie Web 2.0" (Markt- und Medienforschungsinstitut Result 2007) around 30 percent of the Web 2.0 users are respectively information- and entertainment seekers. The first group uses the internet to obtain information; they participate optionally by asking questions in e.g. forums to get more information. The second passive group consists of users that seek entertainment in form of e.g. games, music or videos.

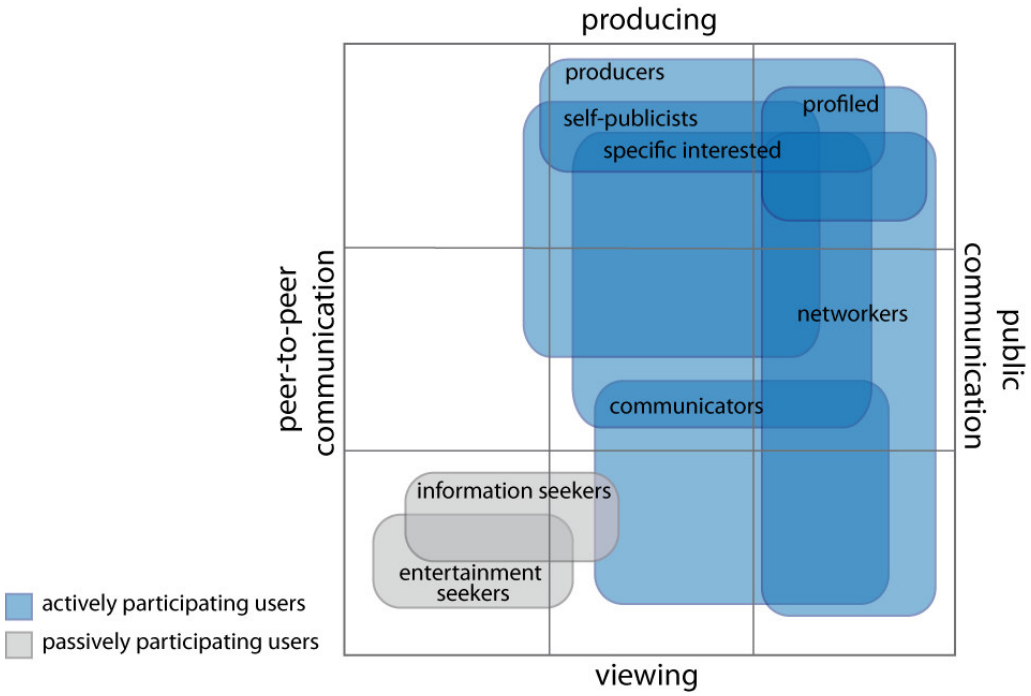

Fig. 1: Typology of Web 2.0 users (Markt- und Medienforschungsinstitut Result 2007: 37)

The group of the active users is more fragmented. Figure 1 shows the categorisations of the different users. The subgroups of the active users are developed on the basis of two axes: One axis for the level of creation; producing to viewing; and the other for the level of communication; from individual communication to public communication. The users are classified into groups according to the mode of their communication and the art of their interaction, beginning with just viewing on to producing content. The sub-groups are defined as: communicators, profiled, specific interested, networkers, producers and self-publicists. Communicators do not have a basic interest in creating content, they use Web 2.0 to communicate. The classical Web 2.0 user, in the study called “profiled”, uses all options to communicate and to create to the same extent. “Specific interested” use the Web 2.0 potential to communicate and to produce in the service of their interest. They are not as extroverted as the producers and self-publicists and can overlap with networkers. Networkers take advantage of the communicative aspects of Web 2.0, but they also create. Typical Networkers are the users of social-networking-sites. Producers are interested in publishing their photos, videos, music etc. Their focus is on showing their work, and the community and communication with other people are secondary. Self-publicists have the aim to present themselves by e.g. writing diaries on a weblog. They can overlap with the producers.

In this study, the basic goals of the users are added in order to be able to classify the users characteristic traits. The goals are, for example, to produce, socialize, or to present oneself. Without adding those traits self-publicists would show almost the same characteristics of action and thus the same position in the table as producers or networkers. However, because they follow different goals, their range of possible activities varies.

4 CASE STUDY NEXTHAMBURG

Our study case nexthamburg.de is a public think tank available on the Internet. Its main focus is the city of Hamburg and its future development. The citizens can post their comments and ideas directly through the online platform nexthamburg.de. Visions, strategies and concrete ideas are developed in a diologue between citizens and the nexthamburg team, on the basis of online postings by citizens. The posted ideas are about contemporary issues citizens in Hamburg are concerned with. Everybody is welcome to post an idea. Citizens can contribute by commenting on posted ideas or by voting for the ideas posted by other citizens. Every month three ideas that get the highest number of votes are appointed top ideas. These top ideas are featured in an extra area on the website. Every half year a session is organized where the voted top ideas are discussed and one final winner is selected. The sessions are organised as events where people interested in

future developments of the city can physically meet and discuss the issues. The winning top idea is further developed and analysed in a feasibility study.

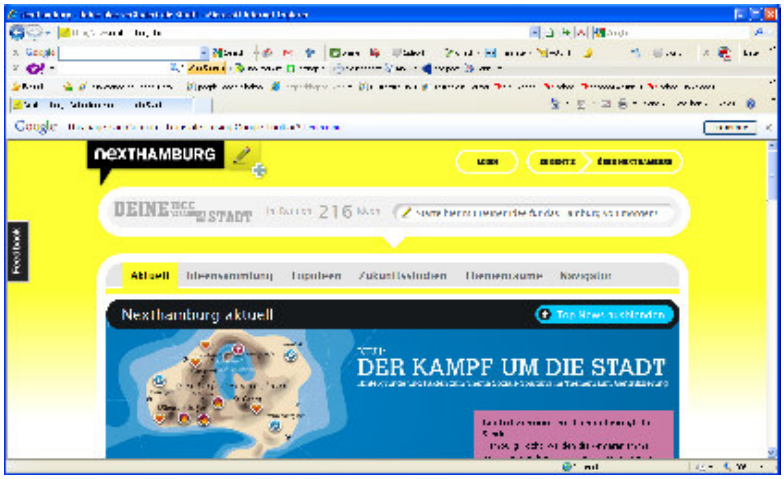

Fig. 2: Nexthamburg user interface (www.nexthamburg.de)

The philosophy of nexthamburg.de describes a bottom up process in public participation. Citizens can post every idea they have, even if it is not plannable at first sight. Nexthamburg does not promise that ideas will be put into practice, but offers a platform for discussions and exchanges among the citizens and planning experts.

During our study period from July 2009 until the end of January 2010, the first version of the platform was online. Citizens had the possibility to post their ideas about the planning issues in the city of Hamburg, comment on the posted ideas and vote for the best idea. The public participatory platform was available online to every potential user without login. This was changed with the second version of the application as of February 2010. During our study period, 78 ideas were posted that resulted in 213 comments for these ideas and 7265 votes. These three interaction forms are the focus of our study. The methodology and our first results are presented in the following section.

5 STUDY OF PP 2.0 WEB USER TYPES: AN EXAMPLE OF NEXTHAMBURG.DE

In our research we are interested in users typologies and their possible classifications. This study is focused on the analyses executed on the example of a Web 2.0 public participatory platform. The data available were gathered with the help of the software package eTracker, which tracks the users and their interaction with the system. The data is gathered in the form of simple statistics. For our study we combined it with data from the nexthamburg.de database, that gives information about postings, comments and votes. In this section we present our initial analysis of the user types on the example of nexthamburg.de.

5.1 User Types and their Levels of Communication

According to the data analysis, we identified the following three interaction types of users (table 1): active, reactive and passiv. Active users produce content, which means that they post ideas, vote and comment. Reactive users react on the existing content by voting or commenting, but do not produce any content themselves. Passive users visit the website and gather information presented on the nexthamburg.de platform.

For our further classification of the users and their interaction with the nexthamburg.de platform we used the characteristics of the user typologies based on the web user types 2.0 (Medienforschungsinstitut Result 2007). We distinguish among several levels of communication. Peer-to-peer communication refers to the communication among peers. Intra-community communication describes the communication within a community. For both kinds of communication a log-in is needed. Public communication, without log-in, is the communication which is visible for every visitor of nexthamburg.de. Based on these interaction types public participation user types such as the information seeker, the producer, the special interested or the networker can be identified on the nexthamburg.de platform.

Interaction types		Level of Communication
passive	Visiting the website without commenting, voting or posting	Peer-to-peer
active	Posting ideas	Intra-community
reactive	Commenting on ideas or voting	public

Table 1: Interaction types

Further parameters interesting for this study include the spatial and thematic reference of the users' postings; Specifically, postings that apply to a specific location or if it concerns the area of Hamburg in general and which theme it applies to. Some initial research in these two categories was done by Matern and Petrin (2010, forthcoming). We aim at extending our study with these parameters in the next stages of our research.

5.2 Data for the Analysis

The data concerning the interaction of the users with nexthamburg.de Web 2.0 public participatory application was gatherd with eTracker. eTracker is a software which enables real-time webanalytics based on pixel technology. By loading an invisible 'counter pixel' with every web-page, the number of page impressions can be retrieved. Additional information is gathered through interaction of the user with the website and stored in a database on the server. We used the data collected in the period from July 2009 to the end of January 2010 and combined statistics compiled from the software eTracker with data from the nexthamburg data base where the postings, comments and appendant information is saved. The data gathered in this way gave an overview about how many users visited the webpage nexthamburg.de in the test period, where they entered the website, how long did they stay, which browser they used, etc. The eTracker data was, due to the website technology that was used during the study period, not able to display information about the number of postings, comments and votes.

One of the interesting categories measured by eTracker was the "value unique visitors". This parameter counts the number of users in a specific time frame, usually 30 minutes. During this time the user is counted as one visitor no matter how often she leaves or visits the website. The value of unique visitors is only an approximation; more accurate data about users can be retrieved if they have to log in. The available data also includes the number of postings and comments per user and the number of votes per posting. These data gives ample information about the distribution of interaction. At this phase of our study no data about intra-community and peer-to-peer communication was available, as the website did not have a login area during the study period.

5.3 Results of the Analysis

With the help of the nexthamburg.de database we were able to reconstruct some basic types of interaction. In table 2 we show an overview about the overall number of interactions during the study period from July 2009 to the end of January 2010. Votings are, with 96,1%, the most attractive form of interaction. 2,8% of the users commented on the posted ideas, and only 1% of interactions are postings of ideas. A possible reason for this is the simplicity of voting. If you like an idea, you click on the "support" button and give your vote anonymously. It does not take much time. Posting an idea needs more involvement. First one needs a good idea and then she has to describe and post it publically on the platform. Although not many users post, the number of the average posting per user is quite high. The users that post, post in average 4,5 ideas. Users that comment, write in average 7,6 comments (table 3). These numbers indicate high involvement by the users that actively contribute. It indicates that once they are attracted by the platform, they tend to stay active a rather longer period of time.

Overall number of interactions (postings, votings, comments) during the study period		7556
Number of postings	78	1%
Number of comments	213	2,8%
Number of votes	7265	96,1%

Table. 2: Overall number of interactions (postings, votings, comments)

Postings/ comments per active user that has posted/ commented	
Average number of postings (per user that has posted)	4,5
Average number of comments (per user that has commented)	7,6

Table. 3: Postings/ comments per active user that has posted/ commented

During the study period we identified 100 users that interacted either by posting an idea, by commenting or by doing both (table 4). 60% of the users contributed only by commenting, 21% posted an idea and only 20% did both. This means that almost all users that posted an idea also commented on other ideas. 100 users interacted in an active, respectively, reactive way with the website. The remaining vistors tend to interact rather passively. The number of the remaining vistors can only be approximated (table 5). If we use the parameter "unique visitor" to get an overview about how many people have visited the website, only 1% of the users interact actively by posting and commenting. Data about votings were not available for single time users. Votes are only recoded per posting. Every 125 th user decided to post something on the platform, every 50th user commented, and every 1.25th user voted for the posted idea.

Number of users that interacted	100
Users that have posted an idea	21
User that commented an idea	59
Users that posted and commented	20

Table. 4: How users interact actively and reactively

Unique website visitors in the study period 02.07.2009-26.0.2009	9.028	
Average number of postings per unique vistor	0,009	Every 125th user
Average number of comments per unique visitor	0,02	Every 50th user
Average number of votes per unique visitor	0,80	Every 1.25th user

Table. 5: Unique website visitors

On the basis of these results it is almost impossible to build a reliable user typology for PP 2.0. Classes that could be built according to this data are the producer, which belongs to the group of active and reactive users, and the information seeker, which is the largest group and rather passiv. Producers are all users that create content in the form of posting or commenting, and information seekers are the remaining users that visit the website but do not contribute.

6 CONCLUSIONS

Knowing the users and their requirements is crucial for the developers of public participatory 2.0 applications. It is especially important to understand the functionalities the users use and the ways they interact with the system. The better an application serves the user´s interests and behaviour while they are online, the more motivated the citizens will be to participate. Knowing the requirements of the nexthamburg.de users, the designers of the platform would be able to tailor the platform to the users' needs and thus to serve the community by giving them the interaction styles they want and need to best communicate their ideas about the future of Hamburg. In doing so, the designers could be reactive to their needs.

In our study we analysed how the users interacted with the Web 2.0 participatory application in the period from July 2009 to the end of January 2010. We observed the following three parameters; postings, comments and votes. The aim was to define a user typology for public participation 2.0 users. In this phase of the research, we were only able to classify the users into active and reactive producers and passive information seekers. The majority of the users, 96%, voted. Voting followed by commenting with 2,8%, and postings with only 1% of all interactions. Obviously most users prefer to contribute in the less time consuming way, in this case by voting. Our study shows that the more involvement which is needed for an interaction, the less people would actually do it. Only 1% of the unique website visitors were active by posting or reactive by commenting and voting, the remaining users only read the content published on the website.

The results of our study give an overview about the usage of the three core-functions of the website. If we want to know more about "undreamed-of interaction styles and functions", we have to carry out additional interviews and gather some more data. Interviews are also needed in case we want to specify the public participation 2.0 user types. As long as we do not know what goals people have when they contribute on the public participatory platform, we cannot classify them into specific types of users. The only groups we were able to define at the moment are the producers and the information seekers. A possible classification into more detailed groups, such as specific interested, networker or communicator, requires additional research.

The new, second version of nexthamburg.de application has been online since the beginning of February 2010. It enables improved webanalytics due to its new concept. Every page is tracked separately, thus it is possible to know which page has been loaded and how often by the users. A login now is required for users that want to comment and vote for the presented ideas. These additional functionalities, which enable the gathering of additional data about the user´s behaviour, will enable the designers and researchers to gain better statistics about the users` behavior. With additional information about the way the users interact with the application, we will be able to classify the users into further groups, such as the networker, who communicates within the nexthamburg community, or the special interested, who cares for thematically related topics or for a specific geographical area. While data about the spatial and thematic reference is available and has not been examined for this study, data about the form of communication is only available since the launch of the second version of the website in February 2010. This data will enable us to continue our research on the Web 2.0 public participatory users and their typologies. In the next phase of our research we plan to analyse the new data related to the more specific information about the ways the users interact with the selected public participatory platform.

The analysis results concerning user interaction will be, among other things, the basis for our further research on interactive map-based applications for public participation. This research builds on our previous research in public participation in urban planning (Krek 2008; Wagner, Kulus and Krek 2008; Steinmann, Krek, and Blaschke 2004a and 2004b). Our vision is to overcome classical GIS functions like zoom, pan or layering. We aim at introducing an intelligent adaptable map that facilitates a high level of participation and communication, considering the way users interact with web-content. Studies about the users's interaction will be very helpful for the design of future interactive applications.

Development and environmental protection in the coastal urban area of the municipality of Glyfada (Greece)

Agisilaos Economou

(PhD National Technical University of Athens, Environmentalist, Address: Nikaias 18, 17122, Athens, Greece, email aghs@mail.ntua.gr)

1 ABSTRACT

Nowadays, the urban environment faces several management problems such as planning and sustainability. The various policies that are implemented to solve the above problems must be consistent not only with the EU directives but also to take account of existing urban and spatial plans for the area. Reconstruction of man-made environment and the construction of infrastructure such as roads, schools, gymnasiums, is one of the directions of European policy on urban environment. These interventions should have the least possible effects on the natural environment of the city in which they take place.

This paper studied the effects of the construction of a gymnasium in the coastal urban area of the Municipality of Glyfada in Attica, on the natural as well as on the human environment.

Initially the physiognomy of the area, is studied. Then, via an estimation of the environmental repercussions on the natural as well as the human environment, and after interviewing all the organizations involved, the evaluation of the repercussions on the natural environment is assessed. The research showed that the specific work contributes to strengthening the infrastructure of the urban environment, the enhancement of education and generally the enhancement of its development.

2 INTRODUCTION

The area of Glyfada is situated geographically in the southern part of the coastal area of Athens. It is surrounded by the mountains of Hymettus to the east and by the Saronic Gulf to the western (Fig.1).It is an urban area that was developed due to good environmental conditions and proximity to the previous airport of Greece.

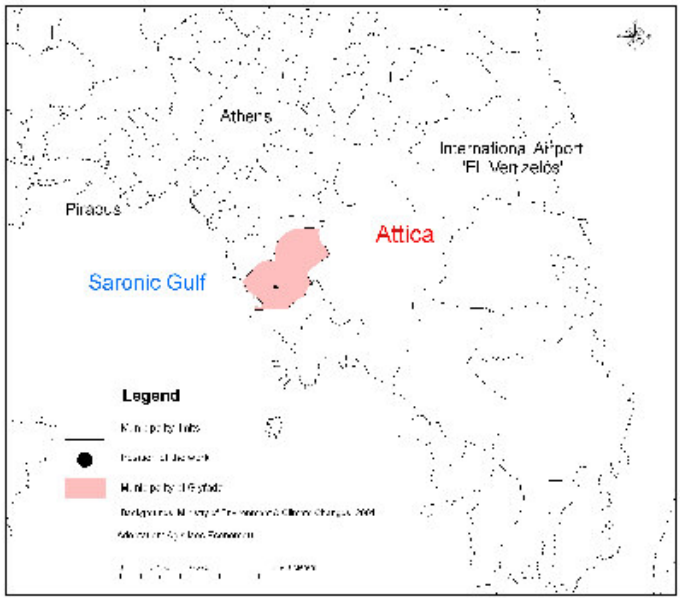

Fig.1. Research area

Regarding the development physiognomy of the municipality, the area of Glyfada has significant social, commercial, and sports facilities, modern school buildings and others.

The area of Glyfada is one of the best cases of permanent residence due to good weather conditions and the shopping centres which have been developed in the area. The area is a place for residents with high incomes.

In the Municipality of Glyfada a number of infrastructure works such as road works in order to improve the public transport an d development of the area and to serve the 2004 Olympic Games have been constructed.

This work refers to the construction of a gym and a building for cultural events near the 6th high school of Glyfada. These are designed to provide students with the opportunity for sports activities, entertainment and education in the form of cultural events that will take place during the year.

3 REGENERATION WORK

The regeneration works in the area of Glyfada are works which increase the standard quality of life. Such works are the road works, schools units, sports facilities - Gym, open space works, pedestrian roads, and others. Specifically in the area of Glyfada the regenaration works are (fig.2):

- Road works - Transport: The tram lines connect the coastal area of Glyfada with the northern border area of Glyfada as well as with the urban centre of Athens. The two major roads Poseidon and Vouliagmenis Avenues have connected the area with the rest of Attica area, as well as with the Piraeus Port and the Airport of Spata. The existing port mainly serves private tourist and fishing boats.
- School Infrastructure: In Glyfada there are 48 schools (17 nursery school, 17 primary schools and 14 high schools) in which there are 14 other co-housed schools. Totally, the school units have a potential of 8322 students. (ERC, 2007).
- Sporting facilities - Gym: In the area there are 5 Gyms and 25 athletic organizations which cover a large number of sporting activities (Sports Agency Municipality of Glyfada, 2008). In addition, 12 projects of the Sports Organization of the Municipality of Glyfada as tennis, volleyball, wrestling, athletics, basketball and others are taking place in this area with 2130 participants.
- Green (open areas) – pedestrian streets: In the area of the Municipality there are green zones and open area.

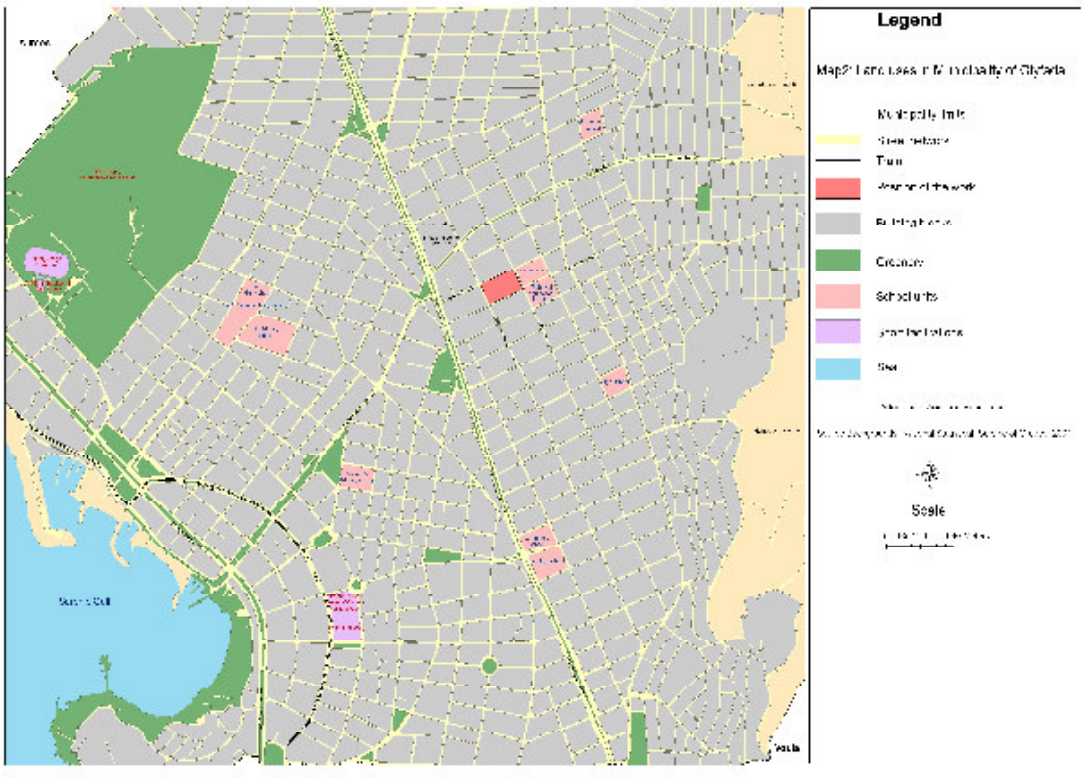

Fig. 2. Land uses in the Municipality of Glyfada

4 FACTORS THAT INFLUENCE THE REGENERATION AREA

Land uses

Land uses are an important factor for the further upgrading of the area. The main human activities in the area are:

- Commercial companies (Retail and Wholesale, the shopping centre of Glyfada is one of the biggest in south of Attica) and recreation and supra-local radiation
- Consultancy services (banks, business offices)
- A few scattered workshops and craftshops
- Hotels Units

Environmental problems

Flooding phenomena in the coastal roads that cause difficulties in traffic. The concentration of large quantities of rainwater is due to many factors such as: the rainwater collection is partial and does not cover the whole area of the Municipality of Glyfada, also there are great differences in height and the ground is rocky resulting in the reduction of soil absorption (Economou, 2008).

- Increased traffic in the centre of Glyfada and lack of parking spaces.
- Degradation of the beach of Glyfada due to the construction of the marina.
- Degradation of the urban environment due to increased building. By 1970, the text law for grating has contributed in the increase of the building area. In the area of Glyfada, the building factor is 0.8.
- Air pollution of carbon dioxide due to car traffic.
- Noise pollution due to vehicle traffic. The areas next to major roads face the biggest problem.

Development planning – Growth development – Policies

Other important factors for the development of the area are the development plans as well as spatial and urban plans which determine land use and the level of intervention with regenerations works.

Also, the economic growth gives the local authorities the possibility for more effectively interventions works in area.

Furthermore, various policies affect to a small or to a large degree the development of the area and therefore the regeneration works and upgrades.

The case of the construction of the gym and building for cultural events as a means of regeneration and upgrading of the area.

The gym includes: A gym, a basketball and volleyball court with 300 seats. The total area of the building is: E = 1390 m2 (724 m2 sports area, 263 m2 rows - about 300 spectator seats and 403 m2 of utility space).

Cultural events area: The space for cultural events including the exhibition hall - library by with PC spaces, exercise room - ballet, rhythmic gymnastics, aerobics room and exercise machines. The total area of the building with main and auxiliary areas is: E. = 1887 m.2

Surrounding area: In the surrounding area a basketball and a volleyball fields are to be constructed. Also, a part of the existing trees will be maintained, while new trees will be planted near the construction area.

5 RESEARCH

The research showed that:

The choice of the location the closed gym was made on the basis that site chosen shows the following advantages.

- The existence of the 6th high school next to the plot, has reinforced the choice of this location due to the possibility of providing students with an area for sports activities.
- The plot where the work will take place belongs to the SBO.SA, and has been characterised as school area by the No. 18036/360/05 decision of the Prefecture of Athens (Official Journal of the Hellenic Republic, 2006)
- Lastly, the position has access to the existing PPC network for electricity, water supply network

The proposed work is included in the total planning of the School Buildings Organization to strengthen school infrastructure with gyms and cultural events space. Also, the proposed location of the work has a goal

to acilitate the movement of high school students to sports facilities and to give motives for the development of sports activities during the school year independently of weather conditions.

Promote the cultural education of students of the area via cultural events (exhibitions, dances, and others) that will take place in the cultural centre. To act as a magnet for students for cultural education, entertainment and sports activities.

6 PROBLEMS DURING THE PERIOD CONSTRUCTION OF WORKS

According to personal interviews with local authorities and School Building Organization officials, in the area of Glyfada there was a strong reaction from residents who were in direct contact with the area. They have the opinion that these works will degrade the environment via the introduction of sports activities and the reduction of green areas.

This reaction was in contrast to the decisions of local authorities and the School building Organization for the upgrading school buildings, the management and promotion of the area.

Similar reactions existed in the construction of the gym in the school area of the Municipality of Pefki resulting in postponing the works.

According to the School Buildings Organization similar facilities have been constructed in many area of the country with no such reactions. In a country level during the period 2004-2007 7 class of multi-purpose uses and 27 gyms are being built with a total budget of 48,537,050.00 euros. Nowadays 3 multi-purpose halls and 11 gyms are under construction with a total budget of 22,713,730.00 euros (http://www.osk.gr).

In the case of the construction of the Indoor Sports Center in Glyfada, the above mentioned reactions were overcome after the adoption of environmental conditions from the Environment Directorate of the Prefecture of Athens. Thus, the construction of the work has started.

In addition, according to the Presidential Decree (Official Journal of the Hellenic Republic, 1987) such operations in urban areas which are in accordance with directive of the European Union for upgrading the standard of living of residents area authorized (Commission of the European Communities, 2006).

Studies – Environmental repercussions

A number of studies such as, architectural design, hydraulic, fire protection design, structural design, environmental study and others took place for the construction of these works.

According to the environmental assessment, the proposed work will not cause negatives effects to the surrounding area. Particularly the repercussion are (Economou, 2008):

During the work's construction period: During the period of construction the repercussion will be minimized at least due to measures. These measures concern: Safety of workers on site, reducing noise and dust production, protection of the residents from work activities and the movement of vehicles and machinery, and finally prevention measures for the collection and disposal of waste in appropriate areas.

Repercussions on the Anthropogenic environment: Taking measures in accordance with workers safety and protection legislation as well as the compliance with environmental procedures minimize the effects on the human environment. Also, with the appropriate configuration of the area (new plantings), there will be a positive influence on the students of neighbouring schools and the residents.

Repercussions on the Natural Environment: Compliance with the environmental conditions both for the management of liquid and solid waste reduces the environmental effects both during work construction and during the operation of the work. Consequently, the limits and measures for the management of solid waste, air emissions from industrial boilers which are used to heat buildings and noise limits during the operation of planting are followed. The liquid waste is disposed in the central waste pipe of the City and the solid waste collected by garbage trucks of Glyfada. Also, the uprooting and replanting of existing trees in another area of the municipality, contributes to the enhancement of vegetation.

7 CONCLUTIONS

According to the above it can be seen that the area of Glyfada is faced with environmental problems from the existing activities. A way to face these problems and to upgraded this area is through regeneration works. As has been shown above, the construction of a gym and a cultural events building as well as the regenerations

of the surrounding area will contribute to the development of sports activities and cultural education of students in the area.

Also, these works will not have negatives effects on the environment, due to the respect of environmental conditions while the regeneration of the environment will enhance the area. Consequently, these works can be considered in total as regeneration works which will enhance and elevate the area.

However, totally, the improvement of the quality of residents can not rely solely on such interventions. As I underlined above, a set of interventions is needed in the area such as high quality services, measures to protect the environment, green areas, and others so that the area may continue to provide high quality environment for the residents.

Finally, we should emphasize that the current practices for the construction of infrastructure works, require the active participation and consent of citizens. This is because in many cases there is apparently a delay or permanent cancellation of works, due to the reaction of the residents. We must move from the model of "authoritarian government" to the model, of “participatory governance” at a local level.

1 ABSTRACT

Major transitional changes can be recognized in Serbia in last ten years affecting all main sectors of society. Serbian firm political destination toward EU integration puts enormous challenges to the government reform processes due to comprehensive legislative and regulation harmonization. Even thaw many of new laws and national strategies have been adopted, their implementation is very hard and slow. Very specific challenges are faced in field of planning and governing sustainable urban development. Sustainability as a concept is introduced in everyday life of Serbia rather recently, with major delay comparing to the other European countries. In spite the fact the in academic circles sustainability was over twenty years the subject of planning approach redefinition argue, first important policy and regulatory documents ware adopted last year. Now major problems are faced in planning practice due to very low level of understanding and knowledge about methods and techniques necessary to achieve sustainable solutions. The situation is even harder when planning practice is additionally challenged with the local political priorities that are generated from philosophy opposite from sustainable. Therefore, now Serbia is the challenged to find creative ways to speed up the planning and governance practice transition towards contemporary European sustainability concepts and in the same time meeting the current economic development needs. In past five years several international support programs ware implemented, aimed to build municipal capacities for integrated strategic planning and governance using different ICT solutions. Experience of six Serbian municipalities where concept of Territorial Information Systems - TIS was introduced and implemented trough pilot projects showed that it could be used as an instrument of planning approach transition supporting methods and techniques that foster integrated development and sustainable community solutions. This paper will give the review how two years implementation of six pilot TIS projects affected and improved planning and governance practice in Serbian municipalities introducing different new instruments and methods. The potential of TIS as a bottom up instrument for planning and governance improvement was recognized and fostered by National Strategy of Spatial Development adopted few months ago.

2 PLANNING TRANSITION IN SERBIA

2.1 Planning context

In this chapter we will try to outline some key points of current planning position in municipalities of Serbia aiming to provide the base for understanding why we tried to use concept of TIS as an instrument to foster planning approach transition toward integrated sustainable development.

„Sustainability got to Serbia recently, and with significant delay in comparison to other European counties. In spite the fact that we use the term for almost the two decades, we recently approached to develop some of the key documents regarding sustainable development or country sustainable status assessment. This situation is a result of insufficient knowledge and understanding of issues of sustainability, adoption or consideration of other priorities while the "transition" on sustainable development is delayed, insufficiency of economic resources for sustainable solutions, and very often due to negation of sustainability as an "sustainable" development philosophy." (Bajic Brkovic, 2009)

2.1.1 Transitional blind forces and abandonment of planning

General overview of urban and spatial development trends in last two decades gives us the picture of much more negative than positive issues. Urbanization process turned out to be more informal than planed and controlled. That is a consequence of overall Serbian society transition process, absence of adequate and clear policies of urban and spatial development and incompatibility of current planning model with the socio-economic changes. Planning system, previously established in socialistic society, is unable to follow changing processes initiated by fostered private sector at the begging of nineties. Since then in Serbian cities

encounter enormous illegal construction and contempt of valid plans, decrease of quality and quantity of public spaces and communal infrastructure, endangerment of ecological natural values in urban areas. Restructuring of economic forces, working zones and overall decrease in social services investment fostered population migration toward urban centers, which as a consequence brought enormous imbalances in territorial development.

Planning and management practice started to change in last ten years due to two main groups of factors: 1) inner: numerous requests of investors for more efficient administration of investment procedures, legalization, communal commissioning of suburban areas, establishment of land legal status public/private etc., 2) outside – international community pressure to establish more efficient mechanisms in regional and economic cooperation in field of industry, agriculture, transport, energy, etc., in environmental protection and ecological vulnerability monitoring, informal settlement and social housing, which quite differ from Serbian practice so far.

2.1.2 Back to planning? – Deregulation and planning purpose change

Fostered investment activities, after ten year of stagnation due to unstable political situation in Serbia, initiated inner factors of planning approach change. Local authorities started to reevaluate existing plans and initiated development of "new" urban and spatial plans that will more suitable meet the current needs. Under the private sector forceful pressure and need for fast legal administration of investments, municipal planning become very active and at same time limited to numerous small "one parcel" urban deigns or eventually communal general regulation plans. In most cases, direct implementation of general urban plans is enabled, due to their flexible reformulation and more stress to construction rules. In that way detailed regulatory plans, which ware one of that main planning instrument so far, are put aside and almost abandoned. Among the disciplinary discussion that was usually justified with nature of market conditions, construction demand dynamics, and therefore the disability of planners to plan "precisely" urban development. Step by step planning becomes a service of "investment urbanism", followed more and more often by very sharp public resemblance to "informal" planners-politicians-investors coalition.

It was clear that planning system started to transform, in spite the fact that legal planning regulatory framework didn't change, in direction of deregulation and problem oriented planning which was distinctive in liberal capitalism many decades ago. The purpose of planning is now interpreted as efficient administration of investment market and main infrastructure problems solving. In this sense, there is no substantial part of planning purpose such as urban development guided by fostered socialistic consensus on equality of rights on standardized living conditions, neither as urban development fostered by community collaborative visions of quality living.

„Construction process in Serbia is characterized with ad hoc decisions, absence of regulatory mechanisms, and unclear relation toward standards while the old ones ware rejected or mostly denied and new ones still don't exist or are not accepted, and where the construction rules and regulation of city space are defined primarily by investment interest, and secondly by public interest. The rejection of planning and planning mechanisms is noticeable, and advocating of "market" commonly interpreted as context with no regulatory mechanisms, no respect of public interest and state role. However, in development and construction of cities in every regulated state, role of planning, policies, strategies and regulatory mechanisms is substantial and conditio sine qua non for qualitative urban development." (Bajic Brkovic, 2009)

Marked based urban development was actual in western countries in second half of nineteenth century during the industrial revolution. Consequences of market based urban development ware so serious, especially in domain of environmental quality and social inclusion, which eventually lead to significant theoretical, conceptual and institutional change of western planning practice. From this point of view, the main question that has to be asked is whether Serbia will have to pass the whole development process from the initial stage of liberal capitalism, all together with the consequences of market based urban development, or it will find strength to consolidate their own knowledge and experience in comparison to other experiences aiming to define the planning system appropriate for the current situation and its own context?

2.1.3 Back to planning? – planning objective change and new planning instruments

Thanks to the previously mentioned "outside" factors of planning transition, i.e. more intensive international community inclusion in development processes in Serbia trough initiated process of stabilization and EU

integration of Western Balkan countries, planning and management practice started to change more significantly. In numerous of cities and municipalities of Serbia, in past ten years large number of international donor programs ware implemented, with aim to built national and local awareness, knowledge and institutional capacities in field of economy, rule of law, and also in all fields where negative influence of market driven urban development are expected, such as environmental protection, social inclusion of vulnerable groups, informal settlements sustainable solutions, civil society building capacities in a field of institutional organization and articulation of civil society participation in community development, cultural-historical heritage ambient and identity preservation and protection etc.

Therefore, under the influence of the international factors, except questioning of planning purpose, process of questioning of planning subject also started, along with process of knowledge propagation about new planning and management instruments. In last five years many municipalities in Serbia adopted different strategic plans: economic, sustainable, territorial, master plans for significant development projects, local ecological action plans, different social integration and inclusion programs, etc., which ware aimed to redirect planning objective from problem solving toward strategic collaboration, and planning concept from physical planning toward integrated sustainable territorial development. International initiatives created on a local level atmosphere of openness toward utilization of new methods and instruments of urban development. Nevertheless, this openness is first of all motivated by the local authority's recognition that there are the potentials for access to the EU pre-accession structural funds, while in the same time there is still no clear consciousness and knowledge what these methods and instruments are actual for, why we create them in collaborative way and how they should be implemented now.

2.1.4 Current planning challenges

In this moment Serbia is still faced with the situation with no clearly defined policies of urban and spatial development, in spite the fact that the general necessary social fundament is much more articulated in Serbian determination to access EU. Ratification of Stabilization and Association Agreement (SAA) between EU and Serbia, committed bought sides, among else, to establish tight collaboration to contribute to the development and growth of the Serbian potentials thus the economic relations will be in generally fostered, and policies and measures will be formulated in a way to enable sustainable economic and social development of Serbia, in the same time taking in the consideration the issues of environmental protection (article 88., SAA, 2008). One of the most significant obligations that Serbia accepted by this agreement is to harmonize with the EU law. In last five years political focus in Serbia was on social development in rule of law and economy.

According the European Commission report about Serbian progress for year 2008., Serbia made almost insignificant, i.e. insufficient move in a fields of environmental protection, information society services, statistics, personal information protection, human and physical capital, education and research, in which more significant changes are expected in following period. If Serbia succeeds to implement adopted National program for integration by the 2012., it should be technically prepared to take all responsibilities that are derived from EU membership.

Nevertheless, there is still the question of Serbian essential and operative preparedness to implement obligations and regulations in practice. Integrated territorial development and actual policies of territorial cohesion in EU, where urban and spatial development have very important role, are very complex processes in which Serbia will not be able to actively participate unless serious effort is put in preparation of resources and capacities for this step. In that sense, the main question is how and with what instruments is possible to redirect and foster Serbian planning "transition" from actual toward collaborative communicative approach under the modern, organized and competent good governance, which takes into account principles of sustainability defined by EU and global development policies?

2.2 Directing the planning transition

Even though, as we could see from previous chapter, key disciplinary questions considering planning concept in Serbia started to be considered over a decade, more consistent institutional, legislative, regulatory and practical changes are still missing. On one hand, this situation is a consequence of still unclear social and political directions, and therefore unclear political determination on urban development strategies which remained on the margins of current political focus (Bajic Brkovic, 2009), and on the other, it is a

consequence of overall insufficiency in knowledge about nature, objectives and role of planning in new social conditions which will be actual in the moment of Serbian accession to EU.

„In the current conditions when in Serbia inclusion in global flows of capital and privatization is expected, planners have to adjust their own professional services to the reality dynamics" (Lazarevic Bajec, 1996). Upcoming law harmonization with the EU in a field of environmental protection, information society services, statistics, education and research, will not automatically put Serbia in a position of functional easy inclusion in EU regional development process. Current policies of urban and spatial development in EU member states are harmonized with numerous EU strategic documents, such as: European Spatial Development Perspective from 1999., Lisbon Sustainable Development Strategy 2000., revised in 2006 . in Goteborg, EU Territorial Agenda from 2007., Green Document on Territorial Cohesion from 2008. , and much more documents which are forming context for EU member states definition of national urban and spatial planning concept. In that sense accession to EU implies substantial changes in a field of urban and spatial development, especially in policy making, institutional arrangements and development of new instruments, methods and techniques. Except law harmonization, Serbia will have to position itself politically and strategically in context of EU and according to that finally redefine planning concept and system.

Considering the current development condition and available resources in Serbia and actual urban development trends in comparison to the EU member states, Serbian planning system should be very flexible in usage of variety of instruments and methods in order to follow up and manage inner change dynamics and in the same time to provide the capacities for development of Cities strategic visions as a part of EU network. That means that role of planners must be significantly changed in relation to the one defined in traditional planning. Planners must be competent and capable to analyze and recognize development mechanisms, choose different adequate approaches, creatively crate and innovate process of planning and plans production, which cannot be any more limited to list of plans defined by current planning law.

These facts redirect the disciplinary consideration toward serious consideration of possibility to apply institutional model of planning in Serbia. „Institutional approach starts from the structure and action of different actors in urban development, reveals their interests and activities and places them in wider context of structural process. On the contrary from systems theory which produces idealized models of choice which are often divided from real interests, the ways how certain social processes produce events are considered. We are interested in structural tendencies which shape social process and in those above directly observable phenomena, such as for example heterogeneity of social groups, power misbalance among them and economic process within which groups are constituted and resources divided among them. Main question within this approach is how planners, which are employees of the state, collaborate with the representatives of social and economic groups in society. Knowing the socio-economic position of these representatives is very significant for understanding the scope of the influence that planner could have on their actions." (Lazarevic Bajec, 1996).

The role of planner conceptualized in this way, especially of those which are employed in authorities, demands high awareness, very complex knowledge and skills. Knowledge is referred to quality information about administrative territorial phenomena and changes, inner and considering wider context, about subjects of change, their institutional position and power, socio-cultural specificities, preferences and interest, activities etc. Skills are referred to ability to use different methods, techniques and tools for fostering communication and collaboration of all development actors.

Accordingly, when we ask question how and with what are the instruments to foster planning "transition" in Serbia in order to be prepared for involvement into EU integrated territorial development policies, than certainly one of the answers can be find in intense knowledge and information capacity building of all development actors. The fact that SAA, among else, is focused on collaboration in a field of education and research, information society services and statistic, underlines the significance that Europe give to concept of the knowledge based society.

3 CONCEPTUAL APPROACH TO TIS DEVELOPMENT IN MUNICIPALITIES OF SERBIA

The idea to use the TIS as an instrument to foster transition of planning approach in municipalities of Serbia turned out during the preparatory phase of project document of SIRP - Settlement and Integration of the

Refugees Programme, lately implemented by UN-HABITAT in the period of 2005. to 2008. . The Italian government decided in 2004. to finance the programme aimed to help policy makers and local communities in adopting workable and lasting solutions, while getting up a grip on the human settlements and urban issues. Some of the main activities of this programme ware: - improving, in most of the Municipalities, the skills to elaborate plans for local development, - developing, in six Municipalities, Pilot projects on Territorial Information systems, and - establishing a regional network for the exchange of experiences and lessons learnt. (Ramirez, 2008) That was the base for the conceptual development of the idea to use TIS in order to make more comprehensive and substantial influence on municipal planning approach. In following chapters the short overview of the key issues of this process, an also of achieved results will be given.

3.1 Concept of building up the awareness about new planning approaches by using TIS

Second SIRP component –Municipal component, was capacity building component and it was designed to enable six selected Municipalities to improve their effectiveness in their functions of governance and implementation of more complex development projects. The capacity building interventions set up methodology for the delivery of the technical assistance and to provide the necessary support to the other programme components. Each programme component interacted with others, i.e. housing one, profited from capacity building and the support to the integration of its beneficiaries. Integration between components activities was a leading principle in the project management cycle. Aside from integration, other important key words and concepts of SIRP methodology ware: participation, enabling, confrontation, partnerships, didactic approach, bottom up, learning with others, knowledge spread, information flow, “acquiring skills, instruments and tools”, “exposure to EU good practises”, “key actors of the EU integration process”. (Ramirez, 2008)

“The challenge of decentralisation, transition and integration in Europe might imply looking at the European Union framework (policies and methodologies(, in which local governments not only contribute to the economic and social development of their territory but, due to their closer position to citizens, are often appointed to implement the EU legislation. In transition countries, Local Authorities are more and more becoming protagonist in the decentralization process and their role in promoting central reforms might be crucial. Local Authorities can be champions of change, taking up the role of transforming their territories being trainers /locomotive of development, from bottom to up. SIRP has experienced that applying the “bottom up“ approach can really make the difference.” (Ramirez, 2008)

During the preparatory phase of the SIRP project document, group of the national consultants altogether with major international support from Italian and other international partners, according the assessment of Serbian contextual resources came up with a conceptual principles that are to be followed during Pilot projects implementation.

3.1.1 Achieving integration

The integrated approach to territory (understood here as the scenario in which all actors play and actions take place), comprises different and important meanings when related to \local development: functional integration, which means providing unitary implementation and management of actions related to different sectoral aspects; financial integration (i.e. public, private funding); integration of actors and policies, which means that subjects, competencies and policies are coordinated towards a common strategy; horizontal integration of players actions, sectors and resources thus producing grater creativity and inventiveness; vertical integration of all levels of governance and planning : from community level and their action plans, trough municipal, district, regional and up to the central level with national development plans and policies. (Ramirez, 2008)

The implementation of the integrated approach to local development, as conceived throughout SIRP Programme, started with the integration of information necessary for effective and efficient decision making processes. Achieving the integration of information is a complex process because it implies not only integration of different, often incoherent, data bases, but also the integration of information activities between governmental, public and other non-governmental or private institutions and organizations, as well as integration of knowledge and technology resources that enable such integration.

In order to ensure that decisions in the process for local development are based increasingly on sound and integrated territorial information, it is necessary to develop a system that will improve data collection and

use, the methods of data assessment and analysis, the availability of information and the production of information usable for decision-making. Therefore, it was use the concept of TIS and experiences of good practices of the Italian partners. (Lalovic, 2008)

Concept of Territorial Information Systems –TIS is a new generation of decision support systems based on GIS technologies developed with aim to support integrated territorial sustainable development. Due to it openness to the all development actors, it represents also new planning and governance instrument. TIS concept comprises its scalable implementation from municipal up to the regional or national level and it is spatially correspondent to the territorial administrative division. It is structured in a way that first of all supports activities coordination and organization of different local institutions, public enterprises, non-governmental organizations, private sector in the process of planning and governance of integrated development. Therefore, it integrates data and information not only about the available resources but also on all activities that put them into function: economic, environmental, social, technological etc. (Lalovic, 2008,1)

The concept of Territorial Information System enables and supports integration in many ways:

- As a tool that provides efficient collection, storing, updating, sharing, publishing of data and information, enabling the integration of information activities among different local governmental and non-governmental institutions and organizations.
- As a tool that allows effective processing, analysis and displaying of all forms of territorially referenced data and information in order to produce accurate, appropriate, fast and integrated information on territorial resources: environment, society and economy. In that way it enables integration of scientific and expert activities, supports knowledge and technology exchange.
- As an instrument to support decision making processes in planning and management the development of the territory by providing integrated complex quality territorial information that reflect various interests and give the possibility of qualitative assessment of decision alternatives to all decision makers, increasing accessibility for all citizens to local development processes and supporting the implementation of the local community integrated development activities.

Territorial information systems are an instrument that initiates and foments integration of a very important part of local community life: knowledge and awareness of its territory and ongoing development processes. One of the main conceptual assumptions of TIS is also that it is developed as a tool which will provide wider territorial integration. For example, if TIS is developed in two neighbouring local communities following common basic rules and norms, it will provide integration of information activities between two local authorities enabling recognition of common interest and supporting development partnerships. In that way territorial “borders” divisions vanish. The assumption that all local communities have developed their local TIS provides the ground base for development of regional and national TIS. Data and information, which are in details collected and processed on a local level, can be integrated and processed to provide valuable information necessary to manage regional development and certify national development policies. Vertical information integration should be enabled by the established laws, normative and regulatory frameworks which define the common ground for data and technology sharing form local to national territorial levels.

3.1.2 Building up the awareness - information flow, knowledge spread, learning with others

A TI is structured in a way that should provide complex information derived from integrated package of very different data on natural and built environment, socio-economic resources and activities. It this way TIS integrates the information on community life and gives the base for rising the awareness of the citizens about specific details on available community resources, ongoing processes, about participating actors and the results of the actions taken. (Thomas, Humenik-Sappington, 2008) Integrated information on community life enables TIS to be an instrument of quality information production and therefore to support collective decision making. In this way, by activating the abilities of community to exchange knowledge and learn together, TIS stimulates integration of community activities and provides quality base for mutual communication and collaboration in decision making about local development. (O’Looney, 2003)

TIS should also support the community integration on higher territorial level, such as regional, by activating its ability to efficiently and effectively exchange knowledge and experience with partner communities. GIS technologies placed in a fundament of TIS, are providing the ability to join several local TIS in one and to

connect it vertically with higher territorial authorities. This ability of integration is not important only because the intention of vertical coordination but also to enable better territorial marketing or protection of the specific resources that several local authorities share. (Lalovic, 2010.)

3.1.3 Raising the public accessibility to local development processes

Functionalities of TIS are conceptualized in a way that supports public accessibility to local development process in a different ways. Firstly, concept of TIS implies the production of different kind of informative materials (e- publishing, interactive services, printed reports, books and brochures etc.), adjusted to different public needs, that enable public access to local development programs, policies, plans, projects and activities. Special potential of TIS is the ability to map and visually follow the impact of this documents or decision taken on across the community territory on the web in every moment. The main objective is to inform wide public on ongoing activities, and to enable citizens to involve more actively in the community development process.

Secondly, since concept compromises that TIS relies on different sources of data (public, private, civil society) in order to integrate different values in decision making process, it enables that all community groups have accessibility to public portal to express their own stands, opinions and needs on specific development issues.

Thirdly, since usage of TIS provides possibility to produce malty criteria reports and maps understandable and acceptable to all, it enables stakeholders' accessibility to decision making process in more effective way. Therefore, through its conceptual methodology of data acquisition, processing, reporting and dissemination of generated quality information, TIS is supporting local governance to develop its enabling competency.

3.1.4 Supporting the participation process

If we want to make certain decision, it is necessary to understand: what choice we have, what we all want, - what are benefits of our wishes, - what we will lose if we choose one or the other solution. So, in order to support decision making process TIS has to enable not only the overview of the territorial resources and the processes of changing during the past, but also to enable to "look" at the territory through the eyes of stakeholders and to evaluate the possibilities through their own value system or through the system of community shared values. In practice, this requires very often very hard, time and money consuming participatory process, especially in cases dealing with issues of high public interest and importance. (Healy 1997., Innes, 1994)

In these cases TIS can support participatory planning process by provision of complex but understandable and custom tailored information about community life, enabling the citizens to widen the knowledge of ongoing processes in community, raising the awareness of changes in the environment in development processes before they get to discussion arena. (O'Looney, 2003) It is very important that TIS, since collects and integrates data and information from all society levels, enables the stakeholders to built up the information base for specific decision making process in a way that they think is proper and necessary. In that case TIS becomes an instrument to build up the mutual trust and prepares the base for communicative action. In that sense TIS provides a possibility to increase efficiency of the participatory process. The community groups that are to be involved in participatory process can be with the support of TIS efficiently prepared for the collaborative process. (Greene, 2000)

Next, during the participatory collaborative process of alternative scenario definition, TIS with its abilities to process, analyze and simulate different territorial situations, can support generating the alternatives to decide upon. At the end, it has high operative and analytical potentials for establishment of malty criteria evaluation mechanism which will later on be used as a monitoring tool.

4 EXPERINCES OF TIS PILOT PROJECTS IN SERBIAN MUNICIPLAITIES

"TIS are instruments to support planning, managing and monitoring the territory, where "territory", as applied in European practice and conceived by SIRP, goes beyond its spatial connotations and it is understood to be comprised of all its spatial elements, all actors which constitute its communities, its socio-economic and cultural values, and the actions and dynamics that shape its form. The integrated approach to territorial development is thus intrinsic to its own definition, implying both vertical and horizontal integration trough coordinated planning of resources and the use of the territory."(Galassi, 2008)

Experiences from EU counties show the application of TIS to various fields and segment of planning. When considering the public administration and its governance functions, this translates into developing and improving the efficiency and effectiveness of a series of user-oriented services, enhancing the communication and information flow within the local administration itself and its segments, as well as cooperation within community and with state administration, enchasing services to the citizens and business and enabling their participation in decision making processes, trough 1) the development and strengthening of capacities of an organized system of qualified experts and administrators, 2) the definition, rationalization and standardization of administrative procedures and 3) development of data services and appropriate technological infrastructures in order to provide access to data and information to execute administrative process. (Galassi, Lalovic, 2008)

4.1 TIS Pilot projects – key structural issues

Territorial Information System, by its structural complexity, is the system of highly qualified persons skilled in the use of ICT technologies, all forms of territorial data records, and the sets of activities for collecting, storing, updating, processing the data and information in a given institution and organization, supported by the process of elaboration of appropriate and efficient technology-aided tools. The main elements of TIS structure are:

- Territorial data and data base: usability and quality of data and information to form the knowledge base about the territory is achieved by its organization and integration in a Data Base. In real life, numerous records, data and information are collected on different administrative authority levels and within public and other organizations. Experience so far points out that a lot of records and data currently gathered on a local level can't provide high enough qualitative information to support good participative decisions. This means that sources of data and information have to be expanded to a wide range of new alternative sources (field surveys, "non-official" sources from civil society and public sector).
- Human resources: essential elements for developing, managing and using the TIS, carrying out activities for its conceptualization, organization and performance. The engagement of human resources can be structured according to the following roles: developers (urban planners, civil engineers, public administrators or managers), administrators (skilled IT technicians) and users (politicians, managers, entrepreneurs, businessman, unemployed, citizens, even children).
- Information and Communication Technology (ICT): TIS technological element is structured as a combination of hardware, software and ICT supported services. This combination can vary in each specific TIS case and depends on very different factors. The main one being the existing IC Technology level on local level, financial resources and institutional and human capacities to implement high quality ICT solutions. GIS technology is a very important part of TIS. GIS tools allow capturing, storing, analyzing and managing data and associated attributes which are spatially referenced to the earth, and to create interactive queries, analyze spatial information, and present the results of all these operations on thematic territorial maps. However, there will be data that cannot be processed in this way but still be part of TIS and processed by some other software tools.

In order for TIS to function, systematic relations between its key elements should be established and agreed upon:

- Modelling the TIS – integration of people and data: it is a complex process of choosing, structuring and integrating appropriate data on territorial resources in function of local communities' needs to decide upon something. In order to support group decisions in local development processes, data and information are needed, which will give us the best possible picture of the problem in the context that we have to address. The process of modelling the TIS, implies much more than simple collection and integration of existing data records. It implies the necessity of deep understanding of stakeholders needs and preferences. In order to model the TIS, a wide range of local community stakeholders should be engaged to select the specific data and meet their information needs. Only in this way data integrated in TIS can be processed and transformed in quality information for different users.
- Administering the TIS – integration of data and technology: it includes activities on coordinated TIS database development, maintenance and publishing, providing integration of information activities in

the local community. Contemporary solutions of TIS administration are centrally coordinated data sharing of distributed TIS data bases. That means that different local sectoral databases within different institutions and organizations, "owners" of specific set of data and entitled to collect, process and store them and having the responsibility to maintain the database and provide accurate and up to date information, are being shared and used by all community institutions and accessible to the public. In order to accomplish that, a TIS administration and management unit has to be established. The unit is usually placed within the local authority. It is entitled to establish and motivate inter-organizational data sharing and set up usability mechanisms through the establishment of data sharing and integration protocols, standards for data formats, standards for common ICT platform and metadata services. The administration and management of TIS at the local level can be set up in different ways according to the information, human and ICT capacities that the local community has. However, TIS administration should be also organized in a way that provides data and information that fit into norms and regulations that are usually set up on a higher territorial level (regional or national). This provides integration of information activities not only horizontally on local level but also vertically form local to national.

- Developing capacities for the TIS – integration of ICT and human knowledge: different TIS training programs should support the development of the necessary know-how to ensure sustainability of TIS and its proper efficient and effective development and usage. Since TIS by its definition means a permanent process of information services development, it should be matched with capacity building programs for different target groups organized by the unit entitled for TIS management and administration. Trainings should be tailored for different groups of people according to their role (public users, stakeholders, professionals, administrators) and usually scaled from basic trainings, which should provide common understanding on TIS basic concepts, raise awareness of benefits that TIS brings to the community and ways to use it, to advanced trainings, which should provide more sophisticated knowledge and skills necessary for further development of TIS information services. (Lalovic, 2008)

4.2 TIS Pilot projects – applied methodology

The methodology applied in Serbian Municipalities is based on a "step by step" approach, starting from thematic TIS Pilot projects, on an identified specific topic, specifically focusing on issues relevant to the development of the local context and as identified by any of local strategic documents and policies, in order to initiate the TIS and start up the ground for future upgrading and integration. Municipalities identified the implementation of Municipal TIS as an important tool to inform decisions and monitor development strategies and projects.

In each Municipality a Coordination body was formed, constituting from political and management representatives of the institutions and organizations related to pilot project topic. Their function was to support the development of the TIS project, to initialize and facilitate institutional collaborations for the implementation, evaluation and the assessment of achieved results. Technical working groups have been appointed by Coordination Body, comprised of members from different sectors, in order to ensure an integrated approach to setting up and developing the TIS.

Municipal working groups of experts and technicians have been following an iterative and incremental process for the development and further upgrading of the municipal TIS. The implementation process has been tailor made for each municipality and comprises several cycles of similar activities: - Designing and programming – conceptual definition and modeling of the database and identification of users' needs, - Implementation, acquiring and processing the data and integrating the data records, - evaluation and dissemination of the results. Each of tree cycles, have been carried out for each step and allowed the testing and upgrading of specific implemented technical solutions, quality appraisals of results. The final results of each TIS Pilot project have been published in Atlas booklets, on interactive DVDs, containing the geo-database accessible for consultations trough interactive maps and specific query investigations and some of then on the web which. (Galassi, Lalovic, 2008)

4.3 TIS Pilot projects – short rewiew

4.3.1 TIS for municipal land management in Valjevo

The Pilot Project was identified in order to address a series of problems the Public Administration of Valjevo was facing in managing municipal land properties and initiating the process of development of its territory. The development of an integrated information system was identified as a vehicle to upgrade the municipality's capacities to attract new investments and thus increase employment opportunities, especially for the poor and vulnerable groups of citizens.

Main problem to be addresses was the inefficiency and ineffectiveness in responding to the demands of potential investors since the Municipality could not provide public access, prompt and adequate information about possibilities of activating construction land. It happened that the same transaction over a real estate took place twice because of the lack of available and integrated information on performed procedures. Different administrative disintegrated systems of identification of lots in the land cadastre and ownership books make it hard to determine lots. Decision-making based on small number of correct data can be more reliable than decision making based on wrong data. In this context, the purpose of Pilot Project was mainly rising awareness of managers and other stakeholders in the local community about advantages and importance of using TIS.

The main goals of the Pilot Project are thus to support decision-making processes for management of municipal land at different levels and for different stakeholders; to integrate data from the cadastre and municipal land records in one integrated system oriented towards different users' needs; to provide access to diverse information on municipal land (current and planned conditions and land use, and infrastructure equipment) through the production of different interactive thematic maps and textual reports, and possibilities of multi-criteria search; to monitor effectively and efficiently the changes in the territory.

The TIS Pilot project in Valjevo has been realized by integrating different types and sources of data. In order to improve the quality of information to stakeholders in the area of management and development of municipal land, spatial data (digital orto-photo and land model, digitalized master plan and spatial plan, street network in digital format, cadastral maps) and alphanumerical data (land records) from various sources have been integrated. Data sources that have been used are: the Municipality of Valjevo, Cadastre–RGZ SKN Valjevo, Republic Statistical Office, Public Enterprise Directorate for town planning, construction land, roads and construction of Valjevo.

„Our vision for the development of TIS in the municipality implies the implementation of a distributed network of databases of municipal institutions integrated in a unique TIS. Therefore, further steps, based on existing TIS pilot project results, would be the following: presentation of TIS pilot project results to the public, local self government and experts with the aim to obtain the support for further development of TIS; expansion of inter-institutional co-operation by enhancement of already existing co-operation between Municipal administration, Public Enterprise Directorate for town planning, roads and construction, as well as by inclusion of other institutions that would have benefit from TIS; upgrading and further integration of the Pilot TIS through mapping of all planning documents, as well as integration of additional data related to public lighting, spatial and alpha-numeric (socio-economic) data.", was stand of Valjevo TIS team at the end of project implementation.

4.3.2 TIS Pilot Project to support tourism development – „The Best of Čačak"

In line with the adopted City of Čačak Development Strategy and the action plans on tourism and ICT, the implemented TIS Pilot Project aims at (1) initiating the development of TIS in the municipality as an instrument to support strategic decisions, implementation and monitoring of different plans in the field of tourism development, (2) raising awareness about the advantages of using TIS in everyday work of the Public Administration, as well as (3) promoting touristic resources and potentials of the territory.

Specific objectives of the project ware to initiate an integrated database of tourism resources and potentialities, and to ensure accessibility, integration and quality of data and information through the use of GIS technology, and the elaboration of different interactive analytic and thematic maps.

The Pilot Project integrated spatial and alpha-numeric data from different sources: Public Enterprise Gradac, Tourist Organization, Autoprevoz Čačak, Hiking Association Kablar, MGI Beograd, Geokarta Beograd. The

data have been collected, archived and integrated in a geo-data base providing integral information about touristic resources in the municipality of Čačak.

Different users of the municipal TIS have been identified: - Citizens and tourists interested mainly in tourist resources and activities in Čačak municipality. The interactive tourist map published, is intended primarily for promoting and informing tourists on Čačak tourist offer. The TIS publications illustrate the diversity of information that an integrated information system can offer to them; - Municipal decision makers, public servants, experts, the private sector, and citizens interested in the analytical part of Čačak tourist TIS. This modern information tool enables territorial analysis, when sectoral resources necessary for tourism development are in question. It is possible to access complex information on Čačak tourist zones, evaluate the degree of their development and identify strategic directions for potential improvements. Decision makers and municipal officers can obtain complete access to information by consulting the interactive TIS geo-database, and which is being permanently updated and kept in the municipal IT department.

The Development of information services and co-ordination of information activities in the Municipality of Čačak have been particularly intensive in the last few years. The municipal administration invested major efforts and significant resources in technological modernization of the IT department and this way it set up the conditions for development of modern tools to support management of territorial development. The activities on integration and harmonization of municipal databases have started. From that point of view, the TIS pilot project ”The best of Čačak” is one of very important projects because it introduces technological and organizational innovations to information services of the municipality – introduction of GIS technologies in the process of integration of municipal data, establishment of new procedures of intensive inter-institutional co-operation and strengthening the capacities of municipal officers.

“We truly hope that this project will contribute to the further development of tourism in our municipality, that the number of tourists, who find in Čačak and its vicinities their oasis of pleasure and leisure, will increase significantly and that the visibility of touristic potentials through the maps of this project will contribute to raising awareness on the significance of investments in tourism. The first next step in further upgrading and integration of our municipal TIS is to initiate the next pilot project in support to the management of economic resources and potentials of the municipality, as well as creating a digital address system on town and municipality level, and integration of additional spatial (first of all planning) and alpha-numeric (socio-economic) data.”, was stand of Čačak TIS team at the end of project implementation.

4.3.3 TIS to support rural development – „The ID card of rural villages„

The City of Nis recognized the need to improve the quality of information about rural areas to inform and support plans and actions for their future development. Therefore, the City decided to develop TIS to support rural development aiming towards information accessibility to various users and integration of data from different sources to achieve quality. The focus of TIS Pilot was the Municipality of Pantelej due to the fact some previous field research was done, through the Project “ID of villages”, and acquired data on different topics relevant to rural development. Furthermore, it was decided to improve database and additional alphanumeric as well as spatial data ware captured.

TIS office was established within the Municipality of Pantelej and equipped with hardware and software. During the period of development of TIS Pilot data from the following sources ware integrated: Municipality of Pantelej, PC Urban planning Agency, Clinical Centre Nis, Institute for cultural heritage and monuments protection, Serbian Orthodox Church, PC for Environment Protection, National Statistical Office.

In the final phase 18 interactive maps and reports ware published that cover four aspects of rural territory: - Ownership structure – maps that give information on the size and type of the ownership of the farms, - Economic structure – different queries on the type, size, income of economic production on the farms. - Social structure – maps and reports with data on number, density, marital status, income, profession of the inhabitants, -Natural and built environment – different integral information with data on areas covered by forests, mountains, agricultural land, built areas with services, agricultural facilities.

A project for further upgrading and unification of the city Information System has been formulated within the City of Nis Development Strategy, adopted in 2008, under the Operative Axis 4 on Governance: strengthening vertical and horizontal governance and participation of citizens and stakeholders, implementing an efficient system for planning, formulation of policies, monitoring and evaluation.

4.3.4 TIS Pilot Project on Touristic Resources in Kraljevo

Main purpose of the TIS we developed is to provide an integrated database on tourism in Kraljevo. The conceptual model of TIS database was oriented to its different potential users: tourists, experts, entrepreneurs, decision makers and we tried to integrate as much data as it was possible in one year period. During the different phases of the project implementation great emphasis was put on collecting relevant data. Most of the data was collected during field visits, although already existing data was used as well. The institutions that provided data are: PC Directorate Kraljevo, VGI Belgrade, Republic Geodetic Institute, Touristic Organization Kraljevo, Museum of Kraljevo, Municipality of Kraljevo, PTT and Telenor, Public Enterprise Serbia Railways, Kayak organization.

As a result of integration of various sources of data, spatial queries and interactive thematic maps on promotion and development of touristic resources and potentialities in Kraljevoware created: - Touristic map of Kraljevo, -Level and type of touristic potentialities in Kraljevo, -Analytical maps on traffic network and transportation, natural resources, services, demography, -Touristic potentialities and planning documentation.

TIS was institutionalized through the establishment of TIS working group as part of the Project Center, established in 2007., within the Municipality. The Project Center is active in raising awareness and motivating different stakeholders in the municipality to provide support and involve them in the overall process of development and improvement of TIS in Kraljevo. On this metter the official collaboration with Technical university of Kraljevo was establised. Next steps for upgrading of the TIS ware in the field of development of industrial zones, support rural development and management of municipal land. Now TIS is used for decision making base for Kraljevo Development Strategy formulation.

4.3.5 TIS to manage the development of industrial zones in Kragujevac

The TIS Pilot Project in the city of Kragujevac is addressing management of the first phase development of working zone along the highway Kragujevac – Batočina. Intention was to explore and identify possibilities of providing quality information to support the process of urban investments and project management for different groups of users such as decision makers, public offices of the city administration, private sector investors and other stakeholders interested in specific site construction.

On order to achieve pilot project goals TIS working group made an effort to integrate as much data and information as possible, necessary for Kragujevac investment zones development, such as: Master Plan of the city of Kragujevac 2015, the city investment guide, cadastral maps, cadastral maps of service infrastructure network, orto-photo, street network, plans of detailed regulation, urban acts, geological map. Very close collaboration on data sharing and integration was developed between key local and national institutions and organizations: Public Enterprise Directorate for town planning, the city assembly, Cadastre Office, Republic institute for statistics, Geokarta Beograd.

Significant results ware reached by provision of different interactive maps, textual and numeric reports, graphs and diagrams which refer to resources and potentials of the working zone giving the data on each construction site (spatial, type, structure, land utilization, geologic characteristics, planned building capacities, infrastructures). The Pilot Project has been expanded with integration in the overall map of all other working and industrial zones on the territory of Kragujevac. In the near future, They we plan to develop TIS on city land management using the experiences and models developed by the City of Valjevo.

TIS to support management of municipal housing stock in Pančevo

The municipality of Pančevo decided to support the development of the TIS tool to support municipal social housing programs implementation defined within the housing strategy of Pančevo with two main goals: raise awareness of local authorities and get necessary political support for further development of Pančevo TIS, and increase efficiency and effectiveness in management of the municipal housing stock.

Two attempts to activate the TIS project and setting up its organizational structure have been carried out during the year 2007, which successfully concluded with the involvement of the municipal administration, the IT Department, the Public Enterprise municipal Housing Agency, and the Public Enterprise Directorate for planning and construction. Significant amount of time was spent for the organizational preparation of the TIS Pilot Project, resulting in a short timeframe to be dedicated to operative work. In spite of the starting

difficulties we succeeded to establish an operative TIS team, which succeeded to reach significant results in a five months.

The geodatabase for social housing apartments records has been modeled and integrated with numerous spatial and alpha-numeric records. The focus of the pilot project has been the social housing building in Strelište, newly constructed with the support of the SIRP Programme. Spatial data and maps (Plan of Detailed Regulation, service network cadastre map, etc.) were collected and processed by the Public enterprise Directorate for planning and construction, and alpha-numeric data were collected from the Public Enterprise Municipal Housing Agency, and then integrated in interactive maps. This experience highlighted the need for development and introduction of standards and protocols for data sharing among institutions, further application and upgrading of TIS to support the implementation of social housing strategy.

5 CONCLUSION

Together with the cities of Cacak, Kraljevo, Kragujevac, Nis and Valjevo, UN-HABITAT has received the First Prize at the 16 Serbian Salon of Urbanism for the realization of Municipal Territorial Information Systems Pilot Projects in the category of "Application of Information Technologies to Planning", which main theme was "Urban Challenges", presented to the wide public the recent achievements in the sphere of urban and spatial planning, as well as innovative approaches to local strategic planning for development.

However, experiences of Municipalities that started TIS development showed that there are many problems that have to face during the implementation.

First of all, there is a problem of insufficient political support especially in the conditions when this activity is not regulated by national regulations or law. Comparing to the EU context, more regulated framework is given by numerous EU and national documents and policies that regulate and foster development of information activities of authority institutions, in spite of the fact that some of the member states still didn't put larger effort in their development. Insufficiency of political support is tightly linked to low level of awareness and knowledge about what the benefits of TIS are, and what is its role in the process of planning and governing the sustainable development, even in the context of development driven by market forces, described before. Still, in cases that we performed this experiment it was possible to acquire necessary support due to numerous activities that included not only the meeting with Authority representatives but also organizing round tables, specific trainings for a wider range of authority employees. In this process it was very important the fact of the presence of international support since there is higher trust in international authority than in national. Later on in the process in the phases of publishing the TIS results in each cycle, we succeeded to initialize to redirect focus on some questions of sustainability and to initialize public discussion on this meters. Thanks to the power of visualization that TIS has, we achieved this.

Secondly, the current institutional and organizational procedures in Serbia are mostly in conflict with the ones brought with concept of TIS. Institutions are very closed in their administrative and business performance and resist to a new forms of collaboration due to their fear that they will lose the share of power in community relations if they give and share the information that they have. Old administrative procedures are made in a way that is often very unclear what data is collected by which institution and they also don't have any protocols that oblige them to exchange the data or to share them. So often, we have the experience that there are many redundant and incorrect administrative data records depending on the fact which administrative body we address. The problem is more complicated in the moment when we face the fact that some of the data is owned by national institutions, since there is no efficient communication between local and national government levels. During the process of TIS pilot project implementation we succeeded trough work in practice to develop the atmosphere of trust between participating organizations and to in some of the municipalities foster institutionalization on a local level of these relations by establishment of protocols of data exchange and publishing. At the end this quality is also recognized on a national level, and now we have TIS recognized as important instrument of development within the National Strategy of Spatial development of Republic of Serbia adopted last year.

Thirdly, not all municipalities have the human and ICT capacities to develop TIS, i.e. the basic resources available in differen municipalities vary a lot. Finally, there is not enough level of e/services available to the public and the level of public e-knowledge is still low. This issue is vary serious and needs very creative strategies to find appropriate financial solutions to support further building capacities processes in

municipalities due to the fact that because of the current economic situation public investment in this field are not the priority.

In order to overcome these constraints it is necessary to organize comprehensive educational activities on raisin the awareness and promoting the importance of TIS, building up the knowledge and disseminating the skills, aiming to: - acquire necessary political support on national and on local levels, - foster collaboration between authority and public institutions, nongovernmental organizations and private sector in sharing the data and information using contemporary ICT solutions, - built up local human capacities for TIS development, - foster regulatory and normative reform necessary for information activities organization and coordination, - building up the capacities of the wider public access to TIS, etc.

Experience of Serbian municipalities is that more efficient and effective way to implement TIS concept is step by step approach, because implementing starting up the idea from the stretch, also acquires consuming participatory and collaborative process followed by slow and time consuming process of attitude and values change of all actors involved. In order to initialize TIS development Pilot project topic must be agreed in participatory and collaborative way and through several criteria: - urgency of a problem that must to be meet, - knowledge and motivation of the people that are to be involved in process, - available technological and financial resources, - amount and quality of already available data which provides base of producing fast firs results. Also experience of applied methodology showed that incremental process of implementation through several cycles builds trust between participating actors and also trust in their own capabilities to perform the task. So during the process when first results are visible after short period of time, also foster necessary political support.

At the end the most important thing that we achieved during the process is the fact that communication and collaboration techniques that we delivered during the pilot TIS implementation created the atmosphere of trust between the institutions involved in certain topic or sector, so their role and importance was redefined and recognized in new way. Now in many municipalities recognized partners from TIS pilot projects are also included in planning activities. Also this experience is also started to be applied in other topics of TIS expansion.

A almost one year after the closure of SIRP project four of the municipalities continued very intensively to develop TIS: Cacak, Karljevo, Kargujevac and Nis, relaying on their own resources. In Valjevo and Pancevo due to unclear political conditions the activities continued but much less intense. Very important are also the activities of the municipalities in mutual collaboration and knowledge and experience exchanged since they worked on different topics. The collaboration is also expanded to other municipalities which started with applying the GIS technologies.

Ours, national team that followed this project, overall impression is very satisfying and a bit surprising. Firs, at the beginning of project we expected one of the municipalities to achieve expected results on mach more modest level, yet we succeeded to implement the whole scope of the project in all municipalities. Second, for us it was surprising that preparatory phase, collaboration in participatory way and education and training, took twice longer time than the practical implementation of the project. From the point of view of the academic education and research that we represent, we gained valuable experience that we already incorporated in our curriculum.

Die Aktivierende Stadtdiagnose – Vorstellung einer stadtpsychologischen Methode zur Förderung nachhaltiger Stadtentwicklungsprozesse

Cornelia Ehmayer

(Mag. Cornelia Ehmayer, Stadtpsychologische Praxis, Pressgasse 6/3 1040 Wien, praxis@stadtpsychologie.at)

1 KURZFASSUNG

Das stadtpsychologische Verfahren [Aktivierende Stadtdiagnose] bildet die Grundlage für nachhaltige Stadtentwicklungsprozesse, die eine repräsentative Beteiligung der Öffentlichkeit vorsehen. Die Menschen werden zur Teilnahme aktiviert, da sie ihre eigenen Themen, Sichtweisen und Anliegen einbringen können. Die besondere Stärke dieses Verfahrens liegt darin, jene zu erreichen, die üblicherweise an solchen Beteiligungsprozessen nicht teilnehmen. Im zweijährigen wissenschaftlichen Forschungsprojekt „Kulturlandschaftsforschung und Agenda 21“ wurde die gemeindepsychologische Methode ‘Community-Diagnosis’ von Prof. Francescato (FRANCESCATO, 2000), Uni Rom, mit einem interdisziplinären Forscherteam und 12 internationalen Experten/-innen wissenschaftlich weiterentwickelt und in sechs österreichischen Gemeinden erprobt. Die Teams haben sich in unterschiedlicher Ausprägung (immer mit einem stark umwelt- und gemeindepsychologischen Schwerpunkt) aus ausgebildeten Wissenschaftlern/-innen und Studierenden folgender Disziplinen zusammengesetzt: Psychologie, Soziologie, Philosophie, Landschaftsplanung, Umweltökonomie, Geografie, Biologie, Kulturtechnik & Wasserwirtschaft.

Zuvor wurde die Methode ‘Community-Diagnosis’ im Pilotprojekt ‘Lokale Agenda 21 Alsergrund’ angewandt. Aktuell kam die Methode im Jahr 2009 in einer burgenländischen Gemeinde zum Einsatz. „Die Stadt aus der Sicht ALLER Bewohnerinnen und Bewohner zu verstehen“ lautet der zentrale Ansatz. Es geht darum zu erfahren, was die Menschen über die Zukunft ihrer Stadt denken, was die Themen sind, die sie bewegen und mit wem sie sich darüber austauschen. Methodisch werden qualitative Einzel- und Gruppeninterviews mit Bewohnern/-innen und Entscheidungsträgern/-innen nach Grounded Theory (GLASER & STRAUSS, 1998; CHARMAZ, 2006) durchgeführt und durch Beobachtungsverfahren ergänzt (FLICK, 2007). Als Ergebnis wird eine repräsentative stadtpsychologische Diagnose erstellt, die besonders auf jene lokalen Besonderheiten hinweist, die für eine zukunftsfähige Stadt- oder Gemeindeentwicklung von Bedeutung sind. Ein wesentliches Element dabei ist die Darstellung all jener Gruppen, die in eine nachhaltige Entwicklung einzubeziehen sind. Diese Darstellung nennt sich ‚Kommunegramm’. Mit der [Aktivierenden Stadtdiagnose] erhalten Gemeinden und Städte eine fundierte Unterlage, auf deren Basis sie nachhaltige Stadtentwicklungsprozesse starten können. Einerseits wird die Bevölkerung durch die Befragung motiviert, an weiteren Gemeindeprozessen mitzuwirken. Zweitens können die Ergebnisse der Diagnose mehrere Jahre als Entscheidungsgrundlage für politische Strategien herangezogen werden. Drittens wird auf lokale Besonderheiten Rücksicht genommen. Diese Methode stellt somit eine Verknüpfung des gesellschaftspolitischen Modells der nachhaltigen Entwicklung mit umwelt- und gemeindepsychologischen Ansätzen, sowie Methoden der Organisationsentwicklung dar.

2 EINLEITUNG

Die [Aktivierende Stadtdiagnose], im folgenden ASD genannt, ist ein qualitativ ausgerichtetes, methodisch vielschichtiges, teilstandardisiertes Verfahren, das disziplinenübergreifend sozialwissenschaftliche und psychologische Elemente enthält. Mit der ASD können zukunftsfähige Potenziale einer Stadt ausfindig gemacht und die Stadt auf einen partizipativen Stadtentwicklungsprozess vorbereitet werden.

Zur Erstellung der ASD werden lokale Akteurinnen und Akteure umfassend in den Erhebungsprozess einbezogen. Entsprechend einem Grundsatz der Stadtpsychologie werden im Besonderen die Bewohnerinnen und Bewohner angeregt und ermutigt, sich zu beteiligen. Das in einer Stadt vorhandene Beteiligungspotenzial wird dadurch von Anfang an auf ein höheres Niveau gehoben und die Beteiligungskultur gestärkt. Nun betrifft der Beteiligungsprozess nicht nur die Bewohner und Bewohnerinnen einer Stadt, sondern natürlich auch die Stadtverantwortlichen. Der Nutzen und der Gewinn für die Entscheidungsträger aus der ASD finden sich nachfolgend angeführt.

2.1 Der Gewinn aus der ASD für die Stadtverantwortlichen

Die Verantwortlichen einer Stadt erhalten eine umfassende und detaillierte Analyse der Stadtwahrnehmung und des Verhältnisses der Bevölkerung zu ihrer Stadt.

Sofern das Vorhaben, einen nachhaltigen Weg einzuschlagen besteht, finden sich in der AS-Diagnose all jene Themen aufbereitet, die es diesbezüglich zu behandeln gilt.

Der Vorteil liegt dabei u. a. auch darin, zu erfahren, wie sich die Bevölkerung zu diesen Themen positioniert.

Neben den Stärken und Schwächen der Stadt werden auch die unbewussten Wahrnehmungs- und Denkmuster, die sich negativ auf die weitere Stadtentwicklung auswirken können, erkennbar.

Erschlossen wird ferner, bei welchen Bewohnerinnen- und Bewohnergruppen eine besonders hohe Bereitschaft zur Beteiligung vorhanden ist.

Die Erfahrung hat gezeigt, dass sich nicht zuletzt durch den von der ASD ausgelösten Stadtentwicklungsprozess die Kommunikation ganz allgemein und im Besonderen zwischen Politik und Bevölkerung verbessert. Die Menschen einer Stadt begrüßen es, wenn sie um ihre Meinung gefragt werden. Der Politik wiederum nützt es, um die Meinung der Bevölkerung fundiert Bescheid zu wissen. Insgesamt erhalten die politischen Verantwortlichen mittels ASD auch eine qualifizierte Grundlage für alle politischen Entscheidungen, bei denen die Haltung der Bevölkerung von besonderem Interesse ist.

Die ASD enthält zudem eine über die angeführten Punkte hinausgehende Vielzahl an Zwischen- und Nebennutzen. So löst bspw. nicht selten die Anwesenheit eines externen Forscher-/Forscherinnen- und Berater-/Beraterinnen-Teams den einen oder anderen Konflikt, der schon längere Zeit in einer Stadt schwelte und nicht gelöst werden konnte. Donata FRANCESCATO (2000) beschrieb den allgemeinen Nutzen einer Stadtdiagnose wie folgt: “The benefit a community has by hiring an outsider team, which does this kind of work is like to go to a doctor for diagnosis what our health is what the community’s health is … so it is a tool to plan your own future …” [Der Gewinn, den eine Gemeinde daraus zieht, dass sie ein Team von außerhalb engagiert, das diese Art von Arbeit verrichtet, ist vergleichbar mit dem Besuch bei einem Arzt. Dieser stellt die Diagnose über unsere Gesundheit, mit der Stadtdiagnose erhalten wir eine Diagnose über die Gesundheit der Gemeinde…sie ist also ein Werkzeug, um unsere Zukunft zu planen…]

2.2 Der Gewinn aus der ASD für die Stadtbevölkerung

Die Stadtbevölkerung erhält mit der Diagnose eine leicht fassbare und gut verständliche Rückmeldung darüber, welche und wie viele verschiedene Bevölkerungsgruppen in der Stadt vorhanden sind und in welchem Verhältnis diese sich zueinander befinden, wer in der Stadt „das Sagen“ hat und welche Stimmen ungehört bleiben - was den Bewohnern/-innen in der Regel nicht völlig unbekannt ist. Durch die ASD findet sich dieses Wissen jedoch in umfassender Form aufbereitet. Erst die Zugänglichmachung dieses Wissens ermöglicht den Bewohnerinnen und Bewohnern sich in der Folge zu positionieren, ihre Stellung in der Stadt aber auch zu hinterfragen. Für Bevölkerungsgruppen, die am Rand einer Stadt agieren, ist diese Form der Rückmeldung oft der erste Schritt, sich aus einer bspw. isolierten Position zu befreien.

Dazu ermutigt die Diagnose ebenfalls: Sich über die eigene Stadt Gedanken zu machen, um sich aktiv an einer Veränderung zu beteiligen. Die ASD birgt viele Potenziale in sich: Sie ist Analyse, Diagnose, Befund und Beratungsansatz in einem. Sie kann sich für eine Stadt und ihre Bewohner über viele Jahre als äußerst nützlich erweisen, sofern sich Bewohner und Verantwortliche ernsthaft und gemeinsam auf einen zukunftsfähigen Weg begeben (wollen).

3 ABLAUF EINER AKTIVIERENDEN STADTDIAGNOSE

Die ASD kann prinzipiell auf alle Gemeindeformen (Katastralgemeinde, Standardgemeinde, Marktgemeinde, Stadtgemeinde…) angewandt werden. Unterhalb einer Einwohnerzahl von 1000 Personen, empfehlen sich aus ökonomischer Perspektive modifizierte Varianten der Diagnose; nach oben hin sind betreffend Größe einer Stadt oder Gemeinde kaum Grenzen gesetzt. Auch Millionenstädte stellen kein Problem dar. Im Gegenteil, die ASD wurde von Anfang an (auch) für große Städte konzipiert.

Abhängig von der Größe der Stadt (nach Einwohnern und Fläche) sind sowohl Größe des Forscher-/-innen-Teams als auch Dauer der ASD. Als Richtwert kann gelten, dass das Forscher-/-innen-Team aus ca. acht

Personen besteht und eine ASD rund vier Monate dauert. Für die Arbeit in der jeweiligen Stadt wird ein interdisziplinäres Erhebungsteam zusammengestellt und eingehend vorbereitet.

ARBEITS-SCHRITT	ABLAUF/INHALT	
Schritt 1	**AUFTRAGSVERGABE**: Beschluss zur Durchführung einer [Aktivierenden Stadtdiagnose] durch die Gemeindevertretung	BEGLEITENDE ÖFFENTLICHKEITSARBEIT
Schritt 2	**ERSTINTERVIEW** mit dem Bürgermeister/der Bürgermeisterin	
Schritt 3	**DATENERHEBUNG** IN DER GEMEINDE: Erhebung von Primär- und Sekundärdaten mittels Triangulation, Komparativer Analyse und Theoretischem Sampling	
Schritt 4	**IST-ANALYSE:** Themenanalyse (Darstellung der zentralen Gemeindethemen) und Erstellung eines Kommunegramms	
Schritt 5	**DIAGNOSE** DER ZUKUNFTSPOTENZIALE: Herausforderungen auf dem Weg zu einer zukunftsfähigen Stadt	
Schritt 6	**REFLEXIONSGESPRÄCH:** Rückmeldung der Ergebnisse an BürgermeisterIn / Gemeindevorstand	
Schritt 7	**DISKUSSION DER ZUKUNFTSPOTENZIALE** mit der interessierten Bevölkerung	
Schritt 8	**BEFUND** (Dokumentation)	
Schritt 9	**ABSCHLUSS**: Übergabe der ASD (Befund) an BürgermeisterIn / Gemeindevorstand	

Abb. 1: Übersicht zu den neun Arbeitsschritten einer Aktivierenden Stadtdiagnose.

3.1.1 Schritt 1: Auftragsvergabe

Eine grundlegende Voraussetzung für die Durchführung der ASD ist eine politische Entscheidung. Dieser vorangestellt ist zunächst ein gemeinsamer politischer Wille, der im Beschluss mündet, eine ASD durchzuführen, um für die Herausforderungen der Zukunft (besser) gerüstet zu sein. Ein konsensualer Beschluss vonseiten der Gemeindevertretung ist dabei unbedingt anzustreben. Geht diesem ein ausführlicher inhaltlicher Diskussionsprozess voraus, erhöht es die Erfolgschancen der Diagnose, da davon ausgegangen werden kann, dass bei den politischen Entscheidungsträgern ein Problembewusstsein hinsichtlich anstehender Veränderungen der Gemeinde und ein damit einhergehender Wunsch nach Veränderung vorhanden ist. Üblicherweise nehmen der Bürgermeister oder die Bürgermeisterin (der Bezirksvorsteher oder die Bezirksvorsteherin) während der ganzen Verfahrensdauer eine zentrale Rolle bei der Durchführung der ASD ein. Sie sind am Beginn (bereits im Vorfeld eines Gemeinderatsbeschlusses) die ersten Ansprechpersonen, die über die Vorgehensweise, das Ziel und den Ablauf der Methode informiert werden und sie treffen die (Vor-) Entscheidungen, ob und wann eine ASD in ihrer Gemeinde durchgeführt wird. Schon bei den ersten Vorgesprächen informiere ich darüber, dass die politische Unterstützung über die gesamte AS-Diagnosephase für den Erfolg wesentlich ist. Die politische Unterstützung muss dabei über die gesamte AS-Diagnosezeit nach außen (für die Bevölkerung) und nach innen (für die Gemeindevertretung) sichtbar und spürbar sein. Dies ist wichtig und notwendig, wenn tragfähige nachhaltige Veränderungen bewirkt werden sollen. Zudem zeichnet die ASD ein sehr ehrliches Bild über die Gemeinde und liefert möglicherweise auch Ergebnisse, die den politischen Entscheidungsträgern nicht zu 100 Prozent gefallen. Gerade dann braucht es die politische Unterstützung von höchster Ebene, da ansonsten die Gefahr besteht, dass der begonnene AS-Diagnoseprozess ins Stocken gerät. Üblicherweise übernehmen der/die BürgermeisterIn oder der/die BezirksvorsteherIn in ihrer integrativen und überparteilichen Funktion die Rolle der Vertrauens- und Ansprechperson für den AS-Diagnoseprozess. (In Ausnahmefällen übernimmt ein Mitglied des Gemeindevorstands diese Aufgabe).

3.1.2 Schritt 2: Erstinterview mit dem Bürgermeister/der Bürgermeisterin und Auswertung

Das Ziel des ersten Interviews mit dem Bürgermeister/der Bürgermeisterin besteht darin, einen ersten Eindruck, ein erstes Bild von der Gemeinde zu gewinnen. Dieses erste Gemeindebild wird durch die darauf folgende Erhebung entweder bestätigt, modifiziert und nicht selten auf den Kopf gestellt.

Beim Erstinterview mit dem Bürgermeister/der Bürgermeisterin bin ich vorrangig an den aktuellen Themen der Gemeinde interessiert. Auch will ich wissen „wo" es der Gemeinde gut geht, „wo" aktuelle Probleme liegen und welche Lösungsansätze diesbezüglich vorhanden sind. Weiter führende Fragen zielen darauf ab, herauszufinden, wer (Einzelpersonen, Gruppen) das Gemeindegeschehen aktiv mitgestaltet und wem bzw. welchen Gruppen eine Außenseiterposition zugesprochen wird. Für die weitere Datenerhebung wichtig ist auch die Nennung sog. „Lokaler Akteure", d. s. Personen, Gruppen, Institutionen, die gemeinderelevante Funktionen innehaben. Auch muss für das weitere Verfahren eruiert werden, wo möglichst viele unterschiedliche Bewohnerinnen und Bewohner anzutreffen sind, um diese befragen zu können. Gegen Ende des Erstinterviews stelle ich (bewusst offen gehalten) stets die Frage nach der Zukunft der Stadt. Den Abschluss des Erstinterviews mit dem Bürgermeister oder der Bürgermeisterin bildet die Frage nach einsehbaren schriftlichen Unterlagen über die Gemeinde, wie beispielsweise der Stadtchronik.

Orientierungspunkte für die Gestaltung eines Interviewleitfadens mit dem/der Bürgermeister/in:

- Welche Themen bewegen Ihre Stadt?
- Wer spielt in der Stadt eine Rolle, wer nicht?
- Wenn ich an einem Tag möglichst alles über Ihre Stadt erfahren wollte, was sollte ich tun (wohin gehen, mit wem reden)?
- Wenn sie an die Zukunft ihrer Stadt denken, was fällt Ihnen dazu ein?
- Wo sind schriftliche Unterlagen über ihre Stadt zu finden?

Nach der Auswertung des ersten Interviews beginnt das Forscher-/-innen-Team mit der Datenerhebung in der Gemeinde.

3.1.3 Schritt 3: Datenerhebung in der Gemeinde

In diesem Verfahrensschritt werden die Wahrnehmungen und Bewertungen über die Gemeinde umfassend erhoben und bewertet - die in den Köpfen der Bewohnern ‚versteckten' Stadtbilder werden sichtbar gemacht. Es sind Bilder, die Hoffnungen, Wünsche, Ängste, Visionen, Vorurteile, Gefühle und Gedanken in Bezug auf die eigene Stadt enthalten. Es wird nicht erwartet, dass sich diese Bilder (Innenperspektiven) zwingend mit den objektiven Daten, die in einem späteren Arbeitsschritt ebenfalls erhoben werden, decken. Die Erhebung wird von einem interdisziplinären Forscher-/-innen-Team durchgeführt, das während der gesamten Erhebung Vorort anwesend ist. Es wird festgehalten, welche Themen zur Sprache gekommen sind, mit welchen Personen oder Gruppen Kontakt aufgenommen wurde, was über die Gemeinde erzählt wird, aber auch was beobachtet werden konnte und wie sich die Stimmung in der Gemeinde darstellt. Der Blickwinkel des Forschungsteams ist immer auf Gleichheit aller Bewohner/-innen und aller Bedürfnisse ausgerichtet.

Abb. 2: Die Fun-Fahre-Agenda: Ein Beispiel für aktivierende Öffentlichkeitsarbeit in Wien-Margareten.

Methodisch gehe ich in der ASD mittels Triangulation und Komparativer Analyse vor (ARBEITSKREIS QUALITATIVER SOZIALFORSCHUNG (Hg.); 1994; BOHNSACK; 1999; BREUER, 1996; CHARMAZ, 2006; FLICK, 2004; FLICK, 2007; GLASER & STRAUSS, 1998). Triangulation bezeichnet den Einsatz mehrer Erhebungsmethoden, deren Ergebnisse zueinander in Beziehung gesetzt werden, um zu qualifizierten Ergebnissen zu kommen. Die Komparative Analyse bezeichnet in Anlehnung an GLASER & STRAUSS (1998) den parallel laufenden Prozess der Datenerhebung, Datenanalyse und Dateninterpretation. Erhoben wird so lange, bis eine Verallgemeinerbarkeit der Ergebnisse mittels theoretischer Sättigung erreicht ist. Die qualitativ-zirkuläre Vorgehensweise endet, wenn keine neuen Informationen vorhanden sind; das Feld gesättigt ist. Die Via Regia der Stadtpsychologie, die ASD besteht aus einer Vielfalt an qualitativen Erhebungsmethoden, die eingesetzt werden, um zu wissenschaftlich abgesicherten Ergebnissen zu kommen. Darin enthalten sind der Empirische Stadtspaziergang, das Problemzentrierte Interview, Brainstorming, Fotodokumentation, Bildanalysen, sowie die speziell für Jugendliche entwickelte Methode - „write a movie script“ . Die ursprünglich auf FRANCESCATO (2000) zurückgehende „movie-script“-Methode macht Gemeindeanliegen sichtbar, die in den Familien thematisiert und in den Jugendlichen unbewusst vorhanden sind. Die movie scripts bilden in der Folge die Gemeindestimmungen ab und dienen dem Bewusstwerdungsprozess.

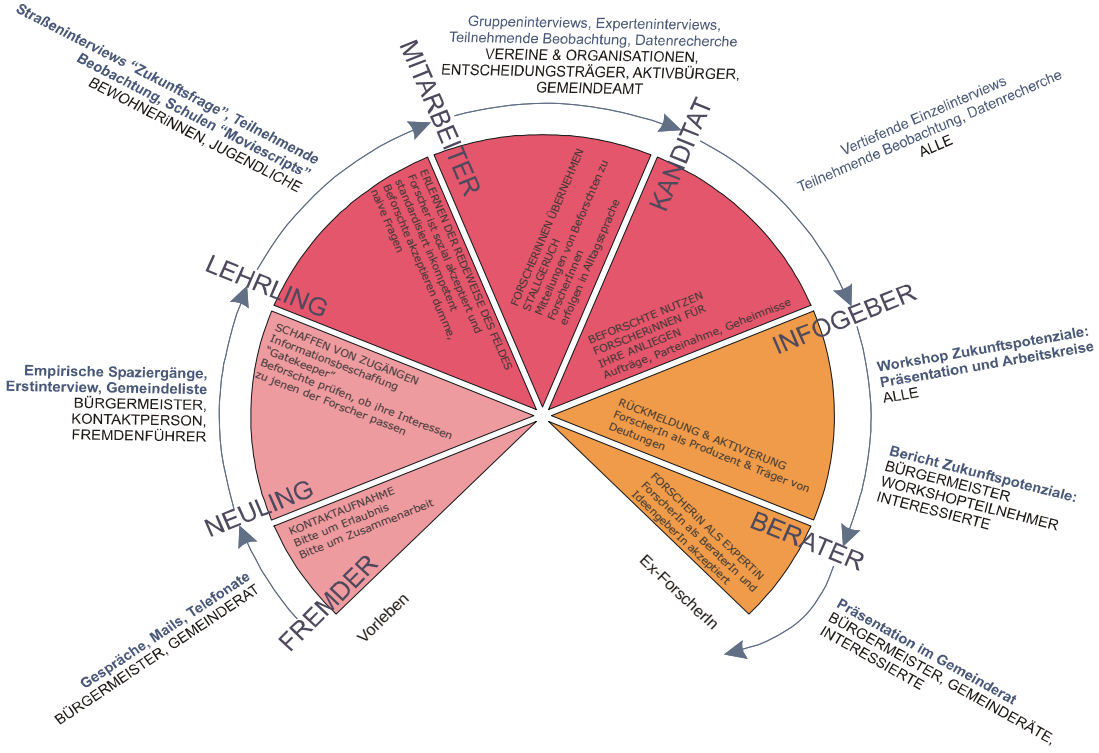

Abb. 3: Darstellung des qualitativen Forscherweges, wie er im Rahmen der ASD angewandt wird (EHMAYER, 2000C; vgl. dazu BREUER, 1996)

Die ASD enthält als zentrales Erhebungsinstrument die persönlich geführten Problemzentrierten Interviews.

Sie werden mit Einzelpersonen und mit Gruppen geführt. Je nach Größe der Stadt und Aufgabenstellung werden zwischen 150 und 350 Personen interviewt.

Zentrale Orientierungspunkte für Interviewfragen bei der Datenerhebung:

- Was ist typisch für Ihre Gemeinde?
- Hat Ihre Gemeinde ein Zentrum? Ein Wahrzeichen?
- Mit welchen fünf Eigenschaften würden Sie Ihre Gemeinde beschreiben?
- Welchen Menschen begegnen Sie in Ihrer Gemeinde? Wer fehlt Ihnen?
- Fühlen Sie sich in Ihrer Gemeinde wohl? Was stört Sie?
- Was zeigen Sie jemandem, der auf Besuch in Ihre Gemeinde kommt?

- Gibt es etwas aus der Gemeindegeschichte, das erzählenswert ist?
- Wenn Sie an die Zukunft ihrer Gemeinde denken, was fällt Ihnen dazu ein?
- Wo können Sie sich vorstellen, selbst etwas zu verändern?

Die Auswahl der Personen und Gruppen erfolgt in festgelegter Reihenfolge. Zunächst werden Personen im öffentlichen Raum, an den zentralen Orten der Gemeinde befragt (Außenrauminterviews). Es wird stets darauf geachtet, alle Bevölkerungsgruppen miteinzubeziehen und die Bedürfnisse unterschiedlicher Akteure/-innen spezifisch wahrzunehmen. Alle Interviewpartner werden im Rahmen der Erhebung gebeten, Personen zu nennen, die eine neue Sichtweise zu den bereits gesammelten Informationen und Themen einbringen können. Die Genannten werden anschließend kontaktiert und um ein Interview gebeten (Innenrauminterviews). Weiters - dies dient vor allem der Überprüfung wissenschaftlicher Vollständigkeit - wird ein sog. „Institutionen-Check“ durchgeführt: Erhobene Gemeindedaten werden mit aktuellen Gemeindedaten verglichen. Wenn das Forscher-/-innen-Team gute Arbeit geleistet hat, sind mindestens 80% der aufgelisteten Initiativen, Organisationen und Institutionen bekannt. Zumeist kennt das Forscher-/-innen-Team mehr Initiativen als durch offizielle Angaben zu finden sind, da sie über die intensive Arbeit Vorort Netzwerke erfassen, die über die klassischen Gemeindedaten nicht verfügbar sind. Oft sind diese auch den politischen Entscheidungsträgern nicht bekannt. Die Erhebung sieht weiters die kontinuierliche Erfassung von sog. Sekundärdaten vor. Dabei handelt es sich um öffentlich zugängliche Daten wie Wirtschaftsdaten, demographische Daten, Daten zur Anthropologie, Informationen aus Zeitungsartikeln, Fotos, Bilder, Chroniken, usw. Die Sekundärdaten werden für den Vergleich zwischen mündlich eingeholten Daten (subjektive Wahrnehmungen) und vorhandenen Fakten (objektive Daten) herangezogen. Dabei ergibt sich zuweilen durchaus Erstaunliches. So empfand bspw. die Bevölkerung ihren eigenen Wiener Bezirk als überaltert. Tatsächlich ist er lt. Bevölkerungsstatistik einer der „jüngsten“ Bezirke in Wien. Dies lag - so ergab die stadtpsychologische Analyse - an den alten Gebäuden, die den gesamten Bezirk „alt aussehen“ ließen. Die [Aktivierende Stadtdiagnose] sieht es als eine ihrer wesentlichen Aufgaben, die unterschiedlichen (unbewussten) Sichtweisen, die innerhalb eines Bezirkes, einer Stadt, einer Gemeinde vorhanden sind ausfindig und sichtbar zu machen. In dem soeben beschriebenen dritten Schritt der ASD ergänzen Phasen der Datenerhebung, Datenanalyse und Dateninterpretation einander. Nach der ersten Erhebungswoche kristallisiert sich stets ein spezielles Thema als Ausgangspunkt für weitere Erhebungen in einer Stadt heraus. Es wird dem Ursprung dieses Bildes nachgegangen, Fragen gestellt und Antworten gesucht. Woche für Woche wird dann das Bild über eine Gemeinde klarer. Wenn das Forscher-/-innen-Team keine neuen Inhalte über die Gemeinde mehr in Erfahrung bringen kann und das soziale Gefüge der Gemeinde ausreichend erfasst ist, endet die Erhebungszeit. Erfahrungsgemäß beginnt diese Phase nach rund drei Wochen intensiver Forschungsarbeit. Anzumerken ist, dass dem in der Gemeinde tätigen Forscher-/-innen-Team zunehmend mehr zugetraut und damit auch sukzessive mehr anvertraut wird. Voraussetzung dafür sind die positiven Erfahrungen der Bewohner, die diese mit einem professionell agierenden Forscher-/-innen-Team machen. Für die Datengewinnung ist das entstehende Vertrauensverhältnis so lange positiv zu bewerten, bis der Punkt der Einflussnahme erreicht ist: Zuerst werden Geheimnisse erzählt, dann wird versucht, das Forscher-/-innen-Team für spezielle Interessen zu gewinnen oder zu Anwälten für eine bestimmte Sache zu machen und zu guter Letzt werden ausdrückliche Erwartungen an das Forscher-/-innen-Team zur Verbesserung der Situation in der Gemeinde ausgesprochen. Dann ist der Zeitpunkt gekommen, an dem sich das Forscher-/-innen-Team aus der Gemeinde zurückzuziehen hat. Dieser Rückzug ist für beide Seiten zuweilen nicht ganz einfach aber unumgänglich.

3.1.4 Schritt 4: Analyse des Ist-Zustandes

Die Analyse des Ist-Zustandes wird vom Forscher-/-innen-Team durchgeführt, dauert rund ein Monat und findet in der stadtpsychologischen Praxis statt. Bei der Ist-Analyse werden die aus der Stadt mitgebrachten Ergebnisse (wie beim Problemzentrierten Stadtpsychologischen Interview bereits beschrieben) nach einem dreistufigen Verfahren kodiert. Zentrale Stadtaussagen (im Fachjargon „Kodes“ oder „Eigenschaften“ genannt) werden herausgearbeitet, nach Gruppen zusammengefasst, und nach inhaltlich-thematischen Schwerpunkten in Kategorien gegliedert. Bei der ASD ist die Analyserichtung von Beginn an bereits vorgegeben: In Richtung ‚Themen’: ‚Was’ ist Thema in der Stadt?“ und in Richtung ‚soziale Struktur’: „Wer prägt die soziale Struktur der Stadt?“.

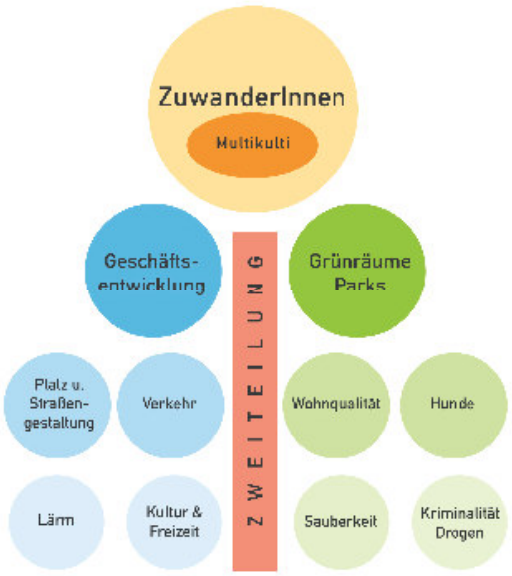

Abb. 4: Darstellung der Themenanalyse in Wien-Margareten.

Die Ergebnisse der Analyse erhalten in der grafischen Darstellung eine räumliche Position und gehen in die ‚Themenanalyse' und das ‚Kommunegramm' ein. Bei der Themenanalyse werden die inhaltlichen Kategorien anhand eines Stadtplans in eine räumliche Beziehung zueinander gebracht. In einer Stadt gibt es sowohl Themen, die die ganze Stadt betreffen, als auch ausschließlich stadtteilbezogene Themen. Einmal positioniert, können die Stadtthemen auf einen Blick erfasst werden, wie im folgenden ein Beispiel aus Wien Margareten verdeutlicht. Das Kommunegramm macht das soziale Gefüge einer Gemeinde sichtbar. Es bildet die Gemeinde als Ansammlung von Gruppen und Einzelpersonen ab, gibt deren Position, die Stärke und die Qualität der Beziehungen zueinander wieder. Voraussetzung für die Erstellung eines Kommunegramms ist die – im qualitativen Sinn – vollständige Erfassung der für die Stadt prägenden Personen, Gruppen, Organisationen und Institutionen. Stadtpsychologische Untersuchungen haben gezeigt, dass sich die stadtspezifischen Themen (Themenanalyse) in einem wesentlich kürzeren Zeitraum erfassen lassen als das soziale Gefüge. Dafür braucht es wesentlich mehr an Vorort-Kenntnissen und der zeitliche Aufwand ist größer. Auch die grafische Darstellung des Kommunegramms erfordert viel stadtpsychologisches Know-how. Es bedarf mehrere Anläufe, bis das endgültige Kommunegramm vorliegt. Das Kommunegramm ist eines der Kernstücke der ASD und eine wesentliche Grundlage für zukunftsfähige Beteiligungsprozesse.

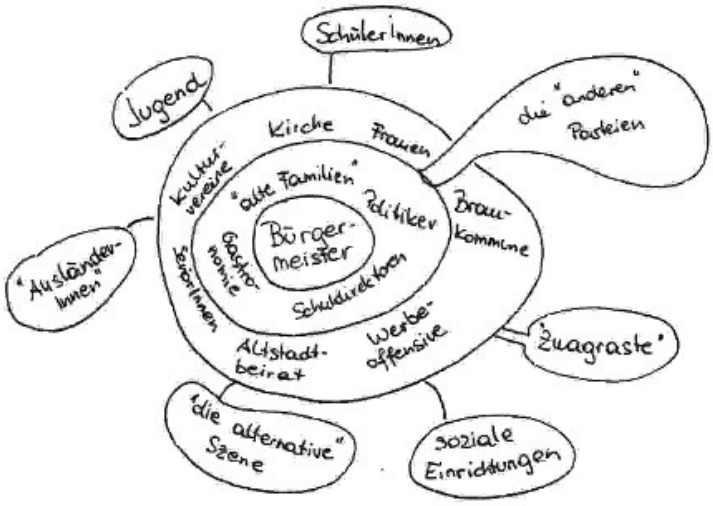

Abb. 5: Das Kommunegramm von Freistadt (Skizze)

Auszug aus dem Bericht ‚Zukunftspotenziale von Freistadt': Das Kommunegramm zeigt einen schalenartigen Aufbau, der sich um den Bürgermeister gruppiert. Nicht direkt verbunden sind: die Jugendlichen, die „Zuagrasten", die Migranten, sowie die „alternative Szene". Mit „Zuagrasten" sind diejenigen gemeint, die noch nicht lange in Freistadt leben. Es dauert einige Jahre bis man in Freistadt „dazugehört". Migranten kommen vorwiegend aus der Türkei und arbeiten im Straßenbau und in Steinbrüchen. Die alternative Szene umfasst hauptsächlich die Aktivitäten rund um den Verein Localbühne. Spannend erscheinen zwei Fragen: Inwieweit entspricht die soziale Struktur den örtlichen Gegebenheiten, also dem Stadtkern, der Stadtmauer und der Vorstadt? Und: Lassen sich die nicht direkt verbunden Gruppen als Potenzial für die Stadtentwicklung von Freistadt? Aus einem Kommunegramm, kann viel Information hinsichtlich des inneren Zusammenhalts einer Stadt abgelesen werden. Für weiterführende partizipative Stadtentwicklungsprozesse ist es insofern hilfreich, da es aufzeigt, welche Personen/Gruppen zu involvieren sind.

3.1.5 Schritt 5: Diagnose der Zukunftspotenziale

Die Diagnose der Zukunftspotenziale filtert die Themen aus, die in einer Stadt zu behandeln sind, um einen zukunftsfähigen Entwicklungsprozess zu starten. Zunächst gilt es herausfinden, welche Themen aus der Sicht der Bewohner für die zukünftige Entwicklung der Stadt von Bedeutung sind und welche Personen und Gruppen innerhalb der Gemeinde geeignet sind, diese Themen aufzugreifen und weiter zu tragen. Erst danach setzt die Expertise über die zukunftsbeständige Entwicklung der Gemeinde an. Die Stadtpsychologie entwickelt die Zukunftsperspektiven in einem gemeinsamen Prozess mit der Gemeinde.

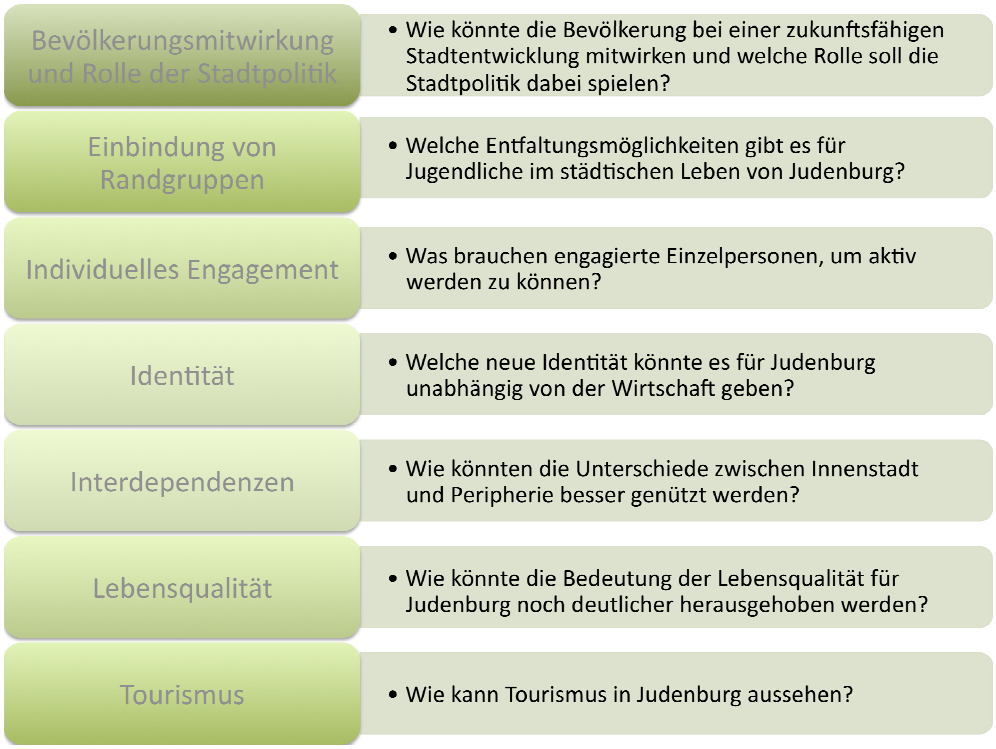

Abb. 6: Beispielhaft die Zukunftsfragen von Judenburg, die sich aus der ASD ergaben (EHMAYER et al, 2000a).

Ausgehend von den Kernfragen: „Welche nächsten Schritte sind für eine zukunftsfähige Entwicklung der jeweiligen Stadt notwendig und auf welchen Potenzialen kann sie dabei aufbauen?" werden im Laufe des Diagnoseprozesses Antworten gefunden. Diese ergeben sich gleichwohl anhand der in der Gemeinde erhobenen Analysedaten und der Expertise. Diese beiden Wissensfundi werden kombiniert, in Beziehung gesetzt und stadtpsychologisch interpretiert. Wichtig ist, dass hierbei nochmals genau auf Stärken und Schwächen der Gemeinde geachtet wird. Schließlich kann aufgezeigt werden, in welche Richtung es die Stadt ‚ziehen' muss, d. h. auf welche Entwicklung sich eine Stadt einlassen muss, so sie sich auf dem Weg in eine aussichtsreiche Zukunft machen will. Die Zukunftspotenziale einer Stadt sind jedoch zunächst keine Antworten, die in die Richtung weisen, wohin es gehen soll, sondern ganz im Gegenteil, sie werden zuallererst als Fragen formuliert. Denn der stadtpsychologische Ansatz geht davon aus, dass der Weg in

Richtung Zukunft nur auf Basis eines gemeinsamen Diskurses begangen werden kann. Als zentrales Element der Diagnose der Zukunftspotentiale fungieren die (drei bis sieben) Zukunftsfragen, die innerhalb der Stadt, ähnlich einem Leitbildprozess, zu thematisieren und zu bearbeiten sind.

Die Zukunftspotenziale sind als Wegweiser in die Zukunft zu verstehen. Und dies umso besser, je mehr Personen einer Gemeinde sich damit auseinandersetzen. Von stadtpsychologischer Seite wird jedoch nicht der Anspruch gestellt, dass sie die einzige Möglichkeit für eine aussichtsreiche Gemeindezukunft darstellen. Sie sind aber eine sehr gute Option, die einen lohnenden Prozess in einer Stadt auslösen können. Um einen ganzheitlichen Zugang zu einer Stadt – im Sinne von der Stadt als Wesen – zu erhalten, hat es sich bewährt, die jeweilige Stadt als Speise zu kreieren. War es bei der ersten Teildiagnose noch ausschließlich eine Hauptspeise (Tafelspitz mit Pommes in Wien-Alsergrund), so kreierten das Forscher-/-innen-Team und ich in Wien-Margareten zuletzt ein ganzes Gericht, mit Vor-, Haupt- und Nachspeise, das den jeweiligen Bezirk quasi kulinarisch wiedergibt. Jede Stadt verfügt über ihren ganz eigenen Charakter, zeichnet sich durch ihr unverwechselbares Wesen aus, und so gleicht auch keine Stadtdiagnose der anderen. Die Stadtpsychologie und das Forscher-/-innen-Team haben demnach die Aufgabe, individuelle Schwerpunkte zu setzen. Manchmal sind es dann die „besonderen“ Geschichten, die über die jeweilige Stadt erzählt werden und die in die ASD einfließen. Es kann sich aber auch um eine inhaltliche Vertiefung in bestimmte Stadtthemen handeln, die als literarischer Beitrag, von Stadtbewohnern verfasst, in die ASD eingehen. Es können auch weitere ‚Bilder' sein, die deshalb angefertigt werden, um der Stadtbevölkerung zu einem besseren Verständnis über ihre aktuelle oder zukünftige Stadtsituation zu verhelfen.

3.1.6 Schritt 6: Reflexionsgespräch mit dem/der Bürgermeister/in

Ausgestattet mit der Themenanalyse, der Analyse der sozialen Struktur und den Zukunftspotenzialen führt der Weg zum/zur Bürgermeister/in, um die Ergebnisse gemeinsam zu reflektieren, zu diskutieren und gegebenenfalls zu ergänzen. Es ist dies eine qualitätssichernde Maßnahme, eine reflexive Schleife, um die Ergebnisse an die Stadt noch besser anzupassen und damit eine maximale Gültigkeit (Validität) der AS-Diagnose zu erreichen. Bei diesem Gespräch wird der Zeitpunkt für die öffentliche Diskussion der Zukunftspotenziale (Präsentation) festgelegt und deren Ablauf strukturiert. Üblicherweise stellt die Stadt den Diskussionsort zur Verfügung und informiert in den lokalen Medien über Inhalt, Zeit und Ort der Veranstaltung. Das Ablaufdesign inklusive der Moderation Vorort sind Aufgabe der Stadtpsychologie.

3.1.7 Schritt 7: Öffentliche Diskussion der Zukunftspotenziale

Die öffentliche Diskussion der Zukunftspotenziale ist eine Informationsveranstaltung mit Workshopcharakter. Sie dient dazu, die Ergebnisse der ASD einer breiten Öffentlichkeit zur Kenntnis zu bringen. Außerdem ist das Interesse bei all jenen, die bei einer ASD mitgewirkt haben stets groß. Sie möchten gerne wissen, was dabei herausgekommen ist. Daher wird darauf geachtet, dass möglichst allen Menschen, die in der Stadt leben und arbeiten die Ergebnisse der ASD zugänglich gemacht werden. In der Stadt werden deshalb - gut sichtbar - Ankündigung und Einladung affichiert, es werden persönliche Schreiben verschickt und die Bewerbung der Veranstaltung über die lokalen Medien durchgeführt. Bei der Veranstaltung erfahren die anwesenden Personen schließlich die Ergebnisse der Diagnose und werden gleichzeitig dazu aufgerufen ihre Ideen und ihr lokales Know-how aktiv einzubringen und die dargestellten Zukunftsfragen noch einmal zu diskutieren und zu ergänzen.

Abb. 7: Diskussion der Zukunftspotenziale in Baumgarten.

Abb. 8: Der Bürgermeister von Baumgarten im Gespräch mit den Bewohnerinnen und Bewohnern.

3.1.8 Schritt 8: Befund erstellen

Am Ende jeder ASD steht der Befund. Kein Befund ist zwar wie der andere, da keine Gemeinde wie eine andere ist, aber es gibt Themen, die sich in jedem Befund finden. Wesentlich ist zunächst, dass der Befund in gut verständlicher Sprache geschrieben ist. Denn dieser wurde zwar mittels wissenschaftlicher Methoden erstellt, die werte Leserschaft ist aber nicht die Scientific Community, vielmehr soll er von den politischen Vertretern/-innen als Arbeitsgrundlage verwendet werden können und der Bevölkerung Einblick in Geschichte, Themen und Perspektiven ihrer Stadt geben. Der Befund ist ein ehrliches Bild über die jeweilige Gemeinde und ermöglicht seinen Leserinnen und Lesern, sich mit der eigenen Stadt in Beziehung zu setzen. Bemerkenswert an einem ASD-Befund ist, dass er im Unterschied zu quantitativen Analysen über mehrere Jahre Gültigkeit besitzt. Wahlen können dann zwar einiges in der Politlandschaft einer/m Stadt/Gemeinde/Bezirk verändern, an den Themenstellungen einer Stadt ändert erfahrungsgemäß auch ein politischer Wechsel nichts. Insofern kann die durchschnittliche Lebensdauer eines ASD-Befundes mit ca. 7 Jahren angesetzt werden.

3.1.9 Schritt 9: ABSCHLUSS: Übergabe des Befundes an den/die BürgermeisterIn & Präsentation im Gemeinderat

Der Befund wird dem Auftraggeber übergeben. Meist leitet der Bürgermeister/die Bürgermeisterin den Befund an den Gemeinderat weiter. Manchmal wird mir ermöglicht, die Ergebnisse des Befundes direkt bei einer Sitzung des Gemeindrates zu präsentieren.

4 RÉSUMÉ

Mit der Durchführung einer Stadtdiagnose können sich Städte und ihre Bewohner optimal auf einen partizipativen Stadtentwicklungs- bzw. Leitbildprozess vorbereiten. Mit den diagnostizierten zukunftsfähigen Potenzialen können Städte aus eigener Kraft jene Veränderungsmaßnahmen setzen, die es braucht, um eine hohe Stadt- und Lebensqualität dauerhaft abzusichern. Zur Erstellung der Stadtdiagnose werden lokale Akteurinenn und Akteure umfassend in den Erhebungsprozess einbezogen. Eine fundierte Stadtdiagnose kann nicht erstellt werden, ohne die Meinung jener zu kennen, die in der Stadt wohnen, arbeiten und Entscheidungen treffen. Die Erfahung hat gezeigt, dass sich – ausgelöst durch den stadtpsychologischen Befragungsprozess - die Kommunikation zwischen Politik und Bevölkerung zu verbessern beginnt. Die Menschen einer Stadt begrüßen es, wenn sie um ihre Meinung gefragt werden. Der Politik wiederum nützt es, um die Meinung der Bevölkerung fundiert bescheid zu wissen.

Emergence of suburban employment centres in German metropolitan regions: Impacts on commuter traffic, 1987-2007

Dennis Guth

(Dipl.-Geogr. Dennis Guth, TU Dortmund University, Faculty of Spatial Planning, Department of Transport Planning, August-Schmidt-Str. 10, D-44227 Dortmund, dennis.guth@tu-dortmund.de)

1 ABSTRACT

Over the past decades metropolitan areas became increasingly decentralised. The relocation of workplaces to suburban places has given rise to the emergence of 'new' employment centres, which generally reflect the multicentric nature of an urban landscape. The literature frequently claims that the formation of such centres shortens average commuting distances as people tend to relocate near or even within subcentres. Our results suggest that the majority of people did not come closer to their jobs, as the average journey-to-work distances significantly lengthened over time. Moreover, we can not find decreasing shares of suburb-to-core-city commutes, making us argue that factors other than intrametropolitan jobs-housing-proximities strongly influence where employees reside.

2 INTRODUCTION

During the last couple of decades metropolitan areas have experienced a rapid deconcentration of economic activities to suburban places. A review of empirical studies shows that the emergence of multicentric urban configurations occurred in many metropolitan regions throughout Europe, Asia and the USA. The results indicate that increasingly higher shares of metropolitan employment are concentrated in suburban clusters, nodes or edge cities outside the traditional urban cores (Anas/Arnott/Small 1998). Spatially, these 'new' centres are frequently located in the periphery along or in close vicinity to motorways. Functionally, they mostly do not include all functions of traditional urban centres. They rather may be specialised as office or retail locations (Einig/Guth 2005; Garreau 1991; Giuliano/Small 1991).

One of the recurring topics of this discourse is the interrelation between decentralised employment growth and the development of commuting patterns over time. The impact of subcentring on the journey-to-work has already been addressed in numerous papers (e.g. Alpkokin et al. 2005; Cervero/Wu 1998; Giuliano/Small 1991; Muller 1976; Parolin 2006). However, the evidence is disputed and far from being conclusive:

- Given the existence of a decentralised population within metropolitan regions makes some researchers argue that the suburbanisation of the labour force brings jobs and workers closer together. The spatial convergence of employment and housing locations goes hand in hand with higher shares of intrasuburban commuter flows which are usually associated to be shorter both in terms of times and distances (e.g. Lee/Seo/Webster 2006), thereby leading to more sustainable trip patterns within urban areas (e.g. Crane/Chatman 2003).
- Another strang of papers observed an increase in commuting in terms of distances, durations and/or volumes. These studies have shown that workers living within or close to subcentres do not necessarily have shorter commutes (e.g. Aguilera 2005); partly a reason of a growing number of dual-earner couples who usually fail to both relocate close to their working place (e.g. Cervero 1989). Moreover, some authors argue that restrictive urban land use regulations may prevent people from relocating closer to their workplace (exclusionary zoning hypothesis). As suburban municipalities often do not pursue a coherent policy with regard to jobs and housing aspects, urban spatial structures that minimise commuting may hardly emerge (e.g. Muller 1976).

While recent empirical research on the interrelation of employment suburbanisation and commuter traffic mostly focuses on US (e.g. Yang 2005), French (e.g. Aguilera 2005) and Dutch (e.g. Schwanen et al. 2004) metropolitan regions, there is a striking research gap regarding German literature (exceptions are: Guth et al. 2010; Siedentop 2007). The DFG/SNF-funded research project 'Spatial accessibility and the dynamics of commuting in Germany and Switzerland, 1970-2005' aims to contribute to this topic. The paper presents findings from our research. It examines the following hypotheses with a focus on German metropolitan regions:

- The deconcentration of workplaces to suburbia goes along with a 'decoupling' of the periphery from the traditional urban cores and leads to stronger internal linkages within suburban areas.

- The emergence of suburban employment centres is an outcome of the 'infill' of workplaces in the periphery of metropolitan areas. These centres are – besides the historic urban cores – privileged areas of attraction for commuters and might increase the probability of finding a job near or even within the place of residence. Multicentric urban configurations may therefore generate more travel-efficient commuting trip patterns across metropolitan regions ('co-location' hypothesis).

3 DATA

To examine the hypotheses described above, we use data on commuter flows provided by the Federal Statistical Office (German Census 1987) and the Federal Employment Agency (German Social Security Statistics 2007). The data contain information about in-, out- and internal commuting trips at the spatial scale of municipalities. In both data sets a commuter can be identified by the spatial separation of jobs and housing locations. All persons who do not work and live within the same municipality are considered to be crossmunicipality commuters. There is only in- and out-commuting if an employee crosses at least one municipal boundary on his/her way to work. If no boundary crossing occurs, the person is classified as local (internal) commuter. Both commuting matrices have been validated extensively during our prior work and a weighting factor for daily and periodically (non-daily) commuting activities has been introduced. The share of daily commuting trips by distance (km) has been deducted from the Census 1987. In the following sections we only consider daily commuting activities to avoid the distorting effect of long-distance commuting trips. Furthermore, we only consider employees subject to social insurance contribution due to missing information about self-employed and public servants in the commuter matrix of 2007.

4 DELINEATION OF METROPOLITAN REGIONS

Our study requires the identification of metropolitan areas as a framework for analyses. In the German spatial science literature the assignment of metropolitan boundaries frequently relies on the use of a-priori circular shapes (e.g. 60 km) using GIS-applications to buffer the administrative boundaries of the urban cores (e.g. Siedentop 2007). Several other studies use threshold values of in- and out-commuting intensities for describing the spatial expansion of commuter catchment areas of urban centres[1] (e.g. Herrmann/Schulz 2005). Our approach is similar to the functional definition of commuting regions proposed by the German Federal Office for Building and Regional Planning (BBR 2005). The delineation refers to the year 2007 and works as follows:

- *Identification of metropolitan cores*: First, metropolitan cores have been defined as municipalities having more than 500.000 inhabitants.
- *Identification of second order core cities*: All cities which have above 100.000 inhabitants have been defined as second order core cities. The metropolitan cores and the second order core cities constitute the set of large cities. All other municipalities have been classified as 'potential' suburban municipalities.
- *Identification of large cities' catchment areas*: The out-commuting intensity[2] values of all 'potential' suburban communities to large cities have been calculated using the commuter flow matrix of the year 2007. We checked for different cut-off values ranging from 5% to 10% of all workers within a municipality. The choice of the cut-off point generally determines size and expansion of an urban area (Killer/Axhausen 2009). After a systematic comparison of the different boundaries we finally decided to use the 7,5% threshold value as cut-off level for further analyses.
- *Creation of functional commuting regions*: All communities exceeding the 7,5% threshold value have been classified as suburban municipalities; all other municipalities have been classified as peripheral (non-metropolitan) communities, which had to be excluded from further delineation. In a last step, we finally allocated all suburban municipalities to their respective commuting regions by (i) selecting all commuting flows to large cities and (ii) comparing their values with regard to their out-commuting intensities. After having identified the prevailing flow to a respective large city (highest intensity) we finally were able to define a suburban municipality as being part of a specific commuting region.

[1] This method has also been carried out for US metropolitan regions (e.g. Berry/Gillard 1977).
[2] The out-commuting intensity is the share of out-commuters among all workers (employed residents) within a specific municipality.

Following this approach, we identified eight metropolitan regions with the core cities of Bremen, Hamburg, Hanover, Frankfurt a.M., Munich, Nuremberg, Rhine-Ruhr (= Cologne, Dortmund, Düsseldorf, Essen) and Stuttgart. Moreover, we identified 15 secondary urban areas. As metropolitan regions generally have enlarged over time (expanding commuter sheds), we decided to take a fixed boundary-delineation, as is often the case in this type of studies (e.g. Aguilera 2005).

Following this approach, we identified eight metropolitan regions with the core cities of Bremen, Hamburg, Hanover, Frankfurt a.M., Munich, Nuremberg, Rhine-Ruhr (= Cologne, Dortmund, Düsseldorf, Essen) and Stuttgart. Moreover, we identified 15 secondary urban areas. As metropolitan regions generally have enlarged over time (expanding commuter sheds), we decided to take a fixed boundary-delineation, as is often the case in this type of studies (e.g. Aguilera 2005).

Table 1 provides some key statistics highlighting structural differences among the metropolitan regions. The spatial expansion of the catchment areas and the location of large cities are shown in figure 1. Because of missing data (1987) with regard to workplaces, workers and commuter flows we were not able to delineate the metropolitan areas of the former German Democratic Republic. In the remainder of this paper, we only consider the municipalities of the West German 'Bundesländer'.

Region	Number of municipalities	Overall area [km²]	WP 1987	WP 2007	ER 1987	ER 2007
Bremen	154	8.977	565.612	605.072	577.350	593.170
Frankfurt a.M.	428	9.244	1.599.571	1.634.727	1.548.888	1.520.332
Hamburg	525	10.677	1.185.710	1.259.426	1.178.400	1.210.022
Hanover	192	8.063	820.442	800.642	813.259	778.614
Munich	379	11.401	1.301.749	1.443.504	1.264.563	1.353.870
Nuremberg	186	6.389	609.920	636.806	594.986	611.804

5 IDENTIFICATION OF SUBURBAN EMPLOYMENT CENTRES

Our study requires the identification of suburban municipalities which have above-average employment stockings. Prior studies have defined suburban centres in several different ways. Some papers use threshold values of employment densities and total employment, considering a subcentre to be a zone or municipality above a given minimum cut-off (e.g. Anderson/Bogart 2001; Giuliano/Small 1991; Giuliano et al. 2005; McDonald 1987). Others suggest more sophisticated approaches to avoid pre-defined (arbitrary) cut-off points. For instance, McMillen (2001) uses non-parametric estimation techniques to identify suburban centres as local peaks in employment density functions. A similar approach has been discussed in Craig/Ng (2001) showing the application of non-parametric specifications for the metropolitan area of Houston (Texas). Other studies refer to the use of spatial autocorrelation techniques to explore regional employment concentrations higher than the mean. The empirical application of such statistics has recently been shown for a selection of four Belgian cities (Riguelle/Thomas/Verhetsel 2007).

This paper follows the approach described in Parolin/Kamara (2003) and Parolin (2006). The methodology has been carried out twice for the metropolitan area of Sydney and works as described subsequently:

- In a first step we need to identify 'potential' subcentres for use in further analyses. A 'potential' subcentre can be defined as (suburban) municipality which has an employment stocking that is significantly higher than the national mean. The identification of above-average employment concentrations is based on the calculation of standardised employment values (z-scores). For each municipality employment data were thus standardised by subtracting the mean of all municipalities from its employment value and dividing the difference by the standard deviation. The body of municipalities which have values higher than 0 were then considered as 'potential' subcentres. In doing so, we identified 1.183 'potential' centres in 1987 and 1.313 in 2007.

- In a second step we confined the set of 'potential' centres by selecting only those municipalities which have a ratio of workplaces to workers (employed residents) greater than 1 resulting in 610 centres in 1987 and 680 in 2007. That means we only considered a municipality to be a subcentre if the respective community exhibits a surplus of in-commuters, indicating a superior attraction for employees. Furthermore, we only included those municipalities which have their location within the boundaries of the metropolitan regions as defined in section 4. After further having reduced the set of subcentres we finally identified 202 subcentres in 1987 and 265 in 2007. All other municipalities within the catchment areas' boundaries (except for the large cities) were assumed to be non-(sub)centres.

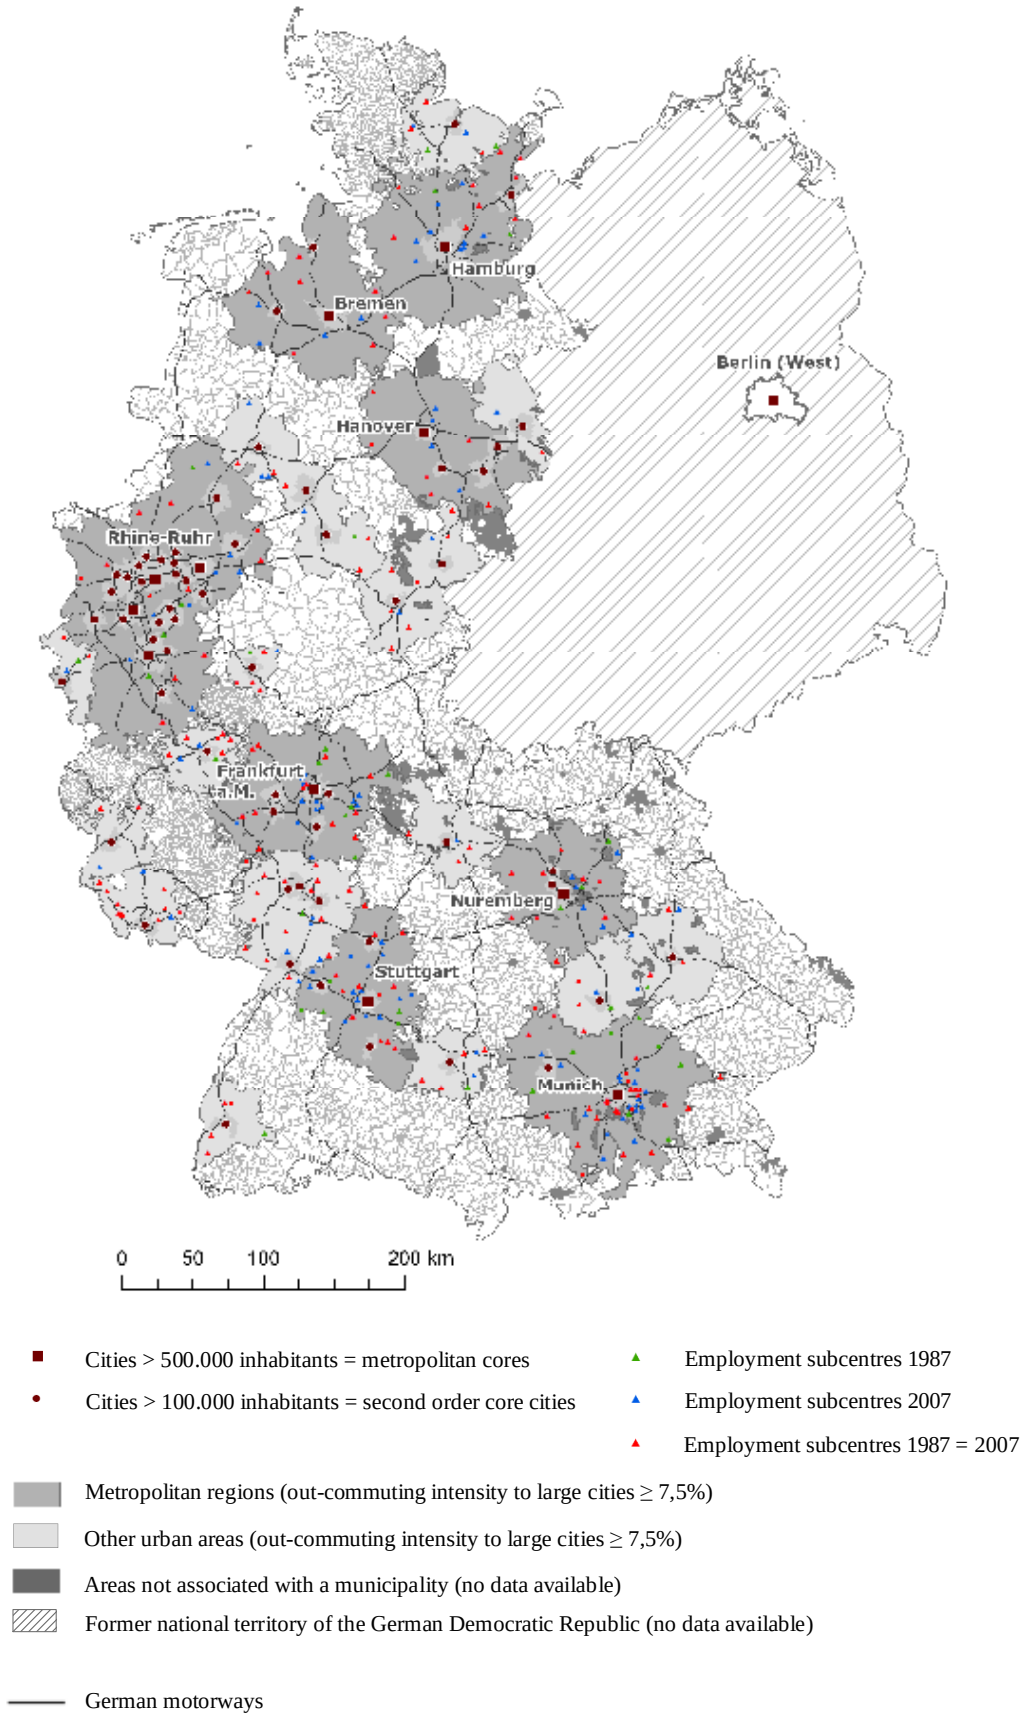

Fig. 1: German metropolitan regions (functional commuting areas) (Source: Own illustration. Data taken from the Federal Agency for Cartography and Geodesy)

Figure 1 shows the location of subcentres within the predefined boundaries of our study regions. Like in many European and US agglomerations, the majority of suburban centres has clearly sprawled along or in

close vicinity to motorways (e.g. Aguilera 2005; Anderson/Bogart 2001; Garreau 1991). Table 2 provides some key statistics with regard to the number of large cities and suburban centres. The table also contains information about the absolute and relative variation in the number of subcentres over time, highlighting a general increase in the number of suburban employment locations across all metropolitan regions. The results further indicate that many centres that have been identified in 1987 still exist 20 years later (1987 = 2007). While some of the 1987 employment subcentres drop out of the table in 2007 and some 2007 centres were below the national mean in 1987, several centres exist both in 1987 and 2007. The 'stability' of clustered employment through recent decades may generally reflect the relevance of strong agglomeration forces over time (Parolin 2006) and might as well support the argument of long-term persistence in metropolitan spatial structures.

Our further analyses proceed by generating statistics on workplaces, workers and commuter flows for the entire set of geographical subdivisions (large cities, non-(sub)centres and subcentres). Some caution is warranted in the cross-interpretation of the results (percentage changes) as some subcentres and non-(sub)centres are not identical in 1987 and 2007. However, the method applied in this paper allows us to check for the 'decoupling' and 'co-location' hypotheses, as we explicitly aim to examine commuting patterns for both 1987 and 2007. Given that subcentres represent the multicentric nature of an urban landscape we (i) expect higher levels of self-sufficiency within suburban municipalities (more internal commuting trips within subcentres and/or increasing shares of suburb-to-suburb commutes) and (ii) a shortening of commutes as firms may favour to move closer to their workforce.

In the following sections we first describe the changing geography of working and housing locations over time. We ask as to whether there is a significantly higher share of workplaces located within suburban municipalities in 2007 (section 6). In a second step we examine whether or not a significant proportion of residents came closer to their jobs, thereby leading to a 'decoupling' of the periphery and to decreasing amounts of commuter traffic over time (section 7).

6 CHANGING GEOGRAPHY OF WORKING AND HOUSING LOCATIONS

In this section we describe some major trends of metropolitan evolution since 1987. The focus is on morphological shifts such as the spatial development of employment and housing locations. In doing so, we are able to quantify the degree of spatial deconcentration for both economical and residential activities and can better assess the relevance of centred employment growth in German metropolitan regions. In this chapter we raise two specific questions:

- Is there evidence for employment suburbanisation between 1987 and 2007?
- If so, did jobs tend to cluster in centres or spread out across the urban landscape?

To answer these questions we calculated aggregate workplace statistics for the entire set of German agglomerations (table 3). The results indicate several striking features. First, it becomes clear that suburban municipalities gained importance as locations of employment across all metropolitan regions. The shares of large cities in the regional overall sum of workplaces declined in every single case, whilst the shares of

suburban municipalities increased without any exception. In all agglomerations the growth rates of suburban municipalities exceed the values for the large cities, i.e. a decentralisation of the workforce generally took place throughout German metropolitan areas.

A second key finding is that large cities still remain important locations of employment, despite declining shares of total employment. The percentages in the regional overall sum of workplaces (2007) are ranging from 33,5% in Stuttgart (lowest) to 63,6% in Rhine-Ruhr (highest), whilst the shares of jobs within subcentres accounts for 4,9% in Rhine-Ruhr (lowest) and 23,2% in Munich (highest). Comparing our data with the work of Parolin (2006) shows somewhat lower proportions of employment within German subcentres[3] . However, the addition of 63 centres across the entity of metropolitan areas has supposably affected the spatial economies of the study regions. As more and more workplaces tend to cluster within a small number of suburban municipalities, we agree with prior studies, assuming a general rise of multicentric urban growth throughout Europe over time (e.g. Gilli 2009).

Tab. 3: Aggregate workplace statistics, 1987-2007 (Source: Own computations. Data taken from the German Census 1987 and the German Social Security Statistics 2007)

Closer examination further indicates the significance of centred employment within German metropolitan areas. In order to study the spatial (de-)concentration of jobs within urban areas a simple measure of the morphological distribution has been calculated. We use Gini coefficients to investigate the degree of spatial dispersion in metropolitan employment. The index can take values from 0 to 1, and the higher the value, the more concentrated the workforce within each metropolitan region. The Gini coefficient (GC) is calculated as follows (municipalities have to be ranked ascending with regard to their share of employment within the respective region) [4]:

$$GC = 1 - \sum_{i=1}^{n} (u_i - u_{i-1}) \cdot (v_i + v_{i-1})$$

[3] The share of workplaces within identified subcentres accounts for about 38% in the Sydney metropolitan area (Parolin 2006).
[4] In the same way, we calculated Gini coefficients for the distribution of the workers (employed residents).

u_i: accumulated share of municipality i in the overall sum of all municipalities of a region
v_i: accumulated share of a municipality's i employment in the overall sum of all municipalities of a region
n: number of municipalities of a region

Table 4 reveals that all WP-GCs exceed a minimum of 0,75 (2007), indicating that a high proportion of the metropolitan workforce still remains concentrated within a small number of municipalities (see also table 3). Comparing the coefficients for 1987 and 2007 makes clear that the deconcentration of jobs has led to a more equal distribution of employment occasions across metropolitan areas (declining WP-GCs). However, the spatial diffusion of workplaces seems to be rather selective in the sense of that employment tends to cluster within a small number of centres (indicating the unbroken relevance of strong agglomeration forces). In no case there is any scattered (i.e. spatially extensive or sprawl-style) decentralisation pathway as reported for US metropolitan regions (e.g. Burchell et al. 1998). The dynamics in the pattern of employed residents show similar trends. As has been shown for workplaces, the results indicate deconcentration tendencies of residential activities (finding their expression in declining ER-GCs). However, as shown in prior studies, the overall distribution of residents tends to follow a more even distribution across space (e.g. Gilli 2009; Lee 2007; Siedentop et al. 2003). We confirm these prior findings by comparing WP- and ER-GCs for both points in time, showing somewhat lower values of ER-GCs throughout all metropolitan areas.

7 DYNAMICS OF COMMUTING

The spatio-temporal development of commuter traffic will be analysed in two steps: First, the dynamics of commuting linkages over time will be examined. By comparing the shares of in-, out- and local commuting trips we can assess whether or not a 'decoupling' of the periphery from the traditional urban cores did in fact take place between 1987 and 2007. In a second step we focus on the changes in average distances covered by commuters. In doing so, we are able to test the 'co-location' hypothesis, which claims that the emergence of multicentric urban configurations leads to a shortening of commutes over time.

7.1 Commuting linkages – 'decoupling' of suburbia from large cities?

After having shown the relevance of suburban growth patterns across German metropolitan regions we raise some more specific questions. As the arrival of 'new' jobs within suburban areas generally may have increased the probability for workers to find a job within suburban locations, we (i) could expect decreasing percentages of traditional (long-distance) suburb-to-large-city trips and/or increasing shares of (somewhat shorter) suburb-to-subcentre commutes. Moreover, the emergence of suburban employment centres may (ii) explain higher degrees of self-containment within these municipalities. We thus ask for two questions:

- Do the residents of suburban municipalities orientate towards subcentres?
- Can we observe increasing levels of internal linkages within suburban centres over time?

Table 5 highlights several important findings. One of the most striking features is that the proportion of crossmunicipal commuting trips (in- and out-commuting) has significantly increased across the entire set of metropolitan areas during the past two decades. Compared with the situation in 1987 we can find increasing shares of employees living in a subcentre and working in a large city. Moreover, we can identify higher

shares of people living in a subcentre and working in another subcentre, as well as higher shares of people living in a subcentre and working in a non-(sub)centre and even higher shares of people living in a subcentre and working outside the boundaries of their respective metropolitan area (external commuters). At the same time the proportion of internal commuting trips (people who both live and work in the same subcentre) declined markedly over time, which makes us reject the second question raised above. As for suburban centres, similar dynamics can be found for large cities and non-(sub)centres[5] . Our results thus confirm a trend widely noticed among European transport researchers, that workers expand their activity spaces and do not overwhelmingly tend to live and work within the same municipality[6] (e.g. Aguilera 2005; Bontje 2007; Moser 2007). This makes us assume that the distances covered by commuters may not have declined during recent decades, as claimed by the 'co-location' hypothesis. We provide some deeper insights in the next section.

Tab. 5: Dynamics of commuting linkages, 1987-2007 (Source: Own computations. Data taken from the German Census 1987 and the German Social Security Statistics 2007)

As already has been pointed out for French metropolitan areas (Aguilera 2005), table 5 also shows that the majority of people living in a subcentre work outside their places of residence, giving us some more indication to reject the questions raised above. It further becomes apparent that the main out-commuter flows are still directed towards the higher level cities in the urban hierarchy (large cities). This is true for both categories of suburban municipalities; i.e. subcentres and non-(sub)centres. Comparing 1987 with 2007 indicates that the situation was even more distinct in 2007 than 20 years before. We thus find increasing rather than decreasing shares of traditional suburb-to-large-city commuting trips over time.

[5] There is only one exception in the case of Munich: The share of employees living in non-(sub)centres and working in large cities declined from 1987 to 2007.

[6] More generally we can speak of intensifying commuting patterns over time as already have been observed by Bontje (2007) for the region of Amsterdam. His main findings are a constantly high level of in-commuters into Amsterdam and a steady increase in reverse commuters with jobs in the newly developed suburban employment centres. This pattern, which he describes as 'exchange commuting', clearly suggests a qualitative mismatch between job supply and job demand.

At the same time as large cities became more attractive as destinations for suburban employees, the peripheral type of suburb-to-suburb trips gained importance, too. We thus agree with Killer/Axhausen (2009) who suggest that commuting linkages are becoming more and more complex over time. We further support the argument of Moser (2007) claiming that the commuters' destination choice became increasingly arbitrary through recent decades. All these findings make us reject the 'decoupling' hypothesis. Neither, can we identify more or less self-reliant 'villages' in the urban fringes nor can we find declining linkages between the traditional cores and suburban municipalities as reported for several US agglomerations (Lee/Seo/Webster 2006). However, we find evidence for a marked increase in disperse commuting patterns, which one may interpret as a general outcome of the infill of 'new' job opportunities within suburban locations ('urbanisation of suburbia'). In the following section we study as to whether these trends led to more sustainable short distance trip patterns over time.

7.2 Commuting distances – shortening of the journey-to-work?

In this chapter the distances covered by commuters will be analysed. Information about the real distances travelled by crossmunicipal commuters are missing in the data sets. As often is the case in this type of studies we hence calculated straight line distances between the centroids of the working and housing municipalities (e.g. Siedentop 2007). The distances covered by local commuters are estimated as well. A complete description of this approach can be found in Guth et al. (2010).

Table 6 shows the average distances covered by in- and out-commuters both for 1987 and 2007. We additionally calculated the mean distances for the sum of all commutes, i.e. in- and out-commuting trips including internal commutes. This chapter particularly aims at testing the 'co-location' hypothesis. As firms may have relocated where employees reside or, vice versa, as people might have relocated closer to their workplaces, we could expect somewhat shorter commutes within metropolitan areas. Again, we raise some specific questions:

- Can we observe significantly lower in-commuting distances to suburban employment centres over time?
- Did the emergence of suburban centres lead to shorter trips in the study regions?

We start by comparing average in-commuting distances of large cities with those of subcentres and non-(sub)centres. There has already been a broad discussion on whether or not working in central cities is associated with above the mean distances. Our findings clearly suggest that in-commuters of traditional urban cores have longer work trips than people working in subcentres or non-(sub)centres. This is true both for 1987 and 2007, and for the entire set of metropolitan areas. Our results are consistent with Cervero/Wu (1998) and the recent work of Siedentop (2007) for a selection of five German metropolitan regions. Moreover, we confirm that commuting trips to employment subcentres are somewhat longer than commutes to jobs within noncentred employment locations. This again is true for both points in time; but not for the region of Hanover[7].

To finally answer the questions raised above we need to analyse the shifts in commutes over time. Table 6 indicates that journey-to-work trips lengthened among all types of municipalities from 1987 to 2007. To return to 'co-location': As more and more people live and work within suburban places, we expected to find somewhat shorter commutes on average. But people obviously do not live closer to their jobs than 20 years before. On the contrary there is an increasing spatial separation of homes and workplaces in all municipality classes[8]; moreover, the regions' total average distances increased significantly over time. Some caution is needed as the tc-values are highly dependent on the share of internal commuters, who cover distinctly lower distances than in- or out-commuters on average. As shown in section 7.1 the share of local-commuters declined markedly over time, providing some explanation why the average distances rose as vast as shown in table 6. However, our results are in line with prior studies from Germany and abroad (e.g. Aguilera 2005;

[7] Referring to Giuliano/Small (1991) we can provide a possible explanation: As large cities and subcentres generally have high concentrations of jobs, they do not only draw workers from their adjacent municipalities but from a wider geographical space. Hence, a significant proportion of people working in a major centre requires longer average commutes and, thus, contributes to the existence of large-scale commuter sheds.

[8] Parolin (2006) visually determines the spatial spread of trips to suburban centres using GIS-flowmap applications. His results show a general increase in trip lengths and an expansion of overlapping commuting areas since 1981. His findings make him argue that the idea of self-containing suburban municipalities is *"indeed a long way off as a planning goal"* (Parolin 2006, p. 11)

Cervero/Wu 1998; Guth et al. 2010; Parolin 2006; Siedentop 2007). All the findings presented here lend weight to the argument that the 'co-location' hypothesis does not hold for German metropolitan regions and makes us come to the conclusion that the emergence of multicentric urban configurations has not given rise to shorter commutes on average.

8 SUMMARY AND OUTLOOK

This study has examined the role of suburban employment growth on the evolution of metropolitan commuting patterns over the past two decades. The paper focused on three specific topics: First, the identification of major employment subcentres across German metropolitan areas. Second, the question of whether or not the deconcentration of workplaces goes along with a 'decoupling' of the periphery from traditional urban centres and, third, the validity of the 'co-location' hypothesis for German agglomerations.

The interrelations between decentralised employment growth and the journey-to-work have already been addressed in numerous papers (especially USA, France, Netherlands). However, the evidence is disputed and far from being conclusive. Our empirical findings suggest that the decentralisation of employment has not led to a 'decoupling' of suburban municipalities from their respective urban cores. Neither found we higher numbers of self-reliant subcentres in the periphery of agglomerations, nor were we able to detect a decline of commuting linkages between cores and suburban centres over time. Moreover, our results suggest that the decentralisation of the workforce did not favour to bring more people closer to their jobs, as the average journey-to-work distances lengthened over time. All these findings made us reject the 'co-location' hypothesis[9]. We agree with Parolin (2006) and come to the conclusion "that factors other than proximity to

[9] As we focused on the investigation of average commuting distances exclusively, we have to amend that the empirical verification of the 'co-location' hypothesis frequently bases on the examination of commuting times, too. E.g. Gordon/Richardson/Jun (1991)

workplace have influenced and will continue to influence where workers reside. It is of paramount importance for metropolitan and transport planners to better understand what these other factors are likely to be if we are to move towards achieving sustainability" (Parolin 2006, p. 14).

The results presented in this paper shed a first glance on the dynamics of commuter traffic in German metropolitan regions since 1987. In order to broaden the empirical basis and to allow more general conclusions, additional analyses on the correlation between spatial development of employment, jobs-housing-proximity and commuter traffic will be necessary. Future work will extend on other urban regions and on an additional point in time (Census 1970). Moreover, it is intended to use road network distances instead of straight line distances to estimate the distances covered by commuters more precisely.

ACKNOWLEDGEMENT

We would like to thank the German Research Foundation (DFG) and the Swiss National Science Foundation (SNF) for funding this work as part of the project 'Spatial accessibility and the dynamics of commuting in Germany and Switzerland, 1970-2005'. This project is jointly carried out at the Department of Transport Planning at TU Dortmund University and the Institute for Transport Planning and Systems at ETH Zurich.

studied trends in US agglomerations between 1980 and 1985 and found a significant decrease in mean commuting times, despite considerable metropolitan urbanisation processes during the same period. The finding that the traffic increase associated with these urbanisation processes did not involve increasing commuting time burdens is interpreted as a 'commuting paradox'. They explain their results by a shift from radial commute trips, which are likely to take place on congested roads, towards more peripheral flows within suburbia. We currently prepare road travel time matrices for use in further analyses. These data allow us to examine the question whether or not the suburbanisation of workplaces has given rise to constant or even lower intrametropolitan commuting times during past decades.

EURO 2012 in Poland as a catalyst for change and testing ground for new urban management tools

Magdalena Rembeza,Lukasz Pancewicz

(Magdalena Rembeza MArch, Ph.D. Technical University of Gdansk, Poland, e-mail: magrembe@pg.gda.pl)
(Lukasz Pancewicz MArch, Technical University of Gdansk, Poland, e-mail: lukaszpancewicz@gmail.com)

1 ABSTRACT

UEFA decision from April 2007 to grant the hosting of EURO 2012 to Poland and Ukraine came not only as a significant benefit but also as a considerable challenge for Polish Authorities. The enormous organisational task including construction of new stadiums in four major cities as well as modernisation of transportation and urban infrastructure has to be accomplished in a relatively short time span. Not surprisingly the authorities branded EURO 2012 as a "civilizational project" considering the championship as a stimulus for the development of the country. A series of special legal, organisational and fiscal mechanisms have been implemented in order to facilitate provision of the required development. Municipal governments of the participating cities are also trying to take maximum advantage of the given chance by managing complex infrastructural projects and promoting designated areas in close proximity to the stadiums. Yet the key question of long-term economic and social effects after EURO2012 remains open for debate.

The presentation focuses on the overview of special legislation, organization and financing of EURO 2012 development agencies. The key development projects in major cities of Warsaw, Gdansk, Wroclaw and Poznan will also be discussed in the context of management, implementation and problems concerning large-scale complex urban projects as well as their relationship with their regional and local context.

2 INTRODUCTION

2.1 Euro 2012 as a catalyst of the procedural change

The UEFA European Football Championships EURO 2012 to be hosted by Poland and Ukraine allow to critically examine how the new, extraordinary implementation mechanisms introduced to enable the organization of a mega sport event (Preuss, 2005) affect urban policy in post-socialist countries. Specific context of this event is reflected by the rethorics of Polish authorities describing EURO 2012 as 'civilizational boost' or 'civilizational chance'. In such context a sport event becomes accelerating power for development of infrastructure and reduction of the existing civilizational underdevelopment (in comparison to the Western countries). Similar processes occurred as part of preparations to the Olympic Games in Athens in 2004 or football championships in Portugal 2004.

Examination of this point of view leads to special development mechanisms which were created for the purpose of enabling the development of the large scale urban projects. To understand fully the degree of change it will also be necessary to study how private capital was involved in the process and how the large-scale projects, which are often autonomous urban islands of rapid development, affected the urban development policy. Subsequently, this article focuses on issues closely related to the development and investment policy: the operational, legal or physical dimension of the urban change motivated by Euro 2012 championships. It is noteworthy that in Poland this event is not only considered as a challenge but academic, political and business observers also think of it as of a testing ground for new practices.

Preparations for Euro 2012 are one of the best examples of effects of globalization on the development practice – transfer of Western practice in terms of financing, organization and management of large-scale projects. The mobilization of the skills and resources was justified by relatively short deadlines, scale and extent of the projects. Former Polish governments had bad experiences of failures and lengthy development of the past projects, such as national motorways. The pressure on the government to meet the challenge had justified introduction of extraordinary mechanisms designed to speed up delivery of the projects. This decision is similar to global practice of finding the 'procedural shortcuts' that were used during the organization of other mega events (Preuss, 2005).

2.2 The mega event and participating cities – the stadiums as local flagship projects

The mega event considered from the local perpective requires additional examination of how the participating cities (Warsaw, Gdansk, Poznan and Wroclaw) could benefit from the chances granted by Euro 2012. The issue of the sport grounds development is often discussed in Polish debates as important in the

context of long-term urban sustainability and vitality of these areas. In majority of the cities the stadiums are considered as ‚flagship projects' and the attendant grounds as future development areas of the cities. Almost all of the Polish projects are judged against urban strategy pursued by London's ODA (Olympic Development Authority) embodied in its 2012 Olympic Park Masterplan. The overall strategic aim to ensure that 'life after mega event' of the urban districts in which the championships are to be held is often quoted as a reference in this regard.

Critcal assessment of all Polish projects indicates that in contrast to British practice, their future is more likely to be determined after the games. Some of the municipalities have been struggling to establish a long-term viable strategy for the development of these lands considering them as a long-term development potential. The weakness of local and national authorites in establishing a strong long-term urban strategy is illustrated by "The Stadium City" project in Warsaw. The overall masterplan designed in 2008 has never progressed into any viable implementation strategy and its concept is still debated by the participating parties. Equally Gdansk authorities consider development of the grounds in the vicinity of Baltic Arena but this potential is still dormant. Both case studies are discussed below.

3 'SPECIAL ACTS' AND PUBLIC 'SPECIAL PURPOSE VEHICLES' AS NEW LEGAL AND ORGANIZATIONAL STRUCTURES ESTABLISHED FOR EURO 2012

3.1 UEFA EURO 2012 Football Championships Tournament Preparation Act of the 7th of September 2009

One of the most important steps in the implementation of the projects for Euro 2012 was introduction of the UEFA EURO 2012 Football Championships Tournament Preparation Act on the 7th of September 2009. This bill enabled creating new development mechanisms, which supported the work of the highly politicised Organizational Committee established by the PM Jaroslaw Kaczynski and chaired by the high ranking governmental and sports officials. New structures created on foot of the Act were focused on business-oriented and managerial aspects of the preparations.

The Act had been colloquially called as 'A Special Act' (Polish: 'specustawa') reflecting its exceptional and interventionist character in the Polish legal system. It was not the first time that the government called for the special legislative measures. One year earlier a Special Roads Act had been passed, enabling a speeded-up delivery of the roads infrastructure[1]. The uniqueness of Euro 2012 Act was that it had established a legal basis for the organization and functioning of the designated Special Purpose Vehicles (SPVs). These publicly owned companies were tasked to develop key infrastructure and act as a local organizer of the local Euro 2012 events.

Establishment of these companies is in many apects similar to the British concept of Urban Regeneration Companies (URC). Polish companies are business-like entities, staffed by professional managers and controlled by the management boards. The SPVs were created to perform specific urban development duties. They are allowed by law to purchase and develop the land, procure tenders and act as a substitutionary investor. They are accountable to the local authorities or the State. Similarly to a private market SPVs their Polish counterparts can offer increased financial flexibility. The other unique aspect of the Polish SPVs is that they are allowed to by-pass the statutory planning and Compulsory Purchase Order (CPO) procedures due to their special legal status.

The Act specified that the SPVs should be established as a publicly owned company under the supervision of the Department of Sport or in some exceptions by the municipal government of the cities organizing the event. The entities created on the foot of the Act were established to:

- coordinate the event on the national scale - PL 2012,
- design and build the stadiums and the attendant grounds - National Sports Centre in Warsaw or Bureau of Euro 2012 Development Gdansk (Polish: BIEG 2012) in Gdansk,
- develop the communal infrastructure – for example Communal Developments Euro 2012 Gdańsk (Polish: GIKE 2012);

[1] Dz. U. Nr 154 z 2000, poz. 958

One of the most important benefits of the organizational model of the Euro 2012 Act was that it granted the public bodies a possiblity to engage the mechanisms of financial engineering available to the SPVs. Initially the legal status of the SPVs limited the access to the sources of financing other than public budgets. According to the initial version of the Act[2] the developments for Euro 2012 were to be financed primarily by the national budget, participating municipalities and EU structural funds in accordance with Long-Term Investment Plans (Wieloletnie Plany Inwestycyjne). Polish Public Finance Act of the 27th of August 2009[3] limited the amount of debt that can be taken by the public authority. This particular issue created a difficulty for the municipal government of Gdansk, whose budget could not provide covering the cost of Baltic Arena stadium. The attempts to attract private investment have been unsuccesful leaving the deficit of approx. 378 billion Zlotys.

Subsequently the Euro 2012 Act was changed after successful lobbying by Gdansk authorities, enabling some substantial changes to the legal status of the SPVs. The new Act allowed the companies to change the status of their developments from the delegated public investments to their own statutory tasks. In accordance to the new Act the lifespan of the SPVs could be extended. This new status enables them to operate the stadiums that they will have built after the 31st of December 2012. These changes lended a greater financial freedom to the companies allowing them to pursue other sources of financing such as credits or emission of development bonds. Gdansk selected this route and in 2009 arranged the emission of the municipal bonds. It was the only municipal government that decided to gather the funds for completion of the stadium using this route.

It is worth mentioning that not all of the infrastructure is delivered by the SPVs. Some of the large national level projects such as motorways, national roads, railroad improvements or the airports are built by the offical state-owned or quasi-public agencies such as Polish National Railways (PKP SA) or Polish National Roads and Motorways Authority (GDDKiA).

3.2 New delivery mechanisms created by the Euro 2012 Act and the changes to the legal system

The succesful organization of the UEFA EURO Championships in Poland depends on the timely delivery of significant amount of infrastructure. The projects supporting the event comprise inter alia roads network, railroads, IT networks, hotels and security networks. These infrastructural improvements are often considered as one of the long-term, ‘physical‘ benefits of the mega events (Oldenbloom, 2006). In this context the improvements to the legal mechanisms, responsible for delivery of these projects was of particular importance in Polish context.

All of the 136 key infrastructural projects have been designated and specified in the Regulations to the principal Act. The designated projects could benefit from special planning and CPO procedures, guaranteed by the Act.

The Euro 2012 Act covers four main areas of intervention, including:

- Accelerating tendering procedures
- Simplification of the planning procedures for the designated EURO 2012 projects
- Simplification of the Compulsory Purchase Order procedures
- Enabling the Public Private Partnerships and inclusion of the private projects (IT networks or Sports accomodation facilities) as Euro 2012 designated developments

Increased focus on these aspects of the investment process reflected the potential areas of contention, which could cause significant delays in the projects. The inclusion of private projects was one of the disputed topics since all of the designated project enjoyed a „public work“ status and simplified planning procedures.

Not all of the proposed improvements were introduced. One of the unsucessful changes was an attempt to grant the SPVs the right to use simplified tender or single-source procurement procedures without having regard to the premises required for a particular type of services such as construction works. Proposed solutions were not compliant with the EU directives of fair competition. Moreover, according to the EU

[2] Section no. 2 of the Euro 2012 Act.
[3] Dz. U. Nr 157 poz. 1240 and Dz. U. Nr 157 poz. 1241

directives the public owned SPVs were required to use tendering procedures. Finally the proposal was omitted. Review of the Public Tenders Law in 2008 resolved some of the issues. In the context of Euro 2012, one of the main risks associated with the old tendering procedures were appeal procedures. According to the 2004 Act the appeals were to be decided by the District Courts. New procedures for construction works allowed much quicker resolution of the contested matters by the National Appeal Boards. Addtionally, Ministerial Regulations on Appeal Procedures of the 2nd of October 2007 specified that all the projects of the significant national importance were eligible for the quicker route.

One of the most significant improvements was the introduction of special planning decision for the designated Euro 2012 projects. The Euro 2012 Act established administrative procedures which were to act independently of the Polish planning system. Poland as other European Union member states run a ‚plan-led' system requiring preparation of a valid Local Area Plan prior to development of the land. One of the main benefits of this system was that it allows to by-pass the standard planning controls. This procedure is similar to the other procedure – location decission for the public works development, allowed by the Planning and Development Act of the 27th of March 2003. The main difference between these two models is that in case of Euro 2012, the decission is granted by the Voivodship and not by the local authority. The Voivod is a regional representative of the central government and his duties include coordination and supervision of the local authorities' performance of their duties. The chances for the public participation are also greatly reduced in these new procedures.

The other equally important change included the unification of new location decision with the Compulsory Purchase Order procedures. This mechanism allowed not only to shorten the time required for purchase but also to gain the freehold of the building sites by the SPVs. In case of the land for designated Euro 2012 project a new law specifies the time required to reach the agreement with the landowner as two months. If this agreement is not reached the company can enter disputed property to commence the works.

4 FINANCING THE DESIGNATED EURO 2012 PROJECTS AND INVOLVEMENT OF PRIVATE CAPITAL

According to the initial version of the Euro 2012 Act all of the designated projects would be financed by the central and municipal budgets as well as non-refundable EU help, mainly the structural funds. Changes to the Act in 2009 created opportunity to use other sources of financing including private capital. These changes were dictated by the decision to include some of the private market developments on the designated projects list.

The way in which financing of Euro 2012 was organized enabled to involve the governmental budget in development of the large projects of the national importance – roads, railroads and airports. Significant number of these projects had been planned independently of the Football Championships. According to „The National Roads Investment Programme 2007 – 2012" prepared in 2007 the Department of Infrastructure assigned 165 billion Zloty to the new roads projects, of which 22 billion were diverted to the designated Euro 2012 projects. Majority of the infrastructural projects could be financially supported by the EU structural funds – particularly from the operational programme ‚Infrastructure and Environment" - as well as the Regional Operational Funds. The analysis of the Department of the Regional Development indicated both national and municipal projects as eligible for EU help.

Financing of the stadiums in four major cities – Warsaw, Gdansk, Poznan and Wroclaw - could not be achieved with EU funds. On the basis of inital agreements between Department of Sports and local governments, majority of the funds had to be collected by the municipalities. The National Stadium in Warsaw was the only stadium funded entirely by the central budget. Central government assigned a designated subsidy of 364 billion Zloty to support the development of the municipal stadiums. For example a total estimated cost of the Baltic Arena in Gdansk reached 645 billion Zloty, while the government assigned the subsidy of 144 billion Zloty. On averge the subsidies covered approximately 20% of the total cost of the projects. The remaining amount had to be covered by the municipalities[4].

So far the preparations to Euro 2012 proved the weakness of the procedures involving the private investment in the larger elements of the key infrastructure. This problem became apparent when none of the stadium projects did not manage to attract any private funds. One of the main reasons of this situation was general

[4] Stańczyk J."After the Meeting with UEFA We Have to Pay More", www.trojmiasto.com.pl, 4th of April 2008

lack of trust to PPP procedures amongst local governments and private investors. This distrust was caused by the character of the delivery mechanism specified by the Public Private Partnerships Act of the 28th of July 2005, which was generally considered as overly complicated and prone to the charges of corruption by the public authorities. The situation improved greatly with the review of the Act of the 5th of December 2008. Nevertheless, the new act was introduced too late to have any effect on the delievry of the stadiums. The act can still help of the delivery of other public infrastructural projects as the indebted municipal governemnts will seek for alternative sources of funding.

The aforementioned situation required the majority of the municpal authorities to search for other methods of gaining the funds for the development of their projects, as the emission of bonds or sale of naming rights. The high estimades of the management costs of the built stadiums, which will be a burden of the future municipal budgets, also forces the local governments to pursue more active strategies for funding.

One of the examples of such attempts is illustrated by Gdansk, which sold the naming rights to the Polish Energy Group for 35 million Zlotys and considers other options including using the stadium for mass concerts. In February 2010 local Councillors invited members of Commerzbank Arena management team, responsible for a number succesful large scale events for consultations. In this context the amendment of Euro 2012 Act enables some new opportunities for the management of the stadium. The analysis prepared by the Gdansk authorities highlighted at least two potential models. One of them considered the maintaining of the public character of the company owning the stadium and appointment of the private partner to manage the stadium. It is the same model as the one used by Frankfurt's Commerzbank Arena. Other option quoted by the offcials was full privatization of the SPV in a similar manner to Veltins Arena in Gelsenkirchen, which is owned and managed by a sports club - FC Shalke.

It is worth mentioning that in European context local stadiums function as the sports arenas for local football clubs (Oldenbloom, 200x). Gdańsk is no different and 44,000 seater PGE Arena will be a home stadium of Polish Premier League club - Lechia Gdańsk. The question of the long term viability of this arrangement is open for debate. On average Premier Leaue match in Poland attracts approximately 7,500 supporters.

UEFA Euro 2012 Championships will remain as a mega event, which preparation will largely be financed by the public budgets. Lack of the private investment can be explained by the absence of positive experiences of Public Private Partnerships and faulty legal mechanisms. Lack of trust in PPP, flaws in Polish legal environment of large scale investment with private funding and short deadlines led one of the prominent manager to state that „Stadium in Gdańsk is too serious matter, to experiment".

One of the main consequences of Euro 2012 apart from improvements to the law may be the increasing cooperation between the public and private sector after the 2012 championships., given the increasing level of the public debt incurred as the effect of preparations to the tournament. Unsuccesful attempts to create a PPP mechanism was one of the reasons to improve the legislations. Some of the arguments quoted during the discussions were the foreign examplesof succesful PPPs including Portugal during preparaion to Euro 2006.

5 SPORTS GROUNDS AND STADIUMS AS THE CATALYSTS FOR IMPROVEMENT OF BUILT ENVIRONMENT

On of the interesting aspects of the relationships between the Euro 2012 and urban policy are the proposals for the development of stadium immediate environments. The overall positive effects of the development of the sports infrastructure on the city are well documented. Some of the often cited cases include Barcelona, where Olympic Games were integrated into the city wide urban regeneration programme. (Preuss, 2005).

Analysis of the Polish examples indictates that in the case majority of the infrastructural projects supported the long term development strategies for the cities and Euro 2012 chapmionships simply accelerated the process. Development of the stadium and the sites adjacent to it were not so obvious. Comparative look at the Polish examples of Gdansk and Warsaw illustrates that issue of long term, development strategy for these lands is still not resolved. In Warsaw case study one of the main difficulties is caused by the sharing of the competences and responsibilities, especially in relation to developments that are not directly supporting the preparation of Euro 2012. Gdank represents a case study where location of the stadium resulted in increasing support to the adjoining disadvantaged community.

5.1 Warsaw- Stadion City

The debates about the location of the National Stadium took place during the late nineties but they were largely inconclusive. The decision to grant Euro 2012 to Poland and Ukraine gave this discussion a new impetus. Finally, in 2007 the final site selection was made. New site is located on the right bank of Vistula River on the 30 ha site of the former "Stadion Dziesięciolecia". Parallel to the discussion about the National Stadium, other development concepts for the adjoining lands had been discussed.

As a result one of the earliest proposals included a large National Sports Centre with new stadium, sports and exhibition hall, swimming polls, sports accommodation centres as well as small number of commercial uses. Delivery of the initial concepts was delayed due to lack of agreement on funding. National government could not support the development of that magnitude alone. The local government considered he sports centre as a national project.

Situation changed when Poland became a host of UEFA Euro 2012. In September 2007 a governmental, public company – Narodowe Centrum Sportu has been estanblished. One of the main tasks of the company, apart from coordination of the stadium development, was preparation of plans for the environs of the sports arena. Architectural competition for the development of the stadium's environs was held in 2008. Winning team - JEMS Architects and Dawos proposed location of the new commercial development with diversified character with total floorspace of approximately 40,000 sq. m. called "Stadion City". The overall idea of the projects was to locate three large scale venues – stadium, congress centre and modern sports hall in order to create a positive synergy. Concept was enthusiastically received by the consultants from global entertainment company AEG (Anschutz Entertainment Group). Supplementary uses included Polish Football Federation headquarters as well as private offices, administration, residential uses and restaurants. The commercialization of the sports grounds could help to balance the expenditures for the construction of the stadium.

One of the main difficulties of this project was changing political context (new Minister of Sport had been appointed), lack of decisions and lack of coordnation and cooperation on the financing of the project. New Minister of Sport – Jakub Drzewiecki, nominated in November 2007 opposed the idea of provision of the commercial development on the lands owned by the State. In his opinion the lands should have flexible strategy with huge degree of "investment flexibility" rather than detailed masterplan. He also recommended omission of the sports hall from the project. Dismissal of Mr. Drzewiecki in October 2009 did not help the project. Department of Sports refused to fianance any commercial project within the environs grounds of the stadium and for the local government current involvement would create a significant liability. It is more likely that the new development of this area will continue after Euro 2012.

6 GDANSK – ENVIRONS OF THE PGE ARENA AND LETNICA DISTRICT

The site for the stadium was selected in May 2005. In making the final decision some of the important conditions and issues were taken into account such as good access to the public transport, large proportion of the communal land. New site for the stadium had been located on the lands adjacent to Letnica – neglected neighbourhood in the need of regeneration. Plans to build a large stadium casued the increase interested in this neighbourhood. The city officals considered different scenarios for the development.

According to the High Buildings Location Study (SLOW) environs of Letnica caoul accommodate some larger scale developments. The Local Area Development Plan prepared in may 2007 for the stadium and its environs were designated as commercial services with supporting residential uses with permission to byild high rise structures. The concepts about what to do with Letnica evolved into the proposed extensive development – with proposed uses such as outdoor events and concerts. Declaration casued some reaction and started a debate about the future of Letnica. Local architects such as P. Wład-Kowalski and ADS architects from Poznana tried to lobby for the idea of new, modern district. The most probable scenario the land will wait to be developed after 2012.

As mentioned above the decision to locate the development in Letnica was a pretext to start a regenration programme of this once neglected neighbourhood. Local government assigned 75 million Zlotych for the regenration of the neighbourhood which included renovation of the streets and tenement houses, support for the social activites, local neighbourhood scial facilties and open spaces.

7 CONCLUSION

Overall in summary or the long term consequences of UEFA Euro 2012 Championships on legal and organizatinal context of investment it is worth highlighting that the mega event gave reason for a number of significant improvement s to the system. Changes included improvments to the PPP and public tender procedures. These legal acts, improved recently, will have a positive effect on the pro-development urban policy in the city.

The other important change is the debut of the SPVs as the new tool in urban development. It is the first time that such a mechanism is deployed by the public sector. Due to change in legislation, some of these agencies may still function after 31 of December 2010, opening the opportunities for privatization of some of the resources or introduction of new forms of private or quasi-public mechanisms of management.

Euro finally accelerated the delivery of the technical infrastructure too. The side effect of theis intensive development strategiy is that local governments are increasingly limited by their liabilities, caused by the investment. Situation of Poland is more difficult than its Western counterparts since not a single major Polish stadium was built with a help of private sector. It means that the local governments may be forced to seek for other sources fiannacing to meet their liabilities.

Finally Euro 2012 indicates quite diversified level of involvement in management of the urban growth in conjunction with local urban policy. Development of the stadiums is seen as a technical exercise whilst the lands in close vicinity to the stadion are considered as a long term development potential. No operational plans are made to harness this opportunity. What Polish cities are lacking is the long term strategy for the development of the new disticts on the basis of new facilites. Sometimes the program to improve the district can be stalled due to problems with communication between public partners or crisis in leadership as it was illustrated in Warsaw case study.

1 ABSTRACT

Public services should 'live' in public facilities allocations. According to this, one must fit into the other; in the same way as citizens should find an answer in the residential park offer or production activities seek their location in the industrial areas.

This high level of engagement needed is not produced. Services and facilities coexist in an historical isolation.

In addition to this, while services are provided by administration, facilities are at proposal of the town plans. In this context, how can they keep a good relationship? How planning guarantees enough land to allocate public services?

Of the great range and variety of public services, some of them are recognized in the countries constitutional texts as essential or universal citizen's rights. All State Main Texts of different European Nations protect the right of their citizens to enjoy -at least- a good public education, quality in provision of health services and enough offer in assistance to persons. These services, which could be labeled as 'public basics', are widespread respected and unquestioned, thus an acceptable level must be provided by administrations. This minimum threshold in basic public services should be understood as a common European level, in order to give a reference point to governments for the provision of public services.

Basic public services are strictly connected to people because of their essential and universal nature. Services, whose necessity remains unmodified although race, culture, education, nationality, etc. of users' changes. Their universal nature allows the possibility to express them in values per capita, so indicators are possible and needed.

Same thing with facilities; there is a minimum amount of basic public facilities that must be preserved and protected, according to the constitutional texts of European Countries.

The aim of the ongoing research is to obtain indicators for basic public services and basic public facilities, all expressed in values per capita, which will enable both subjects to be viewed in relation to each other in order to discover if they work together.

A methodology for the equivalence of service and facility indicators will be also obtained. The final step would be the production of 'basic recommended values' as European Reference Indicators for Public Facilities and Services which gives the name to the research.

2 SCIENTIFIC CONCEPTS OF THE RESEARCH

Today's Europe must deal with important and structural challenges: the rapid globalization, the climate change or the progressive ageing of its population, to stat just a few significant ones. In addition, the present economic crisis has added even more pressure to these already complex issues.
The "Lisbon Strategy for Growth and Job, towards a green and innovative economy" addresses these challenges with goals such as stimulating growth and creating more and better jobs, while making the economy greener and innovative.
The economic downturn has stopped labour market growing and turned the Agenda measures into more fiscal actions, believing on stimulation of private parties as the most effective way to keep people at work. Parallel to these 'emergency' economic solutions, big investment efforts have been made to maintain Lisbon Strategy's goals concerning infrastructures, research and innovation.
An updated strategy for Europe is needed, a new agenda capable of performing a complete recovery from the crisis. Promptly, the EU 2020 strategy is under construction. First available agenda drafts emphasize the idea of learning and profiting from the current crisis in a way that leads us to a reinvent economy with high

standards of sustainability for both social and natural resources. Innovation and knowledge are the basis to build this new economy, hand in hand with an EU renewed society.

To the construction of this new European scenario, we, as investigators, must contribute fully conscious of the extreme efficiency required, from now on, to manage social and economic resources.

The current research develops a complete methodology on how to make European public social infrastructure more efficient –which means, investing less with better results- thanks to a new integrated vision of public services in such public facilities.

Innovations in economic aspects must not forget public investment. Enhancing the administration's level of investment in general infrastructure it's mandatory -despite of the crisis itself- in order to face the negative social effects brought about by the economic downturn.

Recent exercises and efforts, on behalf of the administration, to re-launch private economy, introducing innovative mechanisms in the stagnant –even recessive– markets, must be matched with there on public version.

Research and innovation policies, concerning the service sector, must be introduced not only fully aware of the market's real dimension, but also conscious of the real social needs. So far, service's provision has been designed form the supplier's –public or private- point of view, not from the receiver's –citizens- needs.

The current European 'hands-on' managing economic and social efficiency implies taking notice of citizens updated needs when providing social goods (mainly services) in social infrastructures (facilities as service's 'containers').

As private actors do with their business, administration must rethink its products and public realm management, as a private company at the edge of its economic sustainability, would do.

The needed efficiency in public goods delivery and social infrastructures will come from a new vision which integrates both, in a way that service's market dimension matches facility's built stock.

This completely new vision is the key target of the ongoing research. Focusing on the Lisbon strategy measure of social sustainability, it will seek for efficiency on the public side, for both services and facilities. This implies a previous understanding that a minimum common EU level of welfare is the basis for a European social sustainability.

With this aim, standards (planning indicators) are proposed as the most efficient way to illustrate levels of social and economical sustainability as well as to put into practice monitoring processes.

The research will demonstrate, with indicators and from different countries, the importance of public facilities and service's joint program and planning. This is the way to ensure a real and efficient administration contribution to the economic and social sustainability goals of the Lisbon 2020 strategies.

3 TECHNICAL CONCEPTS OF THE RESEARCH

Public services should 'live' in public facilities allocations. According to this, one must fit into the other, the same way as citizens should find an answer in the residential stock offer or productive activities seek their location in the industrial areas. If the described necessary matching don not exist, problems arise. For instance, taking residential as example, homeless people or, conversely, over-occupied homes are evident socioeconomic problems of weak social groups, while, in other urban areas, residential stock is empty.

In the industrial world, company's needs sometimes can't find a location in the initially intended area. As a difference with residential stock, other causes exist, apart from the economic ones, which promote companies delocalization: legal possibilities of countries, bonuses or extra conditions offered by governments, etc.

As for services, something similar happens but with the difference that public offer exists in this segment of activity. The coexistence of public and private offer is something exclusive to the tertiary or services sector. The sole exception, found in the residential sector, being the public housing experiences started in the 30s in some European countries, as a social answer to post World Wars destruction scenarios. Although the promotion of social housing increases day by day, it has turned into a public/private co-payment, far away from the quoted figures fully financed by governments.

The service sector includes the public services offer -necessarily located in public sites- and the private one (which corresponds strictly to the tertiary sector), exclusively allocated in private plots and buildings. As a primary explanation of the public-private dual offer we can say that, in general, where the public offer doesn't arrive, the private one does, understanding the lack of the public sector as a business opportunity for the private one. Also true is that, apart from covering this public services 'gaps' (normally concerned with 'new services' related to 'new social needs'), there are -in some services- a duplicity of offers explained by some improvements introduced by the private sector. If the coverage of 'gaps' is related to quantity, the dual

offer is related mainly to quality and innovation. Here, the private offer an alternative to the obsolete, poor, or badly maintained services, public provided, which do not satisfy some or all citizens.
This strong relation between public-private services hides important dangers. In public services provision, administration (normally local governments), develops a social function, guaranteeing -at least- the essential services, the basis of the welfare state. Starting from the most basic ones -related to nets- such as electricity, water, gas, etc. to others -nodal-, such as schools, sport fields, hospitals and so on.
Of the wide range and variety of public services, some are recognized in the different country's constitutional texts as essential or universal citizen's rights. All State Main Texts of different European Nations protect the right of their citizens to enjoy, at least, a good public education, quality in provision of health services and enough provision of assistance to persons. These services, which could be tagged as 'public basics', are widespread, respected and unquestioned, thus an acceptable level must be provided by administrations. This minimum threshold in basic public services should be understood as a common European level, in order to give governments a reference point for the provision of public services.

Basic public services are closely related to people, due to their essential and universal nature, witch remains unmodified despite race, culture, education, nationality, etc of there users. Their universal nature allows the possibility to express them in values per capita, so indicators are possible and needed.

As previously stated, public services are necessarily located in public plots and buildings, which are commonly called public facilities. Thus, production of public social infrastructure (facilities) must fit/match the public services provision, especially for the described basic ones. For example, educational services need to find a location solution in public plots classified as educational, otherwise administration will need to spend additional money to obtain the necessary plots, an extra cost that sometimes is not possible and will impede its construction. When governments don't have such extra money, private promoters appear with the aim of building it, on sites designated as private facilities. It must be said that private offer is necessary and healthy, as citizens want to choose, especially the ones that can pay more.

But there is a minimum amount of basic public services that must be preserved and protected, according to the constitutional texts of European countries. If services must fit in basic public facilities previously obtained, thus facility indicators are also needed.

The aim of the research is to obtain indicators for basic public services and correspondent public facilities, all expressed in values per capita, which will enable both subjects to be viewed in relation to each other,

thus discovering if, together, they work out correctly. A methodology for the equivalence of service and facility indicators, to compare results in different consortium countries, will also be obtained. The final step of the research would be the production of basic recommended values, as European reference indicators for public facilities' planning and services' programming.

4 RESEARCH BEYOND THE STATE-OF-THE-ART

As it will de showed public facilities and public services can both be found as research objects but with limited or inexistent relation between them. The research will break down this unnecessary separation. Public services take place at public facilities gaining this desirable fitting even more importance when referring to the basic service categories, health, education and assistance to persons.

Results of research projects, indicators production and scientific publications on similar works –at national and international levels– are here described in order to better understand and situate de relevance of the present research.

4.1 Research Projects

To begin with, we refer to the projects of the Seventh Framework Programme[1], under EUROSTAT host, and also to the ones subject to the SERVPPIN[2] project of the 'European Association for research on services.

European Projects, presently in progress, focusing on different aspects related to services have been found. For instance, the project Contribution of public and private services to European growth and welfare, and the

[1] http://epp.eurostat.ec.europa.eu/portal/page/portal/research_methodology/research/seventh_framework/projects_and_links
[2] http://www.reser.net/The-SERVPPIN-project_a389.html

role of public-private innovation networks[3] which analyzes the segregation between public and private services. The project focus on public-private innovation networks as an important organizational model to develop, produce and deliver new and improved services, with positive impacts on growth and contributions to welfare. The research consists in an in-depth analysis of case studies covering major services such as health, transport and knowledge intensive services.

Another project concerned with the preservation and improvement of welfare is Globalization, investment, and services trade[4]. It also aims to generate tools for policy-makers and businesses in Europe; instruments that will be produced by a team of European researchers addressing international trade and Foreign Direct Investment (FDI) in the service sectors. There main objective is to integrate this network in the communitarian policies, in such a way that makes it possible to change the old management of the service sector with non-tradable outputs.

On the other hand, on the subject of social infrastructures (or facilities) interesting projects could also be found, but still not related to services contained in them. Here, the Preparatory phase project for a major upgrade of the Council of European Social Science data archives (CESSDA) [5] must be highlighted.

As a central issue, the project aims to establish a European Research Observatory for the Humanities and Social Sciences (EROHS), to be built upon the existing data and resources which, systematically organized, will promote synergy and coherence. Thus, access to the existing European and national data will be more efficient and effective, structuring and linking data resources already available. In addition to this, existing data -indicators and standards- will be improved and their documentation exhaustively developed, to enhance scientific quality and interoperability potential.

This interesting project, though concerned with the development of new indicators (especially in less developed countries) and with improved access to the existing ones (mainly for Northern European countries, already data provided), focuses only on the strict sense of ‘demographic and cultural’ data,

provided by the administrative census of museums, collections, libraries, linguistic corpora and citation indexes. Therefore, information and data regarding health, education and assistance to persons is excluded from the project.

The project is framed in the call for the ESFRI Roadmap, which identifies new Research Infrastructure (RI) of pan-European interest, corresponding to the long term needs of the European research communities, covering all scientific areas, regardless of possible location. The ESFRI roadmap is an interesting on-going process; it will be periodically updated and its subsequent revisions will be considered by the different Member states, as well as by the European Commission, to better define priority projects to be supported at national and community level.

Another project found was Research infrastructures and their structural dimension within the European research area[6], based on the Lisbon Strategy, whose initial aim was to make the EU “the most dynamic and competitive knowledge-based economy in the world, capable of sustainable economic growth with more and better jobs and greater social cohesion, and respect for the environment by 2010" (Lisbon, 2000). The project (a conference) aims to clarify the challenges and opportunities, at regional, national, or international levels, which could be related to the development of research infrastructures (understood as ‘tools of research’) of pan-European character (including the e-infrastructure).

It also takes into account the 2004 review of Lisbon's objectives that enforce the initial strategy, giving more impetus to growth and employment, in hand with the promotion of social/ environmental objectives and highlighting the contribution of such Infrastructures (e.g. impacts on industry, sustainable development, employment, etc.). The main goal is to produce recommendations to improve the financial engineering of research infrastructures, for their construction and sustainable operation. As opposed to the previously discussed projects, this one establishes a relationship between data services and the supporter facility, but

[3] *ServPPIN* (SSH-2007-1.2-02: The implications of developments in the *service* economy for the European economy. Project start date: 2008-02-01)

[5] *CESSDA-PPP* (INFRA-2007-2.2-01 Preparatory phase for the projects in the 2006 ESFRI Roadmap. Project start date: 2008-01-01)
[6] *INFRASTRUCTURE-ERA* (7th FWP- INFRA Research Infrastructures. Project Start date: 2007-12-01)

from the specific perspective of construction and sustainable building work. This approach, although interesting, is far from the viewpoint sought in the ongoing research.

Another project, European social survey infrastructure preparatory phase[7], which participates in the same call, also addresses the production of social infrastructure (facilities) indicators but, like the others, without regarding the connection to the services located within. The project translates the results of the European Social Survey into updated data and a sustainable research infrastructure. As all projects included in the call INFRA-2007, research infrastructures should be understood as the so called 'research tools', like statistics, indicators, standards, etc.

The European Social Survey (ESS), together with the European Value Study, the International Social Survey Program, the Luxembourg Income, the Employment Study, the European Advisory Group on Language Engineering Standards and the European Social Science Data Archives (CESSDA), conform European programmes and institutions producers of research infrastructure, focused on cultural and population aspects, thus there is a gap in indicators related to health, educational and assistance facilities available to people.

The current research will cover this lack of joint indicators for both facilities and services, focused on the basic categories (health, education and assistance to persons). As previously explained this is the main goal, as well as evaluating their degree of correspondence with each planning system. Unique reference indicators for facility and services matching will be provided, which could be used by EU members as recommendations, attending to some adjustments according to each country's planning system and power structure. The international nature of the project permits the extension of the resulting indicators to non-EU countries.

Examining European research projects illustrates the non-integrated work with services and facilities and the greater distance between indicators. The existence of data standards for some facilities, mainly the ones related to culture, has also been shown. As for services, the listed projects do not show the existence of such indicators (the main concern being the possibilities that could be offered by public and private networks). But indicators for services exist; as for facilities, they appear only for demographic and cultural fields and never connected with the supporter facility. To find them we have to move to institutions depending on the European Council, UNESCO, OCDE or the UN.

Furthermore, as for facilities, service indicators are not produced for basic categories (health, education and assistance to persons). For these basic services, few indicators, and not fully representative, are listed in the EUROSTAT data service, corresponding to the annual welfare reports that members submit to the EU Commission.

4.2 Data and Entities producing, revising and maintaining it

In reference to services and related to demographic and cultural fields, in particular services such as archives, libraries or museums, different organizations produce reference values for the service design. The International Council on Archives, and specifically the Committee on Descriptive Standards, offers such indicators. The International Federation of Library Associations and Institutions plays the same role for the library service. For museums, the International Council of Museums provides reference service values.

All these values are presented, in an integrated way, at the Council of Europe web page -http://www.coe.int/[8] and some indexes extracted from countries reports are presented at EUROSTAT site - http://epp.eurostat.ec.europa.eu/portal/page/portal/eurostat/home/-.

Social references can be widely consulted at MISSOC the EU's Mutual Information System on Social Protection witch provides detailed, comparable and regularly updated information about national social protection systems -http://ec.europa.eu/social/main.jsp?catId=815&langId=en-.

The International Council on Social Welfare, dedicated to social development and depending on UNESCO, also provides indicators and standards for some social services - http://www.icsw.org/-.

[7] *ESSPREP*. (INFRA-2007-2.2-01, Preparatory phase for the 2006 ESFRI Roadmap projects. Project start date: 2008-02-18)

[8] International Council on Archives -http://www.ica.org/; Committee on Descriptive Standards - http://www.icacds.org.uk/eng/home.htm; International Federation of Library Associations and Institutions -http://www.ifla.org/; International Council of Museums -http://icom.museum/

Similar information can be found for sport services, as the International Council of Sports Science and Physical Education and the Council of Europe, both founded on the principles described in the Letter of Sport, produce indicators that can be used by administrations for sport services plan and provision - http://www.icsspe.org/-.

But once again, for basic services such as education, health and assistance to persons, specific organizations that produce indicators cannot be found, we must to refer to indexes appearing at EUROSTAT.

4.3 Evidence of Data indicators and common actions need

4.3.1 About Education

The need for more education data, indicators and common actions is shown by the European Commission when launching Council resolutions working on actions such as:

- Creating White Papers like the 'Teaching and learning towards the learning society`.
- Promoting works on quality like the Centre for Educational Research and Innovation (CERI).
- Taking indicator's initiatives such as the 'International Indicators of Educational Systems (INES)' or the 'Evaluation of Educational Achievement (IEA)'.
- Promoting European cooperation in matters as the 'Into the new millennium', developing new working procedures in the education and training field.
- Supporting associations working on transparent quality assurance systems, like the 'European Association for Quality Assurance in Higher Education (ENQA)', the 'European University Association (EUA)', the 'European Association for Institutions of Higher Education (EURASHE)' or the 'National Unions of Students in Europe (ESIB)'
- Supporting the European Centre for the Development of Vocational Training
- Developing European programmes such as: 'Action programme on education'[9];; 'Programme of pilot projects for the improvement of the transition from school to working life'; 'Erasmus'; 'Comett'; or 'Youth for Europe (YES)'
- Also supporting European Networks such as the (EURIDYCE): Education Information Network in the European Community.

These initiatives can be viewed in their original context of Council Conclusions or Council Resolutions in the following extracts:

Council Conclusions of 22 September 1997[10] on the communication concerning the White Paper 'Teaching and learning towards the learning society[11].

Council Conclusions of 16 December 1997[12], on the evaluation of quality in school education, having regard to Article 126 of the Treaty establishing the European Community.

Council Resolution of 17 December 1999[13] concerning 'Into the new millennium', developing new working procedures for European cooperation in the field of education and training

Notices that that the development of a Europe of knowledge and the promotion of lifelong learning both have become shared overall objectives, as an outcome of the Treaty of Amsterdam as well as the EU's Agenda 2000 document. Both resulted in an increase in the importance placed on education in skill and information-related policies, including those which contribute to economic competitiveness and employment in the European Union.

Recommendation of the European Parliament and of the Council of 15 February 2006[14] on further European cooperation on quality assurance in higher education.

[9] 9 February 1976
[10] 31997Y1004
[11] 97/C 303/04
[12] 31998Y0103
[13] 32000Y0112
[14] 32006H0143

Recommends that member states encourage representatives of national authorities, the higher education sector and quality assurance and accreditation agencies, together with social partners, to set up a "European Register of Quality Assurance Agencies" based on national review and to define the conditions for registration as well as the rules for management of the register.

4.3.2 About Education health and assistance to persons

Data pertaining to health and assistance to persons on EUROSTAT is less extensive. The need for more information (statistics, indicators, etc.) for European countries is also present at the European Council Resolutions and Conclusions, trough initiatives similar to the ones for education services:

- European Cooperation on health and nutrition, adopting the 'Programme of Community action in the field of public health (2003-2008).
- Cooperation with WHO (programmes and projects administered by the United Nations), OECD ('System of Health Accounts and collection of data not covered by the Community Statistical Programme'), ECDC ('European Centre for Disease Prevention and Control'), promoting patient safety and health services quality by helping to develop 'European cooperation and collaboration between competent authorities and relevant stakeholders'; national statistical authorities cooperation in the implementation and further expansion of the 'System of Health Accounts in the EU' (in cooperation with the OECD and the WHO).
- European common requirements for the integration of health protection requirements in Community policies
- European common terminology, ensuring health protection in all Community policies and activities
- European promotion of Studies for mental health
- Indicators development through documents such as: 'First phase set of EU health indicators', 'Health Indicators (ECHI)', 'Healthy Life Years Indicator by socioeconomic categories using the standard EU methodology' or 'Healthy Life Years Indicator'
- White papers like'White Paper on nutrition and physical activity' and the 'Report on Contributions to the Green Paper´.

These initiatives can be viewed in their original context in the following extracts:

Council Resolution of 20 December 1995[15], on the integration of health protection requirements in Community policies.

Council resolution of 18 November 1999[16], on the promotion of mental health.

Council Resolution of 2 June 1994[17], on the framework for Community action in the field of public health.

Recalls that emphasis should be done on the encouragement of enhanced cooperation between Member States and coordination of their activities in liaison with the Commission. Previously on 1 December 1993 the Commission forwarded to the Council a communication on the framework for action in the field of public health in the light of the entry into force of the Treaty on European Union.

Council resolution of 18 November 1999[18], on ensuring health protection in all Community policies and activities.

Council Resolution of 14 December 2000[19], on health and nutrition.

Invites the Commission to continue to cooperate with the relevant international organisations, in particular the WHO, to ensure effective coordination of activities and avoid any duplication.

Decision 1786/2002/EC of the European Parliament and of the Council of 23 September 2002[20], adopting a programme of Community action in the field of public health (2003-2008).

[15] 31995Y1230
[16] 32000Y0324
[17] 31994Y0617
[18] 32000Y0324
[19] 32001Y0123
[20] 32002D1786

Stats that cooperation with third countries and the competent international organisations in the sphere of health, such as the WHO, the Council of Europe and the OECD, should be fostered, not only in the field of collecting and analysing data (including indicators) but also in the field of cross-sector health promotion, in order to ensure cost effectiveness, avoid overlapping of activities and programmes and enforce synergy and interaction.

Commission Decision of 25 February 2004[21], adopting the work plan for 2004 for the implementation of the programme of Community action in the field of public health (2003 to 2008).

Commission Decision of 10 February 2006[22], adopting the work plan for 2006 for the implementation of the programme of Community action in the field of public health (2003-2008).

Commission Decision of 12 February 2007[23], adopting the work plan for 2007 for implementation of the programme of Community action in the field of public health (2003-2008).

4.4 An overview from scientific publications

Regarding scientific publication, almost the same absence of relation between public facilities and public services working within is revelled[24], with the exception of a single work with quite similar approaches.

Nevertheless all articles, once again, remark that issues related with public facilities and public services governance are currently on the political agenda.

Concerning 'public service' provision, in the article "Municipal Service Provision Choices within a Metropolitan Area"[25] the authors investigate the decision of municipal governments to out source the provision of public services during the 1980s and 1990s. It extends previous empirical work on outsourcing by distinguishing the type of outsourcing used (e.g., public, private, or other types of providers). Institutional characteristics and fiscal stress are found to play an important role in explaining service choices. It indicates that outsourcing was more common for poor cities than for wealthier ones (as it had already been said in other research works quoted earlier) with the former often relying on government agencies and the latter opting for privatization. Still no reference to the facilities that support these services is made.

Another reference on the subject of public services provision, either by public or private ownership is "Building and managing facilities for public services"[26] which adds "the desirability of bundling the building and management operations, (…) whether it is optimal to allocate ownership to the public or the private sector". Modelling alternative institutional arrangements for building and managing facilities for provision of public services, including the use of the Private Finance Initiative (PFI), explores the effects on innovative investment activity by providers. It also examines how the case for PFI is affected by the (voluntary or automatic) transfer of ownership from the private to the public sector when the contract expires. Asset specificity and service-demand risk play critical roles.

Research on 'public facilities' has been more plentiful, but still with a rather different approach, more concerned with size and the optimal location. As the article "Welfare analysis of the number and locations of local public facilities"[27] witch develops a model with a finite number of households and congestible local public goods where the level of provision, the number of facilities and their locations are all endogenously determined. Proving that an equal-treatment identical-provision second-best optimum exists, where all

households are required to reach the same utility level, the provision of local public good is required to be the same at all facilities, and all facilities must serve the same number of consumers. Such an optimal public facility configuration may be concentrated (single site) or dispersed (multiple sites), depending on congestability, commuting cost and household preference parameters.

Still on this subject, the "Public Facilities Planning"[28] book it's a reference with a different angle, also taken into account by the research, addressed from the planning field. It brings together a careful selection of the major works in planning relate to the provision of public facilities - such as recreation grounds, parks and sports arenas. The opening sections present classic, theoretic papers that lay both the general and the specific foundations for why some facilities are treated outside of the market. Key topics such as institutional issues, the role of the private sector, and the assessment and evaluation of public facilities planning and financing are then examined. Finally, the volume looks at some of the more novel approaches that are emerging in the provision of public facilities, and concludes with a selection of case-studies that demonstrate the application of a set of planning approaches.

As for indicator issues on local government[29], "Identifying barriers to the application of standardized performance indicators in local government" exposes the experience of local governments in many countries who are implementing administrative reforms within the framework of New Public Management (NPM) in order to improve the quality and productivity of public services. The use of performance indicators and benchmarking facilitates evaluation of efficiency regarding the provision of

such services and favours the acquisition of better practices. The problems that may arise in the introduction of performance indicators in local government mainly concern the consensual design and standardization of indicators for various entities, the method to be used for calculations and the selection of analytical criteria to be applied to the values obtained. In this article, we identify obstacles that may be encountered in achieving a standardized definition of performance indicators within local government and, on the basis of learning from the practical experience of several large city councils in Spain, formulate strategies to resolve these problems, taking note of the viability and real efficacy of the solutions adopted.

Finally, it must be pointed out similarities between the research and the "Examination of floor area ratio in residential district in terms of the service level of public facilities – An example of Hu-Wei-Liao readjustment area in Tainan City"[30] research, for it's approach to the need for standards, or ratio, and it's relation with planning development

As it also remarks "A lot of articles have discussed the related factors in developing floor area ratio, but there is no model that includes the service level of public facilities and floor area ratio at once". The starting point for this research was the consciousness that the population and various economic activities in Taiwan have concentrated in cities and that in the past, the uses of land and buildings were primarily controlled by limiting the building coverage ratio and building height. Therefore, there were some problems in the areas with high-degree urbanization, including the overuse of lands, the excessive concentration of population, the significant lack of public facilities, etc. In 1992, the government enforced a law, which provided counties/cities with two options: accepting the standard floor area ratio, or developing detail plan on their own. The control of floor area ratio in Taiwan has existed for about seven years, and the problems above have been partially solved in some places. But the control took into consideration only the largest area of buildings, not the base's impact on the environment, the sufficiency of public facilities around the base, the mixture of land use, and so on. And the plan was not based on local requirements, so it has led to new challenges, such as the space development and urban development. First of all, this study will apply gravity model to evaluate the probability of public facilities service usage. And its result can be used to calculate the occupant load and influenced range of the public facilities. At the same time, the result can be applied to analyze the maximum of land development and to set up the most suitable scale of the floor area ratio. This study will explore the questions of floor area ratio control and urban planning development. Through these items, such as the probability, influenced range and occupant load of the public facilities service, it will set

up a model for the service level of public facilities. The result of the model can be a reference to the draft of floor area ratio.

5 EVIDENCE

To sum it all up, it can be said that theoretical indicators in services and facilities exist, but in a non-integrated way. These standards/indicators mainly appear in cultural and demographical fields. For basic services we must refer to indicators coming from specific Council initiatives that partially cover the areas of education, health and assistance to persons. Basic facilities have a less promising scenario: no indicators exist, other than those for facilities relating to cultural aspects.

The integrated production of indicators for services and facilities launched by the research will help to cover the gaps described. Production that will add new value since information will be obtained from the analysis of existing urban areas, not from theoretical or ideal values. The contrast between the announced theoretical values with those coming from the 'city calculation' will provide extremely interesting information.

Another relevant step of the research will be a second contrast between the existing facilities and services and the ones planned - plan vs real city - revealing inadequacies at both levels: plan/services and plan/facilities.

Ongoing research aims to obtain common European references in the provision of services in facilities, independently of the social model of each country, contributing, at the same time, for the vital undertaking witch represents the extension of the EU to new members.

The research converges in what is intended by the Club of Rome, in their ongoing project Identifying strategic research directions on network and service infrastructures under the hypothesis of a disruptive paradigm concerning global societal developments (PARADISO) . This aims to identify strategic research directions on network and service infrastructures in the hypothesis of a disruptive paradigm concerning global social developments. This possible paradigm shift, which more and more analysts are evoking worldwide, is based on the vision that, in order to avoid major worldwide crises, all countries (developed, emerging, and developing ones) will need to agree, sooner or later, on an alternative way forward, and make their social development models converge.

The EU is, undoubtedly, the world's best placed power to proactively promote this new concept of progress, based on revised social, environmental and economic objectives: true sustainable development, more sustainable economic growth, more equally shared resources, and, as the final goal, the well-being of people around the world.

To this we will add the research on facilities and services needed to support these new objectives, and more precisely the service's infrastructure network to be developed.

1 ABSTRACT

Plan evaluation is generally considered as a problematic field of research. There is no systematic evaluation of regional plans in Germany. With regard to settlement development regulation this paper presents an ex-post-evaluation approach for regional plans. Based on this methodical approach, results of an evaluation of two regional plans are shown.

2 EINLEITUNG

Zwar gilt die Evaluation eines Plans schon immer als integraler Bestandteil komplexer Planungsprozesse (Alexander 2006; Eggers 2006), in Deutschland werden aber in der Regel Regionalpläne keiner Evaluation unterzogen (Kühn 2005, S. 40; Hübler 2002, S. 12). Als Planevaluation wird in diesem Beitrag eine auf empirische Methoden gestützte Abschätzung der Wirksamkeit bzw. des Erfolgs eines Regionalplans sowie einzelner regionalplanerischer Instrumente bezeichnet. Soll nur der Zielerreichungsgrad ermittelt werden, spricht man von einer Erfolgskontrolle. Wird die Evaluation durchgeführt, um intendierte und nicht-intendierte Wirkungen zu erfassen, handelt es sich um eine Wirkungsanalyse. Abhängig von der gewählten zeitlichen Perspektive können eine vergangenheitsorientierte sowie zukunftsorientierte Grundrichtung unterschieden werden. Während bei der Ex-Post-Evaluation bereits eingetretene Wirkungen und Effekte schon länger in Kraft befindlicher Regionalpläne untersucht werden, zielt die Ex-Ante-Evaluation auf eine Abschätzung wahrscheinlich eintretender Wirkungen eines Regionalplanentwurfs ab.

Der seltene Einsatz von Evaluationen in der Regionalplanungspraxis kann insbesondere auf die erheblichen Schwierigkeiten praktischer Planevaluation zurückgeführt werden (Fürst 2000), da Regionalpläne nicht direkt die Flächennutzung steuern, sondern über den Umweg anderer Planungen und Zulassungsentscheidungen wirken. Weitere Hemmnisse sind der Mangel geeigneter Datengrundlagen zur Messung von Ursache-Wirkungsbeziehungen, unpräzise definierte Ziele oder Festlegungen, die keinen evaluierbaren Charakter aufweisen, die geringe Motivation der Regionalplaner zu einer Wirkungs- und Erfolgskontrolle ihrer Pläne und der Mangel an Vorbildern für Planevaluationen und Erkenntnisdefizite bei Methoden.

In einer Planevaluation müssen beobachtete oder erwartete Veränderungen in der sozialen, ökologischen, wirtschaftlichen, politischen, verkehrlichen und siedlungsräumlichen Umwelt kausal auf einen Regionalplan oder einzelne seiner Instrumente zurückgeführt werden. Es gilt die Evidenz solcher Ursache-Wirkungs-Beziehungen empirisch zu beweisen. Hierzu ist ein kontrollierter Einsatz wissenschaftlicher Evaluationsmethoden notwendig. Ein standardisiertes Methodendesign für die Evaluation von Regionalplänen ist allerdings noch nicht entwickelt und in Frage kommende Methoden und Möglichkeiten ihrer Kombination sind erst in Ansätzen diskutiert (Shefer/Kaess 1990; Talen 1996, S. 80 f.). Dieser Beitrag demonstriert am Beispiel der Steuerung der Siedlungsflächenentwicklung, mit welchen Methoden eine Ex-post-Evaluation der Instrumente von Regionalplänen durchgeführt werden kann. Dargestellt werden die Forschungsergebnisse aus dem Refina-Vorhaben „Entwicklung eines fernerkundungsgestützten Flächenbarometers als Grundlage für ein nachhaltiges Flächenmanagement – Teilvorhaben Evaluation“, das durch das Bundesministerium für Bildung und Forschung (BMBF) gefördert und von 2006 bis 2009 durchgeführt wurde. In Fallstudien für zwei Planungsregionen der Regionalplanung (München und Westsachsen) wurde die Wirksamkeit von Instrumenten der Regionalplanung im Bereich der Siedlungsentwicklung für bereits in Kraft befindliche Regionalpläne gemessen und die Leistungsfähigkeit des eingesetzten Methodenmix systematisch geprüft (Einig et al. 2009).

Der Beitrag konzentriert sich auf die Evaluation regionalplanerischer Instrumente zur Steuerung der Siedlungsentwicklung (Kapitel 3), entwickelt die theoretischen Grundlagen eine Evaluation von Regionalplänen (Kapitel 4), stellt den angewandten Evaluationsansatz vor (Kapitel 5) und präsentiert ausgewählte Ergebnisse der Planevaluation (Kapitel 6).

3 REGIONALPLANERISCHE INSTRUMENTE ZUR STEUERUNG DER SIEDLUNGSFLÄCHENENTWICKLUNG

Im Kontext der Regionalplanung werden Instrumente vorrangig als gestaltende Mittel zur direkten Beeinflussung raumbedeutsamer Vorhaben und Planungen anderer öffentlicher Stellen und zur indirekten Einflussnahme auf die Raumentwicklung verstanden. Regionalpläne definieren zukünftig zu erreichende Ziele und verknüpfen diese mit Instrumenten, um Rechtsfolgen für die Adressaten der Ziele zu setzen, ohne allerdings die Art und Weise der Zielverwirklichung detailliert vorzuschreiben. Dabei ist der Gesamtzusammenhang aller instrumentellen Komponenten eines Regionalplans von Relevanz (Kment 2002a, S. 37). Die Wirkung regionalplanerischer Festlegungen für die Siedlungsentwicklung in einer Region ist zum einen von ihrem rechtlichen Status – ihrer Rechtsnormqualität – abhängig und zum anderen von ihrem Steuerungsmechanismus, d. h. vom Inhalt der Verhaltensvorschrift, die durch eine Festlegung normiert wird.

Pauschal kann man sagen, dass die Steuerungswirkung einer Festlegung zunimmt, je verbindlicher eine Festlegung Verhaltensvorgaben für ihre Adressaten vorgibt. Raumordnungsrechtlich verbindliche Festlegungen der Regionalplanung sind gemäß § 3 Nr. 1 ROG prinzipiell nur Ziele, Grundsätze und sonstige Erfordernisse der Raumordnung. Diese drei Festlegungstypen ziehen unterschiedliche Rechtsfolgen für ihre Adressaten nach sich (Heemeyer 2006; Kment 2002). Ziele der Raumordnung lösen bei ihren Adressaten eine strikte Beachtenspflicht aus, die diese nicht durch Abwägung oder Ermessensausübung überwinden können. Sie stellen die strikteste Form der Verhaltensbindung durch raumordnungsrechtliche Normierung dar. Grundsätze der Raumordnung sind Vorgaben für nachfolgende Abwägungs- oder Ermessensentscheidungen. Sie begründen eine Berücksichtigungspflicht für ihre Adressaten und können daher durch eine gerechte Abwägung durch diese überwunden werden. Ebenfalls eine Berücksichtigungspflicht wird durch sonstige Erfordernisse der Raumordnung (in Aufstellung befindliche Ziele der Raumordnung, Ergebnisse förmlicher landesplanerischer Verfahren, landesplanerische Stellungnahmen) ausgelöst. Die Adressaten werden durch Ziele der Raumordnung aufgrund der zwingenden Beachtenspflicht stärker gebunden, als durch Grundsätze der Raumordnung, die wie ein Optimierungsgebot wirken und von den Adressaten, im Sinne eines „soviel wie möglich“ zu berücksichtigen sind.

Neben der Rechtsnormqualität der Festlegungen eines Regionalplans ist ihre Wirkung vor allem von ihrem endogenen Steuerungsmechanismus abhängig. Ausgehend von ihrem Wirkprinzip werden unterschiedliche Instrumente unterschieden. In der Summe bilden die Instrumente eines Regionalplans einen Instrumentenverbund.

Einige Klassifikationsansätze von Instrumenten, die in Regionalplänen eingesetzt werden, orientieren sich an ihrem inhaltlichen Bezug, d. h. ob sie die Steuerung der Siedlungs-, Freiraum- oder Infrastruktur einer Region bezwecken (Kistenmacher 1991, S. 28):

- Instrumente zur räumlichen Koordination der Siedlungsentwicklung (Zentrale Orte, Achsen, gemeindescharfe Funktionszuweisungen, Vorranggebiete für Siedlungsentwicklung),
- Instrumente zum Freiraum- und Ressourcenschutz und zur Koordination konkurrierender Nutzungen im Freiraum (Grünzüge, Vorrang- und Vorbehaltsgebiete für Natur- und Landschaft, Hochwasserschutz, Windkraftnutzung, Rohstoffabbau, Erholung),
- Instrumente zur räumlichen Steuerung technischer und sozialer Infrastrukturen (Ausstattungskataloge Zentraler Orte, Vorrangstandorte für Einrichtungen und technische Bauten, Vorrang- und Vorbehaltsgebiete für Infrastrukturkorridore).

Neben inhaltlich orientierten Unterscheidungsansätzen hat die Planungsforschung aber auch Instrumenteneinteilungen entsprechend der basalen Wirkungsmechanismen vorgenommen. Die bekannteste Klassifikation unterscheidet positiv- und negativplanerische Instrumente (Einig 2005; Istel 1991; Lendi 1997; Siedentop 2008, S. 115 f.). Negativplanerische Instrumente normieren einen Bestandsschutz für bestehende Flächennutzungen und verbieten Adressaten bestimmte Formen der Flächennutzung und

schließen raumbedeutsame Vorhaben aus, die im Konflikt zu den geschützten Bestandsnutzungen stehen (Lendi 1997, S. 127). Entscheidend ist ihre Negativwirkung (Schulte 1996, S. 71). Negativplanerische Festlegungen weisen eine ummittelbar nutzungssteuernde Wirkung auf (Spannowsky 1997, S. 765). Ein positivplanerisches Instrument hingegen ermöglicht Adressaten eine bestimmte Form der Flächennutzung bzw. legitimiert zu einer Planung eines raumbedeutsamen Vorhabens, das nur durch einen Wandel der Flächennutzung umzusetzen ist (Lendi 1997, S. 127). Die Positivwirkung einer Festlegung im Regionalplan fördert die Durchsetzung der Zielnutzung, führt allerdings nicht automatisch zu einem Anspruch auf bauplanungsrechtliche Zulassung eines entsprechenden Vorhabens (Schulte 1996, S. 72).

In Bezug auf ihr Steuerungsprinzip sind nicht alle positiv- und negativplanerischen Instrumente gleich. Eine mengen- und standortsteuernde Grundwirkung sind zu unterscheiden (Einig 2005, S. 51). Mengensteuernde Instrumente dienen beispielsweise einer Begrenzung des Umfangs der gemeindlichen Neuausweisung von Bauland oder auch der Erhaltung eines Mindestbestandes von Freiraum. Standortsteuernden Instrumenten obliegt die räumliche Lenkung bestimmter Vorhaben und Nutzungen. Im Falle der Baulandentwicklung haben sie entweder die präzise Ausrichtung der kommunalen Bauleitplanung auf raumordnerisch geeignete Standorte oder deren standortgenaue Abwehr zum Ziel.

Zur Steuerung der Siedlungsentwicklung können positiv- wie negativplanerische Instrumente mit einer mengen- oder standortsteuernden Lenkungsform kombiniert werden (vgl. Abb. 1).

	Positivplanerischer Ansatz	**Negativplanerischer Ansatz**
Standortsteuernde Instrumente	Vorranggebiete für Siedlungsentwicklung	Grünzäsuren
Mengensteuernde Instrumente	Gemeindescharfe Kontingente maximal zulässiger Brutto-Neubaulandausweisung	Mindestflächenanteil des Biotopverbundes an Planungsregion

Abb. 1: Regulierungsprinzipien in Raumordnungsplänen, Quelle: Einig 2005, S. 287

Mittels positivplanerischer Instrumente können Raumordnungspläne auf direktem Wege (aktivplanerisch) die Baulandausweisungen der Gemeinden räumlich lenken und in Grenzen auch mengenbezogen steuern. Der Einsatz negativplanerischer raumordnungsrechtlich verbindlicher Festlegungen in Regionalplänen erhöht den Schutzstatus von Freiräumen gegenüber einer baulichen Inanspruchnahme. Eine Ausrichtung baulicher Vorhaben auf jene Standorte, die eine besondere Eignung für bauliche Nutzungen aufweisen, vermögen treffsicher nur positivplanerische Raumordnungsgebiete zu leisten.

Abb. 2: Instrumentenverbund der Fallstudienregionen, Quelle: eigene Darstellung

Obwohl alle Regionalpläne in Form von Zielen oder Grundsätzen der Raumordnung verbindliche negativplanerische Instrumente des Freiraumschutzes ebenso wie positivplanerische Instrumente zur Koordination der Baulandentwicklung der Gemeinden und zur Entwicklung der Siedlungsstruktur einer Region einsetzen, bestehen erhebliche länderspezifische Unterschiede. Die hier untersuchten Instrumentenverbünde der Fallstudienregionen München und Westsachsen sind verhältnismäßig ähnlich ausgebildet. Die Regionalplanung in beiden Ländern zeichnet sich durch einen weitgehenden Verzicht auf positivplanerische Instrumente zur Mengensteuerung der kommunalen Baulandentwicklung aus. In begrenztem Umfang ist eine Mengensteuerung mit Hilfe des Instruments Eigenentwicklung bzw. organische Entwicklung möglich. Es werden vor allem standortsteuernde Instrumente genutzt. Für die kleinräumige

Steuerung der Siedlungsentwicklung sind in beiden Regionen negativplanerische Instrumente von zentraler Bedeutung (Abb. 2).

4 THEORETISCHE GRUNDLAGE DER PLANEVALUATION

Seit den 1990er Jahren gewinnt der Ansatz einer theoriegeleiteten Evaluation an Bedeutung (Weiss 1998; Chen 1990). Die Grundidee theoriebasierter Evaluation besteht darin, von den Wirkungen eines Instruments ein „theoretisches“ bzw. „logisches“ Modell mit Hilfe der wichtigsten Stakeholder zu entwickeln. Ein solches Modell beschreibt die Wirkungszusammenhänge eines Instruments in Bezug auf zentrale Input-, Prozess- und Outcome-Variablen. Eine Wirkungstheorie enthält Annahmen darüber, auf welchem Implementationsweg ein Instrument zu möglichen Effekten führt (Weiss 1998, 55). Das Ziel der Modellbildung ist die Rekonstruktion, warum ein Instrument intendierte Ziele erreicht oder verfehlt und welche Aspekte diese Wirkung erklären können. Eine theoriegeleitete Evaluation folgt den rekonstruierten Wirkungsketten (Brickmayer/Weiss 2000, 408). Zentrales Element einer theoriegestützten Evaluation ist die Integration von Wirkungstheorien in den Evaluationsprozess (Chen 1990, 39). Häufig werden konkurrierende Wirkungstheorien gebildet. Durch intensive Meinungsforschung wird beispielsweise rekonstruiert, wie die Autoren von Regionalplänen die Wirksamkeit ihrer Pläne einschätzen oder es wird die Wirkungswahrnehmung auf Seiten der Adressaten abgebildet. Ergänzt werden die pluralen Sichten der zentralen Stakeholder durch die Einschätzung der Evaluatoren, die ebenfalls Theorien über Wirkungen der untersuchten Instrumente entwickeln.

Die theoriegeleitete Evaluation ist nicht methodengebunden. So können verschiedene qualitative oder quantitative Methoden genutzt werden, solange dies den theoretischen Zwecken dient (Chen 1990, 84).

Bei der Evaluation von Regionalplänen sind das gesetzlich normierte Verhältnis von Regional- zu Kommunalplanung sowie das Anpassungsverhalten der Planadressaten zu beachten. Bestandteile der Wirkungskette sind zunächst der Regionalplan bzw. dessen Instrumente als Programminput sowie die siedlungsräumliche Entwicklung als Effekt. Regionalpläne steuern die Flächennutzung über den Umweg anderer Planungen und Zulassungsentscheidungen. Insofern handelt es sich bei den Regionalplänen um eine "Planung der Planung" (Einig 2003, 2008, S. 25). Direkte Effekte der Flächennutzung bewirken Regionalpläne erst nachdem sie in Bauleit- und Fachplänen weiter konkretisiert wurden und in Entscheidungen von Genehmigungsbehörden über die Zulässigkeit raumbedeutsamer Planungen und Maßnahmen eingeflossen sind (Heemeyer 2006). Voraussetzung für eine Steuerung der Siedlungsentwicklung durch regionalplanerische Festsetzungen ist deren tatsächliche Umsetzung auf Ebene der Kommunalplanung. Auf Grund dieser Mehrebenensteuerung müssen in einer Planevaluation neben indirekten Wirkungen auf die Flächennutzung auch direkte Wirkungen auf Seiten der Planadressaten gemessen werden. In beiden Fällen müssen die Wirkungen kausal auf einen Regionalplan oder einzelne seiner Instrumente zurückgeführt werden können. Im empirischen Beweis der Evidenz solcher Ursache-Wirkungs-Beziehungen besteht die wissenschaftlich schwierigste Herausforderung von Planevaluationen. Gelingt es mittels Indikatoren, auf der Basis qualitativer und quantitativer Daten, einzelne Instrumente als Ursache beobachtbarer Effekte zu identifizieren, kann die Wirksamkeit der unterschiedlichen Instrumentenverbünde ermittelt und vergleichend bewertet werden.

Sehr unterschiedliche Daten sind erforderlich, um den Wirkungspfad eines Regionalplans vollständig zu beobachten. Zuerst werden Planungsdaten für die unterschiedlichen Ebenen des Raumplanungssystems benötigt. Liegen Daten über die Anpassungsreaktionen der Kommunen in Form von Flächennutzungs- und Bebauungsplänen vor, sind die vielfältigen Fachplanungen und die vorhabenbezogenen Genehmigungs- und Zulassungsentscheidungen von Behörden bekannt, lässt sich verhältnismäßig genau beurteilen, ob die Festlegungen eines Regionalplans ausreichend von den direkten Adressaten des Plans berücksichtigt und eingehalten wurden. Ergänzend werden präzise Daten zur Entwicklung von Art und Intensität der Flächennutzung benötigt. Erst die Verfügbarkeit eines verhältnismäßig komplexen Datenkatalogs gestattet es, das Wirkungsspektrum von Regionalplänen in Ansätzen zu beobachten und den Grad des Erfolges eines Plans zu bewerten.

5 METHODE DER INSTRUMENTENBEZOGENEN PLANEVALUATION

Die Forschungsergebnisse belegen, dass geeignete Daten sehr häufig weder in der sachlichen, zeitlichen, noch in der räumlichen Differenziertheit existieren. Beispielsweise liegen nicht für alle Planungsregionen

Raumordnungskataster mit Informationen über alle relevanten raumbedeutsamen Vorhaben vor. Oft sind diese Planungsdaten auch noch nicht in einer digitalen Fassung verfügbar, so dass Verschneidungen des Regionalplans mit den Plänen der Kommunen und der Fachplanungen mittels eines Geographischen Informationssystems nur mit sehr großem Aufwand realisierbar sind. Aufgrund der Datenrestriktionen ist ergänzend eine Thematisierung der Wirkungswahrnehmungen und Erfolgsbewertungen zentraler Akteursgruppen notwendig. In der theoriebasierten Evaluationsforschung ist deshalb eine intensive Einbeziehung relevanter Stakeholder vorgesehen (Donaldson 2007; Leeuw 2003; Vaessen 2006). Um den Verhaltenseffekt von Instrumenten und Plänen besser beurteilen zu können, müssen Meinungen unterschiedlicher Akteure über die Wirkungsweise und den Erfolg von Plänen und Instrumenten rekonstruiert werden. Diese komplexen Untersuchungsschritte verlangen nach dem Einsatz sehr unterschiedlicher sowohl qualitativer als auch quantitativer Methoden der empirischen Sozialforschung. Im Resultat ergab sich ein Evaluationsansatz mit sechs Untersuchungsphasen (Abb. 3).

Abb. 3: Evaluationsansatz, Quelle: eigene Darstellung

Die Basis der Planevaluation bildet die Identifikation verbindlicher Instrumente zur Steuerung der Siedlungsentwicklung in den Fallstudienregionen. Unter Berücksichtigung raumordnungsrechtlicher Vorschriften kann auf Grundlage der textlichen und zeichnerischen Festlegungen der Regionalpläne eine Bewertung der Restriktivität der Instrumente vorgenommen werden (Teilbewertung Plananalyse). Zentrales Element der Ex-Post-Evaluation ist der sogenannte Soll-Ist-Vergleich. In dieser Phase werden die verbindlichen Vorgaben der Regionalpläne mit der realen Raumentwicklungen sowie den Inhalten der kommunalen Bauleitpläne, die als Adressaten der Regionalpläne dessen Festlegungen beachten bzw. berücksichtigen müssen, verglichen. Die Gegenüberstellung basiert auf einer Auswertung amtlicher Statistiken sowie einer quantitativen Analyen von Geodaten der zeichnerischen Festlegungen der Regionalpläne sowie der geplanten (FNP) und bestehenden (ATKIS) baulichen Flächennutzung. Mittels dieser Daten lassen sich Abweichungen von regionalplanerischen Festlegungen identifizieren (Teilbewertung Soll-Ist-Vergleich). Parallel zu den genannten Phasen werden Experteninterviews mit Planungsakteuren auf Landes-, Regional-, Kreis- und Gemeindeebene geführt. Vor dem Hintergrund langjähriger Erfahrungen mit regionalplanerischen Festlegungen erfolgt durch diese Akteure eine Einschätzung der Steuerungswirksamkeit der Planinstrumente. Das über die Gespräche generierte Expertenwissen dient insbesondere als Fundament der Stakeholder-Befragung. Als primäre Adressaten der Regionalpläne nehmen die Kommunen auf Grundlage eines standardisierten Fragebongens eine Bewertung der Steuerungswirkung vor und beziehen insbesondere zur Akzeptanz und zum Reformbedarf der Instrumente Stellung (Teilbewertung Befragung). Die Implementation der Regionalpläne wird in der fünften Phase über eine Auswertung von Stellungnahmen der Regionalplanung zu kommunalen Bauleitplanungen überprüft. In den Stellungnahmen können Konflikte zwischen verbindlichen Festlegungen der Regionalpläne und kommunalen Planungsvorhaben erfasst werden (Teilbewertung Planvollzug). Auf der Grundlage der Ergebnisse dieser Meinungsforschung können Theorien über die Wirkungsweise der untersuchten Instrumente abgeleitet werden. Diese Theorien werden dann mit den Ergebnissen der anderen Methodenblöcke verglichen. Erst aus der Gegenüberstellung von quantitativen Analysen auf der Basis von

amtlicher Statistik und Geodaten, der Vollzugsanalyse sowie den Einschätzungen der Wirkungen und des Steuerungserfolges der Instrumente durch die Stakeholder, kann eine angemessene Abbildung der Wirkungskette von Instrumenten sowie eine Bewertung der Steuerungseffektivität gelingen. Für die abschließende Gesamtbewertung der Steuerungseffektivität der einzelnen Instrumente werden die qualitativen und quantitativen Ergebnisse der Teilbewertungen zusammengefasst. Auch hier hat sich ein qualitativer Bewertungsansatz gegenüber einer quantitativen Vorgehensweise als vorteilhaft erwiesen. Auf Grund vielfältiger Erklärungsansätze für die Begründung der ermittelten Werte muss die Interpretation der Resultate sehr kontextsensibel vorgenommen werden. Nachdem für jedes Instrument eine Gesamtbewertung erfolgt ist, kann der Steuerungsansatz des gesamten Verbundes beurteilt werden. Auch hier kommt ein qualitativer Ansatz zum Einsatz.

6 AUSGEWÄHLTE EVALUATIONSERGEBNISSE

Die Ex-Post-Evaluation der Raumordnungspläne bzw. -instrumente wurde in beiden Fallstudienregionen auf Basis des vorgestellten Evaluationsansatzes durchgeführt. Die Teilbewertung sowie die Gesamtbewertung erfolgte jeweils über fünf Bewertungskategorien: gering, mittel und hoch sowie gering/mittel und mittel/hoch. Da hier nicht für alle untersuchten Instrumente die einzelnen Phasen der Evaluation durchlaufen werden können, werden zunächst die Bewertungsgrundlagen und Teilbewertungen der Evaluation für das Instrument "Regionale Grünzüge" exemplarisch vorgestellt. Im Anschluss erfolgt eine kurze Darstellung der Gesamtbewertung der regionalen Instrumentenverbünde.

6.1 Instrumentenbewertung Regionale Grünzüge

Regionale Grünzüge zählen zu den klassischen multifunktionalen Instrumenten des Freiraumschutzes. Sie sind für die Steuerung der Siedlungsentwicklung unverzichtbar (Domhardt 2005, S. 239). Das Instrument zielt in erster Linie auf den Schutz vor Bebauung und eine Vernetzung schutzwürdiger Freiraumflächen. Bevorzugtes Einsatzgebiet sind Regionen mit hohem Siedlungsdruck.

6.1.1 Plananalyse

In beiden Planungsregionen werden Regionale Grünzüge als standortsteuernde Instrumente genutzt. Sie weisen jeweils die Rechtsqualität eines Ziels der Raumordnung auf und müssen demzufolge von den Kommunen und Fachplanungsträgern strikt beachtet werden. Allerdings wird die Bindungswirkung durch Ausnahmeregelungen eingeschränkt, so dass die Festlegungen durch ihre Regel-Ausnahme-Struktur in keiner der beiden Regionen eine hohe Restriktivität aufweisen. Ausschlaggebend für die Bewertung ist die konkrete Formulierung der Ziele bzw. der Ausnahmen. Während in Westsachsen der Freiraumschutz einen strikten Vorrang besitzt und Ausnahmen auf Investitionen mit Landesbedeutung beschränkt sind, weist der Regionalplan der Region München eine deutlich geringere Regelungsintensität auf. Der Kreis zulässiger Bauten wird durch die Ausnahmeregelung nicht restriktiv eingeschränkt. Aus diesem Grund ist die Restriktivität der Regionalen Grünzüge in Westsachsen höher als in München einzuschätzen. Von der Ausweisung Regionaler Grünzüge ist in beiden Regionen nur ein Teil der Kommunen betroffen.

	Planaussagen		**Bewertung**	
	Rechtsqualität	**Ausnahmeregelung**	**Restriktivität**	**Betroffenheit der Kommunen**
München	Ziel	Ja	Mittel	Mittel
Westsachsen	Ziel	Ja	Mittel/Hoch	Mittel

Abb. 4: Plananalyse, Quelle: eigene Darstellung

6.1.2 Soll-Ist-Vergleich

Unter Nutzung gebietsscharfer Geodaten ist eine quantitative Erfolgskontrolle der Regionalen Grünzüge möglich. Diese bilden neben den Regionalen Grünzügen die geplante (Flächennutzungsplanung) und tatsächliche Flächennutzung (Amtliches topographisch-kartographisches Informationssystem (ATKIS)) ab. Bei der Analyse sind Besonderheiten der regionalplanerischen Ausweisungen zu berücksichtigen. So überlagert die Darstellung der Regionalen Grünzüge im Regionalplan der Region München bewusst Bereiche, die in bestehenden Flächennutzungsplänen bereits als Siedlungsfläche dargestellt werden. Diese Siedlungsgebiete werden im Regionalplan eindeutig aus der Zielfestlegung ausgeklammert und müssen deshalb nicht an die Vorgaben des Regionalplans angepasst werden. Aus diesem Grund ist für die Region München der Anteil der baulich geprägten Flächen ausschlaggebend, der in Regionalen Grünzügen und

gleichzeitig außerhalb der in FNP ausgewiesenen Siedlungsgebiete liegt. Im Ergebnis zeigt sich für die Region Westsachsen eine höhere Anpassung der Realnutzung an die ausgewiesenen Regionalen Grünzüge. Der Anteil baulich geprägter Flächen in den Regionalen Grünzügen fällt in der Region München deutlich größer aus (vgl. Abb. 5). Das Ergebnis ist nicht nur auf den höheren Siedlungsdruck in dieser Region, sondern auch auf die geringere Restriktivität der regionalplanerischen Festlegung zurückzuführen. Offensichtlich werden hier wiederholt Zulassungen von Siedlungsentwicklungen in Grünzügen auf Basis der Ausnahmeregelung erteilt.

Im Hinblick auf den Soll-Ist-Vergleich der Flächennutzungsplanung kann mit den vorliegen Daten für die Region München keine Bewertung vorgenommen werden, da eine Entwicklung der in FNP ausgewiesenen Siedlungsbereiche in den Regionalen Grünzügen nicht abgebildet werden kann. Die vorliegenden Daten spiegeln nur den aktuellen Stand der Flächennutzungsplanung wider. Ob ein Plan bereits vor In-Kraft-Treten des Regionalplans aufgestellt wurde und dementsprechend keine Verletzung der ausgewiesenen Regionalen Grünzüge darstellt kann nicht überprüft werden.

	München	**Westsachsen**
Soll-Ist-Vergleich Realnutzung		
Anteil baulich geprägter Flächen , der in Regionalen Grünzügen liegt	5,2 %	2,1 %

Abb. 5: Ergebnisse des Soll-Ist-Vergleichs, Quelle: eigene Darstellung, Daten: ATKIS

Die Teilbewertung des Soll-Ist-Vergleichs zeigt für die Region München, dass die Entwicklung im mittleren Maße der Festlegung des Regionalplans folgt. Demgegenüber kann für die Region Westsachsen eine hohe Übereinstimmung sowohl im Hinblick auf die Realnutzung als auch auf den Flächennutzungsplan festgestellt werden. Allerdings muss berücksichtigt werden, dass erst wenige Gemeinden der Region Westsachsen überhaupt einen Flächennutzungsplan aufgestellt haben. Für die übrigen Instrumente werden die Untersuchungsergebnisse des Soll-Ist-Vergleichs in Tabelle 3 abgebildet.

6.1.3 Bewertung durch die Kommunen

Eine Einschätzung, ob mittels Regionaler Grünzüge schutzwürdige Freiraumflächen vor eine Bebauung geschützt werden konnten, fällt den meisten Kommunen schwer. Nur rund 50 % der befragten Städte und Gemeinden gaben eine Bewertung ab. Diese Kommunalvertreter halten das Instrument in der Regel für erfolgreich. In der Region München fällt das Urteil insgesamt etwas kritischer aus (vgl. Abb. 6). Darüber hinaus stellen die Regionalen Grünzüge ein weitgehend von den Kommunen akzeptiertes Instrument der Regionalplanung dar, dessen Restriktivität grundsätzlich als angemessen angesehen wird (vgl. Abb. 7). Auffällig ist die relativ heterogene Bewertung in der Region München. Ausschlaggebend für die Forderung nach einer Abschwächung der Restriktivität können insbesondere Konflikte mit Regionalen Grünzügen bei kommunalen Planungen sein. Allerdings erkennen einzelne Kommunen auch die Notwendigkeit, den Freiraum durch restriktivere Festsetzungen und die Einschränkung von Ausnahmeregelungen besser zu schützen. Insgesamt nehmen die Kommunalvertreter eine hohe Zielerreichung, sowie einer geringe Einschränkung der kommunalen Planungshoheit durch Regionale Grünzüge wahr.

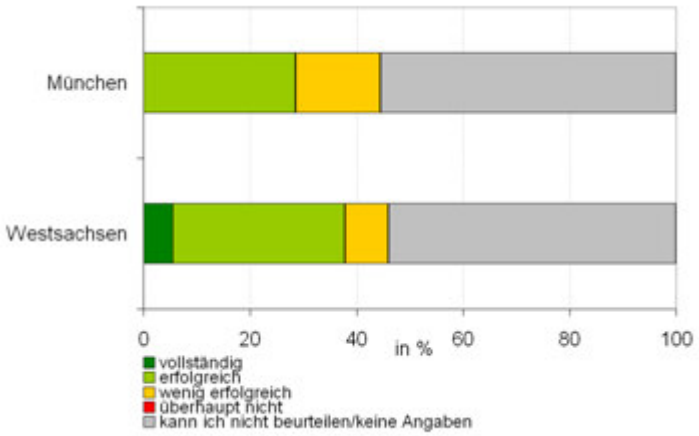

Abb. 6: Zielerreichung der Festlegungen zu Regionalen Grünzügen, Quelle: Kommunalbefragung BBSR 2009

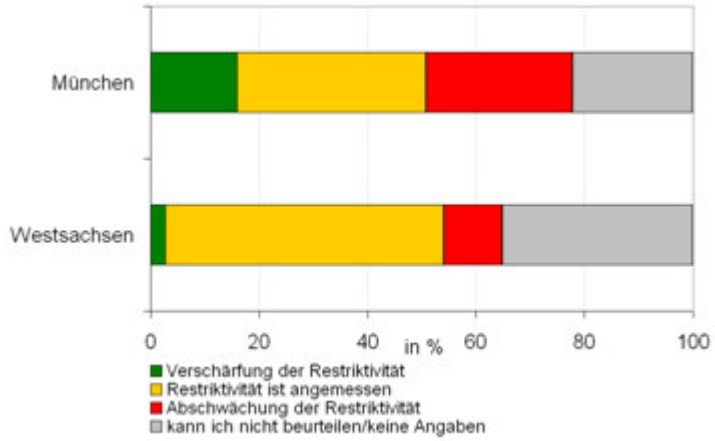

Abb. 7: Restriktivität der Festlegung zu Regionalen Grünzügen, Quelle: Kommunalbefragung BBSR 2009

6.1.4 Vollzugsanalyse

Die Träger der Regionalplanung sind bei allen Flächennutzungsplanverfahren und bei den anzeigepflichtigen Bebauungsplanverfahren als Träger öffentlicher Belange beteiligt. In ihren Stellungnahmen überprüfen sie, ob ein raumbedeutsames Vorhaben im Konflikt zu verbindlichen Festlegungen eines Regionalplans steht. Erfolgt eine negative Stellungnahme, wird dem kommunalen Planungsträger sowie der verantwortlichen Genehmigungsstelle signalisiert, dass ein Konflikt mit einer verbindlichen Vorgabe des Regionalplans besteht. Sind Ziele der Raumordnung betroffen und kann der Kommune nachgewiesen werden, dass weder eine erforderliche Beachtung noch eine Anpassung an den Zielinhalt stattgefunden hat, ist eine anschließende Genehmigung des Plans nicht möglich. Die Planung muss dann grundlegend überarbeitet werden.

Im Zuge des Stellungnahmenverfahrens bei Flächennutzungsplanungen bedingen Regionale Grünzüge relativ selten Konflikte zwischen Kommunen und Regionalplanung (vgl. Abb. 8). Das Instrument führt in vier (München) bzw. zwei (Westsachsen) Verfahren zur Ablehnung einer kommunalen Planung aufgrund bestehender Abweichungen. Da die Grundgesamtheit der Verfahren in den Fallstudienregionen erheblich differiert, ist eine instrumentenbezogene Vollzugsanalyse nur auf Grundlage relativer Werte sinnvoll. Die Differenzen sind auf abweichende Untersuchungszeiträume, eine unterschiedliche Gemeindeanzahl je Region sowie den Umstand, dass für einige Gemeinden in der Region Westsachsen noch kein Flächennutzungsplan vorliegt, zurückzuführen. Als Basis für eine vergleichende Bewertung aller Instrumente wurden für die Analyse folgende Schwellenwerte definiert. Die Konflikthäufigkeit wird als gering bewertet, wenn ein Instrument keine Konflikte verursacht hat. Treten Konflikte mit einem Instrument in weniger als 3 % aller Verfahren auf, so liegt eine mittlere Konflikthäufigkeit, bei höheren Anteilen eine hohe Konflikthäufigkeit vor. Demnach ist in der Region München von einer mittleren und in der Region Westsachsen, trotz der geringen absoluten Konfliktzahl, sogar von einer hohen Konflikthäufigkeit auszugehen. Der Wert verdeutlicht die Bedeutung des Instruments in der Region Westsachsen. Das Ergebnis belegt, dass das Instrument von der Regionalplanung aktiv zur Steuerung der Siedlungsflächenentwicklung herangezogen wird.

	Anzahl der Konflikte	**Anteil an allen Verfahren**	**Anzahl der Verfahren**	**Untersuchungs-zeitraum**
München	4	1,0 %	396	2005 - 2007
Westsachsen	2	3,3 %	61	2001 - 2007

Abb. 8: Konfliktfälle in FNP-Verfahren, Quelle: eigene Darstellung

6.1.5 Gesamtbewertung Regionale Grünzüge

Die zusammenfassende Bewertung bescheinigt der Region München eine mittlere und der Region Westsachsen eine mittel/hohe Steuerungseffektivität für das des Instrument der Regionalen Grünzugs. Ausschlaggebend für diese Einschätzung sind die höhere Restriktivität sowie der positivere Soll-Ist-Vergleich in der Region Westsachsen.

	Plananalyse		Soll-Ist-Vergleich	Kommunalbefragung		Plan-vollzug	Bewertung
	Restrik-tivität	Betroffenheit der Kommunen	Entwicklung folgt dem Plan	Ziel-erreichung	Einschränkung Planungshoheit	Konflikt-häufigkeit	Steuerungs-effektivität
München	mittel	mittel	mittel	hoch	gering	mittel	mittel
Westsachsen	mittel/hoch	mittel	hoch	hoch	gering	hoch	mittel/hoch

Abb. 9: Zusammenfassende Bewertung des Instruments „Regionale Grünzüge“, Quelle: eigene Darstellung

6.2 Gesamtbewertung der Instrumentenverbünde

Eine vierphasige Instrumentenbewertung wurde für jedes untersuchte Steuerungsinstrument der Regionalpläne durchgeführt. Variierende Datengrundlagen und -verfügbarkeiten führen dazu, dass insbesondere die Teilbewertung des Soll-Ist-Vergleichs auf eine Interpretation der Evaluatoren angewiesen ist. Bei einzelnen Instrumenten ist die Durchführung einer quantitativen Erfolgskontrolle insgesamt nicht möglich. In diesen Fällen musste sich die Bewertung der Steuerungseffektivität auf eine tendenzielle Aussage beschränken. Im Folgenden wird die zusammenfassende Gesamtbewertung der Instrumentenverbünde der Regionen München und Westsachsen vorgestellt.

6.2.1 Gesamtbewertung Instrumentenverbund München

Die in der Region München zur Steuerung der Siedlungsflächenentwicklung genutzten Instrumente weisen mit Ausnahme des Instrumentes Bannwald maximal eine mittlere Steuerungseffektivität auf. Zentrale Elemente des regionalplanerischen Instrumentenverbunds sind negativplanerische Instrumente. Regionale Grünzüge, Trenngrün und Landschaftliche Vorbehaltsgebiete kommen jeweils über eine mittlere Steuerungseffektivität nicht hinaus.

	Plananalyse		Soll-Ist-Vergleich		Stakeholder-befragung		Vollzugs-analyse	Bewertung
	Restrik-tivität	Betroffenheit der Kommunen	Entwicklung folgt dem Plan	Uberein-stimmung FNP/RP	Zieler-reichung	Einschrän-kung Planungs-hoheit	Konflikt-häufigkeit	Steuerungs-effektivität
Zentrale Orte	gering	mittel	gering/ mittel	-	gering	hoch	-	gering
Bereiche, für Siedlungsentwicklung	gering	mittel	gering/ mittel	gering/ mittel	gering	gering	gering	gering
Organische Entwicklung	gering/ mittel	mittel	gering/ mittel	-	mittel	gering	gering	gering/mittel
Ausrichtung Entwicklung auf geeignete Haltepunkte	gering/ mittel	mittel	mittel	-	hoch	mittel	gering	mittel
Regionale Grünzüge	mittel	mittel	mittel	mittel	hoch	gering	mittel	mittel
Trenngrün	mittel	gering	-	-	hoch	gering	gering	Tendenz: mittel
Landschaftliche Vorbehaltsgebiete	gering/ mittel	gering	mittel	mittel	hoch	gering	mittel	mittel
Bannwald	mittel	mittel	hoch	hoch	-	-	gering	mittel/hoch

Abb. 10: Instrumentenbewertung Region München, Quelle: eigene Darstellung

Das Ergebnis verdeutlicht, dass diese Instrumente keinen hohen Freiraumschutz gewährleisten können, da im Einzelfall vielfach Ausnahmen zugelassen werden. Mit Blick auf die positivplanerischen Instrumente konnte bei der Festlegung zur Ausrichtung der Siedlungsentwicklung auf geeignete Haltepunkte des SPNV die höchste Steuerungseffektivität festgestellt werden. Hier gelingt es zumindest teilweise die Entwicklung auf die entsprechenden Standpunkte zu lenken. Demgegenüber ist die Steuerungseffektivität der Zentralen Orte, der Bereiche für Siedlungsentwicklung sowie der Festlegungen zur Eigenentwicklung gering. Bei diesen Instrumenten hat bereits die Plananalyse eine geringe Restriktivität gezeigt. Auch durch die Kommunen wird die Zielerreichung überwiegend negativ eingeschätzt. Zudem belegt der Soll-Ist-Vergleich nur eine geringe bis mittlere Übereinstimmung. Dieses Resultat bestätigt in Teilen die Aussagen von Reiß-Schmidt (2003, 747), wonach es in der Region München nicht gelungen ist, die Siedlungstätigkeit auf S-Bahn-Haltepunkte, Zentrale Orte und Siedlungsschwerpunkte zu konzentrieren. Die Steuerungseffektivität des Instrumentenverbunds muss insgesamt als gering/mittel bewertet werden.

6.2.2 Gesamtbewertung Instrumentenverbund Westsachsen

Auch im Instrumentenverbund der Region Westsachsen basiert die Steuerung der Siedlungsflächenentwicklung vor allem auf negativplanerischen Instrumenten (Regionale Grünzüge, Grünzäsur, Vorrang- und Vorbehaltsgebiete zum Freiraumschutz). Diese weisen eine relativ hohe Steuerungseffektivität auf. Eine Bewertung der positivplanerischen Instrumente muss sich mit Ausnahme des Instruments Zentrale Orte aufgrund mangelnder Datengrundlagen für einen Soll-Ist-Vergleich auf eine tendenzielle Aussage beschränken. Die Ausrichtung der Siedlungsflächenentwicklung auf die Zentralen Orte ist nur teilweise gelungen. Versorgungs- und Siedlungskerne sowie Siedlungsbereiche tragen kaum zur Steuerung der Siedlungsflächenentwicklung bei. Zusammenfassend ist die Steuerungseffektivität des Instrumentenverbunds der Region Westsachsen als mittel zu bewerten. Steuerungsmöglichkeiten besitzt die Regionalplanung vor allem im Hinblick auf eine Abwehr baulicher Nutzungen von Standorten, die dem Freiraumzweck vorbehalten bleiben sollen. Eine umfassende aktive Steuerung der Siedlungsflächenentwicklung gewährleistet der gewählte Instrumentenverbund nicht.

	Plananalyse		**Soll-Ist-Vergleich**		**Stakeholder-befragung**		**Vollzugs-analyse**	**Bewertung**
	Restrik-tivität	Betroffenheit der Kommunen	Entwicklung folgt dem Plan	Uberein-stimmung FNP/RP	Zieler-reichung	Einschrän-kung Planungs-hoheit	Konflikt-häufigkeit	Steuerungs-effektivität
Zentrale Orte	gering	mittel	mittel	-	gering	mittel	-	gering/mittel
Versorgungs- und Siedlungskerne	gering	mittel	-	-	gering	mittel	hoch	Tendenz: gering
Eigenentwicklung	gering	hoch	-	-	gering	hoch	mittel	Tendenz: gering
Siedlungsbereiche	gering/ mittel	gering	-	-	gering	mittel	gering	Tendenz: gering
Regionale Grünzüge	mittel/ hoch	mittel	hoch	hoch	hoch	gering	hoch	mittel/hoch
Grünzäsur	mittel/ hoch	hoch	-	-	hoch	gering	mittel	Tendenz: mittel/hoch
Sonstiger Freiraumschutz	hoch	hoch	mittel/ hoch	mittel/ hoch	-	gering	hoch	mittel/hoch

Abb. 11: Instrumentenbewertung Region Westsachsen, Quelle: eigene Darstellung

6.2.3 Zusammenfassende Einschätzung

Die Mengensteuerungskapazität der Instrumentenverbünde ist in beiden Regionen nur minimal ausgebildet. Dies hat insbesondere in der Region München den Effekt, dass der hohe Siedlungsdruck, der in keinem Stadt-Umland-Raum in Deutschland ein vergleichbares Niveau erreicht, nur unzureichend auf die besonders geeigneten Standorte mit sehr guter ÖPNV-Erschließung abgeleitet werden kann. Da der Immobilienmarkt in der Stadt München extrem angespannt ist, bedarf es auf den S-Bahn-Trassen leistungsfähiger Entlastungsorte, wo durch umfangreichen Wohnungsbau schienennah das Wohnungsangebot für die Region erheblich ausgeweitet werden kann. Gleichzeitig ist es erforderlich an den Standorten, die in der Region nicht über eine geeignete attraktive ÖV-Infrastruktur an die Landeshauptstadt angebunden sind und die nicht in ausreichendem Maße ein zentralörtliches Dienstleistungsangebot bieten, die Expansion der kommunalen Baulandentwicklung deutlich einzuschränken. Zwar ist dies auch mit freiraumschützenden Instrumenten möglich, eine effektivere Steuerung kann allerdings mit positivplanerischen Instrumenten der Mengenregulierung erfolgen, die in Bayern der Regionalplanung aber nicht von der Landesplanung zur Verfügung gestellt wird.

Das Defizit der Mengenregulierung ist in der Region Westsachsen nicht ähnlich stark zu spüren, wie in der Planungsregion München, da seit Ende der 1990er Jahre der Siedlungsdruck auf Standorte im Umland der Stadt Leipzig erheblich abgenommen hat. Wäre hier noch ein vergleichbarer Drang auf Standorte der „grünen Wiese“ gegeben, wie während der ersten Jahre nach der Wiedervereinigung, könnte die Expansion des suburbanen Raumes durch rein standortsteuernde Instrumente der Regionalplanung ebenfalls nur sehr eingeschränkt bewältigt werden. Da in diesem Raum heute nur noch ein verhältnismäßig schwacher Siedlungsdruck besteht und die Stadt Leipzig schon seit Jahren Reurbanisierungsgewinne verzeichnen kann, erscheint hier eine Erweiterung der Mengensteuerungskapazität der Regionalplanung nicht so dringlich wie in der Region München.

7 FAZIT

Eine entscheidende Rolle bei der Weiterentwicklung von praxistauglichen Planevaluationsansätzen spielt der Mix geeigneter Evaluationsmethoden. Das Refina-Vorhaben hat gezeigt, dass erst die Kombination qualitativer und quantitativer Methoden der Sozialforschung und der Raumwissenschaften die Evaluatoren in die Lage versetzt, instrumentenbezogene Planevaluationen durchzuführen, bei denen die Einschätzungen (Wirkungstheorien) unterschiedlicher Akteure integriert werden müssen.

Vier Aspekte sind bei der Planung von Planevaluationen zu berücksichtigen:

- 1)Intensivinterviews in der Sondierungsphase sind die Grundlage, um auf Seiten der Evaluatoren ein vertieftes Verständnis der Instrumente und ihrer Anwendung zu gewinnen. Unterbleibt eine Interviewphase, kann das Wissen externer Evaluatoren in der Regel nicht auf ein Kenntnisniveau heranreifen, das zur Formulierung ausreichend aufgeklärter Hypothesen über Wirkungen und Erfolg der Instrumente für notwendig gehalten wird.
- 2)Stakeholderbefragungen zu den Instrumenten des Regionalplans sind eine wichtige Grundlage, um nicht nur Einschätzungen über die Wirkungen von Instrumenten zu gewinnen, sondern auch um die Akzeptanz der Instrumente und ihren Reformbedarf abschätzen zu können.
- 3)Viele zur Verfügung stehende Verfahren der statistischen und geo-statistischen Analyse können nur dann sinnvoll für die Evaluation einzelner Regionalplaninstrumente angewendet werden, wenn hochauflösende, kleinräumige Geodaten in Zeitreihen vorliegen. Die Anwendbarkeit von Analysemethoden hängt somit entscheidend von den zur Verfügung stehenden Grunddaten ab. In vielen Fällen muss die Hypothesenbildung in Abhängigkeit von den nutzbaren Datenbeständen organisiert werden.
- 4)Wird das Gesamtergebnis einer instrumentenbezogenen Evaluation aus komplexen Teilanalysen abgeleitet, ist dem gesamten Bewertungsvorgang ein besonderes Augenmerk zu widmen. Bisher wurde eine qualitative Vorgehensweise praktiziert. Zu prüfen ist, ob durch quantitative Verfahren die Objektivität und Vergleichbarkeit der Synthese gesteigert werden kann.

Face to Face with Fantasy: the City of Utopian Places

Lineu Castello

(Dr. in Architecture, Professor, UFRGS [Universidade Federal do Rio Grande do Sul] / CNPq [Brazilian National Research Council, Rua Marquês de Pombal 1385 / 201 Porto Alegre 90540-001 Brazil, lincastello@terra.com.br)

1 ABSTRACT

Urban Happiness may not be just another utopia engendered by planners to lure citizens into the circuits of cities' real estate businesses. The Royal Institute of British Architects seem to look seriously at the topic, as suggested by the book edited by Jane Wernick on RIBA's behalf 'Building Happiness' (Black Dog Publishing, 2008). It brings the viewpoints of a varied number of authors about the pursuit of happiness as a meaningful political goal. On the other hand, recent developments in the theory of place, as I approach in my book called 'Rethinking the Meaning of Place' (Ashgate Publishing, 2010), seem to welcome the production of newly invented places (themed malls, revamped historic areas, etc) as important actors in the pursuit of happiness in today's cities. It is the intention of this paper to bring together the two lines of thought in order to achieve a better understanding of placemaking and placemarketing as techniques that promote the attractiveness of cities by producing new 'places of urbanity'.

2 THE ATTRACTIVENESS OF CITIES

You do not need to be an expert in urban studies to perceive that today's cities are experiencing a new trend in their concern with the offer of attractiveness, a trend increasingly observed in major global cities, all over the world and in all the five continents. There is nothing intrinsically new about this, however: people are used to flock to Lourdes, France, for example, simply for their happiness of being present in a place where a miracle has once been performed; similarly, in Ancient times, Romans crowded to Rome to watch Christians being shredded by hungry lions, just for the thrill of it. For them, this was a source of happiness. Both Lourdes and Rome were considered attractive cities, though by different standards. Herein lays an important first truism that helps to understand the slender difference between thrills and happiness, 'thrill not necessarily equaling happiness' (Schwartz, 2008:136). Cities' attractiveness though, either giving thrills or producing joy, has to do with the pursuit of happiness, a target frequently included within the consumption ethics that deeply permeates our twenty-first century society ideals. To be is to have, according to the principles of this society. But, to be happy, to have happiness, is often confounded with having (and being – which would be quite opposedly to the Heideggerian understanding, by the way). Accordingly, cities do compete among each other to become attractive both to visitors as well as to residents. This competitiveness is already acknowledged as an area of specific interest in urban studies, and some authors, such as Simon Anholt, for example, develop long elaborations on the topic (Anholt 2003; 2009), their basic arguments dealing, usually, with the branding that cities struggle to acquire in their competitiveness process. A sort of subdued competition seems to be in the order of the day among today's cities, that try to become known as, say, the City-light (Paris), or the World's Cultural Capital (New York), or the Carnival Paradise (Rio de Janeiro). This competition is often confounded with the supply of happiness, that is to say, cities attempt to allure people in terms of the amount of happiness they are supposedly able to provide them. As such, it is not surprising to find experts extensively discussing about this "pursuit of happiness" in actual urban environments. A good example of this is the recent publication named 'Building Happiness', encouraged by the Royal Institute of British Architects (RIBA), which approaches the subject with an unprecedented emphasis. The book is edited by Jane Wernick on RIBA's behalf, and presents a whole set of arguments focusing on the search for happiness as far as urban behaviours are concerned. Several authors and distinguished professionals bring about their opinions on what can be understood as happiness, insofar as living in urban environments is concerned. It is interesting to notice that, most of the times, attractiveness is understood as the power to produce happiness. So, in this context, providing happiness is often understood as a surrogate for cities achieving high attractiveness ranks in competitive grounds through the happy places they are able to produce. All in all though, a distinguishable point can be initially sorted out: more than ever before, happiness is actually for sale in contemporary cities. This is a first and important characteristic of these cities, especially for my area (Architecture-Urbanism), which is known for its crucial commitment to producing places for people – places designed for people being happy by using them. This search for happiness marked quite strongly the old heroic times of Modernist Urbanism in the early twentieth century,

as acknowledged in the above mentioned book. One of the authors quotes Le Corbusier saying that architecture produces happy people and that happy towns are those that have an architecture, an assertive that probably explains why 'Architecture thus becomes one of the most powerful mechanisms in the delivery of the promise of happiness on which modernity is founded' (Till, 2008:126, original emphasis).

2.1 The Production of Happiness

There are several tracks conducing to the production of happiness in present-day cities. Surprisingly, some of them are public and freely accessible, as some authors have more thoroughly examined (see, for example: Carmona et al. 2003; Carr et al. 1995; Kayden et al. 2000; PPS 2002; Whyte 1990). The majority of tracks, however, involve private and expensive businesses and it is on these grounds that the contributions of areas such as Urban Planning, Real Estate Development, and ICT Industry, can bring more practicable deeds. Fortunately, many of these areas's agencies seem to have understood the importance they play for heightening the attractiveness of cities, and their contributions have shown progresses accordingly. Indeed, the self-awareness of urban planning, for instance, can be clearly ackowledged in a statement I have recently selected and reproduced in a publication. The statement is part of a publicity campaign for a new urbanization in the state of Florida (USA), and it runs as follows: 'For those of us in the business of creating new places .... It's been said that great sculptors have the ability to unlock the image held inside a block of stone. In a sense, that's what great planners do as well. They strive to unlock the place held inside a piece of land' (apud Castello, 2010, forthcoming). Such an argument seems quite adequate to herewith introduce the topic of place and the close interrelationships the topic has to the question of the production of happiness.

Places have a strong phenomenological connotation nowadays. Going to a place, enjoying the experience a place has to offer, may sometimes double with being happy, double with happiness. Traditionally closer to the Humanities, the concept of place has expanded its reach up to a point in which it now touches several disciplines simultaneously. One can say that the concept now acquires a supra-disciplinary status, that encompasses sociological, anthropological, geographical, tourist, cultural, philosophical, architectural, environmental and spatial themes, and, somewhat rather unexpectedly, also touches themes more closely related to administrative, managerial, economic and political grounds. Definitely, the concept of place can be said to have reached a transdisciplinary range nowadays. In fact, the importance of the concept for the goal of 'liveable, healthy, prosperous cities for everyone' cannot be sufficiently overemphasised, since it is its foundational aim to design spaces for people to live in and to enjoy living experiences in suitable civilized conditions: 'Architectural psychology, environmental psychology, people/environment studies, human factors of design or psychostructural environics, call what you may, has been concerned explicitly in making better, happier and more humane environments' (Mikellides, 2008:86). In other words, places are crucial for the production of happiness in urban surroundings. Architects, in their best knowledge and good will, diligently tried to design places, though they did so under the strict Modernist functionalist rules. Some way or another (and this is a long discussion), the places did not work. At the end of the day, architects became tired of assuming the blame of designing what became branded as placelessness (Relph 1976; 1996) or, even more pessimistically, non-places. This contributed to set up a contemporary rethinking of the concept of place: once one of the noblest principles in Architecture-Urbanism, the concept of place has now incorporated a double meaning in today's practice of urban planning. On top of its traditional social meaning, a Place can now incorporate a strong economic meaning, thereby acquiring an additional urban function: the concept today also deals with urban economics. This is a second important characteristic of contemporary cities. The making of a place now comes together with the marketing of that place – Placemaking doubles with Placemarketing – and the newly formed duet assemble forces to jointly work towards the production of happiness, and, hence, rather unpredictably, to encourage the creation of a (sort of) market of happiness. This is an entire new aspect in the theory of place, and deserves a little more elaboration, insofar as the concept of place moves from the previous functional bias it used to have in Modernist Architecture-Urbanism, and favours a more phenomenological approach now, in post-modern times, reflecting the important existential role of the concept and its protagonism as an environmental nexus that registers the anthropical transformation of the human environment.

2.2 The Market of Happiness

Most actions involved in the making of a place call for the participation of an architect or a planner. As a matter of fact, in this respect, there are many complexities that end up in the hands of architects, who on top

of having to respond to intricate and unforeseen changes being constantly introduced into urban realms, '… still face the challenge of shaping public space – from piazza to Plaza…. Indeed, architects are actively searching for new forms in which to house contemporary public life' (Avermaete et al., 2009: 19). This is a challenge considerably bedevilled by the fact that the public realm undergoes a continual change, starting by the startling change brought about by the new ways of perceiving what is public and what is private. This is a third important characteristic of contemporary cities. French philosopher François Ascher recognizes quite clearly these perceptual changes by stating that in certain situations, the social practices performed in a place are the real cause to confer to that place its public character (Ascher, 1995; 2008). In other words, the traditional prerogatives that used to establish the distinction between public and private seem to be no longer in force; at least, in the strict sense they used to have. The three pronged public-private distinction established long time ago (in fact, during the French Revolution, 1798), based on ownership, accessibility, and purpose (Avermaete et al., 2009:25), has experienced a thorough change, and, today, there is a kind of "democratization" in terms of what is considered as public domain, and a classic example is provided by the sociologist Sharon Zukin who points out to the fact that the access to the (semi)public spaces of shopping malls becomes de facto public spaces (Zukin, 1997).

In present times one can discern a factual typology of places distributed right through the whole extension of urban environments. In my research work I signal to three types (and to their specific variations): I call them places of aura, places of memory, and places of plurality (Castello, 2010, forthcoming). Places of Aura are those originated from spatial stimuli, material or abstract. Places leaning upon traditional or historical elements associated to temporal dimensions I term places of Memory. And places stimulated from the interaction among people due to their interpersonal relations in the environment are termed as places of Plurality. All types can be responsible for the production of happiness and to attribute quality to urban spaces. All types can deliver whatever utopias and fantasies people are daydreaming with. Moreover, all types can be also responsible for offering what is known as "urbanity", an environmental quality inherent to urban areas. This quality can even be understood as a surrogate for happiness, that is to say, once you are in the presence of urbanity, it is likely that you may embark on a experience that will involve happiness.

The difficult point is that you must pay to use many of these places of urbanity (or of happiness). In contemporary times, it is as if a "market of happiness" became institutionalized in certain urban areas. Significantly, it is precisely here that the contributions of Urban Planning, Real Estate Development, and ICT Industry areas become substantially decisive: they can make this market more accessible and, hence, THEY CAN MAKE CITIES MORE ATTRACTIVE!

Though this contribution is sometimes quite explicit, like the celebrated case of the reurbanization of PotsdamerPlatz in Berlin, Germany, in many occasions it remains understated, like in the rehabilitation of neglected old central quarter's areas, like the Bastakia zone in old Dubai, United Arab Emirates.

It follows some illustrations of places of urbanity in different cities and continents that include either implicit or explicit external contributions from various development agents.

3 HAPPY PLACES ARE HERE TO STAY

And which are those places?

Even if presented under very different configurations, mostly daily reality cases include illustrations that encompass shopping activities and services industries, such as entertainment, culture, leisure and tourism. In fact, the absolute majority of the newly invented places is constituted of commercial and services activities like shopping malls, recycled historical settings, restaurants, entertainment places, sports complexes, hybrid complexes, multiplex cinemas, museums, libraries – places which try to "clone" qualities found in consecrated other places, or which create what is believed to produce the urban attractiveness known as urbanity.

As mentioned earlier, one of the most renowned illustrations of newly invented places of urban attractivity comes from Europe. The reurbanization of the PotsdamerPlatz area in central Berlin, an area heavily destroyed by Second World War bombings is, undoubtedly one of the most expressive examples of the creation of public places by private agents. In this case, the initiative came from Daimler-Benz-Chrysler and from Sony Corporation, among others agents (FIGS. 1-2). One of the most interesting actions to highlight in this case is that the reurbanization involved both space and time determinants, as if illustrating one former

assertive by Zaha Hadid about her '…idea that one could return to a previous moment in time….to investigate the issues of that time and what they could imply in terms of change and newness…. Juxtaposing two "times" created a superimposition and, eventually, hybridization. Things that had occurred at different times could now happen simultaneously' (Hadid, 2009:141). The space that located PotsdamerPlatz before war times was a great central place. The space that locates PotsdamerPlatz in today's times is a great central place again.

Fig. 1: Berlin. Arrival to PotsdamerPlatz Station, Fig.2: Berlin. PotsdamerPlatz, Sony Area

Striking examples come from Asian countries, mainly from those once referred to as the Asian Tigers. Bangkok, Thailand, pioneered in shopping cutting-edge activities, by introducing the strategy of allocating a grouping of various shopping malls in a single key central area known as Siam (FIGS. 3-4). A similar situation is found in the island of Singapore, where there is an enormous succession of huge malls that parade along a single avenue, the busy Orchard Road (FIGS. 5-6). The United Arab Emirates, in turn, provide the legendary example of Dubai, perhaps the most fantastic private development in the whole world, with its palm-shaped islands, and the like. But that can also be renowned for a beautiful piece of heritage preservation, presented by the historic area known as Bastakia, a beautifully successful refurbishment in the city's oldest area (FIG.7).

Fig. 3: Bangkok. Public areas shared by shopping malls, Fig. 4: Bangkok. Siam Area

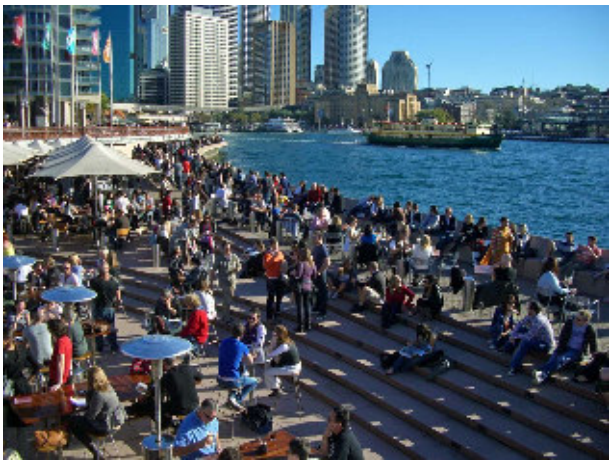
Fig. 5: Singapore. New Ion Orchard Mall, Fig. 6: Singapore. Orchard Road

Cultural activities are prodigal for inducing the creation of attractive places, and one classic illustration of this trend comes from Africa, in Cairo, Egypt, with the creation of a genuine entertainment park in the Gizeh area of the pyramids, offering not only the expected historical emotions, but also the Sound-and-Light attractions that ultimately entice the establishment of lots and lots of retail outlets, services and leisure industries (FIG.8).

Fig. 7: Dubai. Bastakia Area, Fig. 8: Cairo. Gizeh Area

Oceania has excellent examples from down under, and probably the most distinguished ones are located in Australia. The Sydney Opera House, for instance, established itself as a celebrated place which soon earned the status of a national brand for the country as a whole. Today, it is a fêted place for Sydney inhabitants and for world tourists alike. Perhaps only the ensemble composed by the area named Darling Harbour can rival to the Opera House area as one of the legitimate places of urbanity in Sydney (FIGS. 9-10).

Finally, illustrations in North America are copious, since it was there that the highly successful practice of creating thematic places, like Disney's theme parks in Florida and California, festival places like South Street Seaport, in New York, and entertainment fantasies, like Fisherman's Wharf in San Francisco (FIG.11), were actually born. New York excels in the practice of creating "public" places – though, at the end of the day, privately owned. The initiatives of William H. Whyte, who successfully negotiated and bargained with private investors for the insertion of public spaces in their developments, became worldwide celebrated. A detailed book organized by Jerold Kayden, the New York City Department of City Planning, and the Municipal Art Society of New York, suggestively titled "Privately Owned Public Space", registers with minutiae this New York City experience.



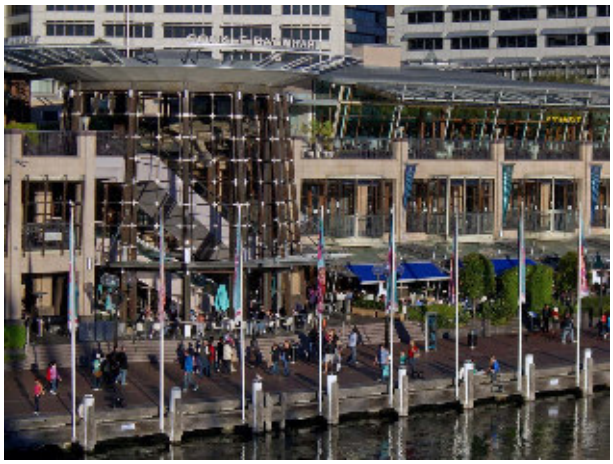


Fig. 9: Sydney. Opera House Area, Fig. 10: Sydney. Darling Harbour Area

But South America follows short, not only by emulating North American theme parks and fantasy places (Hannigan, 1998) as by introducing up-to-date technicalities like, for example, the creation of airports that double as hybrid complexes, intended for the generation of public places. This latter case is quite clearly illustrated by the airport of Porto Alegre, Brazil, my home city, to which I will grant some extended notes.

Fig. 11: San Francisco. Fishermans Wharf Area, Fig. 12: Porto Alegre. Central Location of Airport

In Brazilian terms, the refurbishing of the International Airport Salgado Filho, in Porto Alegre, has brought innovation to the airport national scene by creating a multifunctional mega-complex – a veritable city-building – as it is increasingly found in major airports across the world. Its programme combines very diverse activities, such as shopping mall, leisure and entertainment spaces, transport terminus, medical and clinic services, exhibition and museum spaces, hospitality and food services. It generated a concentration of hybrid buildings that seek to play a similar role to that found in urban commerce and service centres. The building's surroundings the airport also added further functions to the complex, with international hotel chains benefiting from direct links to the city's overground-metro system's Airport station, and new road axis into the city centre or to towns in the metropolitan region. Further to that, comes the unusual proximity to Porto Alegre's central area, easily accessible from the complex (FIG.12), collaborating to explain the quick success the complex achieved in becoming a place of attractiveness for the city's population. The variety of functions acts as a catalyst to generate an atmosphere of plurality. The architect Bernard Tschumi sees airports as an opportunity for the creation of places. In the project for Kansai, in Osaka (Japan), for example, he sought '... to enlarge the airport into an event, a spectacle, a new city of interchange and exchange, of business, commerce and culture (…)' (Tschumi 1994:105). In Porto Alegre, it can now be asserted that the plural space of the Airport Complex is also starting to be perceived as a place, attracting a good number of people, including inhabitants and tourists who visit it to enjoy the incipient 'urbanity' created there, frequenting the airport simply to have a coffee or read a newspaper in a comfortable and safe place – using the airport as a tertiary place, as Oldenburg (1999) teaches us. Or simply to go shopping, flirt in the food hall, show an attractive place to a friend, watch one of the new releases in the cinemas, since Porto Alegre's airport was the first to offer a cineplex in Brazil (FIG.13), or just for an enjoyable visit with family

or friends. Furthermore, it is now possible to talk of an expansion of 'placeness' at the airport: in April 2005 the space in front of the airport Complex was chosen to house the 'Cidade Elétrica', an especially assembled mobile structure for popular mega-events such as major pop concerts. On a 40,000-m2 site in the Parque Condor, the Cidade Elétrica is equipped with food plazas, chemical toilets, and first aid and security systems. The opening event involved especially run public transport using the Airport metro station as transfer point, enabling access to one more event associated with the plurality connected with the airport place, indicating it as a source of an agglomeration economy. Confirming the trend, this space currently houses the 'Pepsi on Stage', a venue for popular rock shows, heavily attended by young people from all parts of the city, and organized by Pepsi-Cola.

It is also worthwhile registering that Porto Alegre has recently engaged on yet another production of a public attraction promoted by the private sector. As it happens in other parts of the world, the city's cultural scene got enriched by the construction of a grand new art museum, sponsored by the "Fundação Iberê Camargo", a private Foundation, dedicated to a local artist. One of the most exciting attractivity factors presented by the museum is its design by one world-famous Portuguese architect, Alvaro Siza, winner of the 1992 Pritzker prize, who won, for his Porto Alegre project, the Lion d'Or from the Venice Architecture Biennial of 2002, while still in blueprint phase (FIG.14).

4 CONCLUSION

But, ultimately, what is happiness? This, of course, is an extremely delicate question.

'Happiness is a by-product of numerous human emotions triggered by the convergence of many things: a sense of security and belonging, an association of pleasant memories, a connection to the past and to the place, a 'positive' (of course, relative and subjective) aesthetic where one feels uplifted, a sense of possibility and openness, and an impression of choice' (Scwhartz, 2008: 134). It goes without saying that the projects mentioned in this paper deal, one way or another, with at least one or many of the things included in this emotion known as happiness. Since the projects show clear engagements to entrepreneurial corporations, they clearly contain heavy arguments for understanding the crucial role played by entities such as Urban Planning, Real Estate Development, and ICT Industry areas in the creation of places of attractiveness in contemporary urban environments. They also represent a clear illustration of the role of a new economic urban component – the creative economy – as an important instrument of urban development (Florida 2004; 2005), which has been incorporated into the repertoire of strategies of urban planning and urbanism that seek new paradigms for meeting the growing concern with increasing the attractiveness of cities, to transform them into places people feel increasingly attracted to live in, work or visit.

Lastly, there are three arguments worth remembering, in order to better understanding the actual conclusions: (i) Architects have been constantly working for the pursuit of happiness, this pursuit being an explicit objective of the Modernist period, as observed by Le Corbusier. (ii) The Making of Places in Post-Modernist times received a crucial help by the newest area of Placemarketing; in Modernist times, traditional place design led to placelessness and non-places. (iii) The boundaries between private and public space have become very thin and seemingly, tend to become even thinner along the twenty-first century public-private initiatives in urban areas.

Whether acceptable or not, the three arguments do not represent more than just a single step towards the provision of better cities for people. 'Architects have a duty to respond to social changes, but they also have a leading role to play in redefining concepts like public and private' (Avermaete et al., 2009:49). To this matter, I conclude with some disquieting and thought-provoking arguments expressed by Juhani Pallasmaa, who remind us of the long way we still have to pursue towards our goal of better cities:

'Are the problems that guide the formation of the public sphere, perhaps, entirely beyond the grasp and control of architecture and the conscious intentions of the architect?...Are the reasons for the loss of the public dimension perhaps hiding in the invisible mechanisms and structures of modernization, globalisation, mass production and consumption, mobility, constant change, economic power structures and the processes of shrewd profit making?...Have we become servants of today's cultural processes instead of directing those processes ourselves?' (Pallasmaa 2009: 128).

1 ABSTRACT

Since the mid-1950's Freiburg im Breisgau has experienced big growth in both population (ca. 62%) and in the number of workplaces. This trend has been still present in the last two decades (ca. 17%) what is not common among German cities. The city must balance between rising number of cars caused by rising population and the quality of life which attracts new inhabitants and new investors mostly in high-tech.

In attempt to alleviate growing demand on transport, the city extended the tram network and new lines have been constructed to serve areas of new settlement. It is a tool for making transport behaviours more sustainable and to keep low share of cars in the modal split and the tram lines are the backbone of the urban development, especially for new housing areas. The chance for the region is seen in using existing rail tracks for a development of a regional train network. The most important key to success is coordination of urban development and transport policies.

This paper presents the experiences of the city of Freiburg and the region. It focuses on three most important aspects: transport solutions for new settlements within the city limits (Rieselfeld and Vauban), development of regional train connections (inter alia Breisgau-S-Bahn) serving the growing towns and villages in the surrounding region and quality of non-motorized traffic in city centre. The authors evaluate the applied solutions and they show that urban growth can go hand in hand with sustainability and can be used for modal split improvements.

2 INTRODUCTION

Freiburg (full name: Freiburg im Breisgau) is a middle-size (about 220 000 inhabitants at all) university city (hosting almost 30,000 students) in south-west Germany. Surrounded by the Black Forest Mountains and located in the foothills of the Schlossberg, city straddles the river Dreisam. The location causes the specific shape of the city but city is relatively flat. There are not any natural barriers for cycling and for relevant tram network construction.

The city plays an important role for the surrounding region. Around 95,000 people are employed in the city. In 2003 around 68,000 commuters travelled daily into the city to work, and some 16,000 residents commuted to jobs outside the city. Most of commuters (65%) go to or from Freiburg by car. The city has witnessed systematic growth of commuters from region and to region. In 1970 there were only 34,000 commuters to the city and 3,000 from the city, in 1987 adequately: 53,000 and 8,000 and in 1997 – 64,000 and 14,000. Additionally, the city attracts about 3 million tourists a year.

The city is located on the Mannheim-Basle railway also known as the Rheintalbahn which is one of the heaviest used railways in Germany. The city is also served by the A5 Frankfurt am Main - Basel motorway (located on western suburbs) and three federal roads.

According to the last traffic survey in 1999 (Verkehrsentwicklungsplan, 2002) the modal split was: walk – 23%, bicycle – 27%, public transport – 18%, car drivers – 26%, car passengers – 6%. Freiburg has been witnessing a significant improvement of transport sustainability. In 1982 it had been respectively: 35%, 15%, 11%, 30% and 9%. The huge reduction of car use was possible thanks to a lot of different measures. The best known of all these was the introduction of cheap monthly ticket called "Umweltkarte" ("environmental card") in 1984, present named "Regio-Karte" ("region card").

According to FritzRoy and Smith (1998) the success of public transport in Freiburg can be chiefly accounted for by the introduction of a cheap travel pass in 1984 with the essential characteristics of unlimited use at zero marginal financial cost, interpersonal transferability and wide regional validity. Although the rules of ticket have been changed partly – e.g. there was introduced a not transferable monthty ticket a little bit cheaper, the popularity of "Regio-Karte" is still high. About 86% of all trips using public transport in the city

are done by owners of monthly or yearly tickets (Statistisches Jahrbuch, 2009). But this well known ticket is only one pillar of the sustainable transport policy in Freiburg.

The strategic Transport Development Plan (Verkehrsentwicklungsplan, 2020) sets goals to reach until 2020 even more sustainable modal split: walk – 24%, bicycle – 27%, public transport – 20%, car drivers – 24%, car passengers – 5%. Therefore a lot of different measures shall be implemented in the next years, to promote urban friendly modes of transport. On the one hand there are traffic management activities like extension of the tram , development of cycle infrastructure, or the pedestrian traffic quality improvement; on the other hands are urban planning tools like limitation of spatial development, better utilisation of inner-city areas (braunfield investments), mixed use (traditional neighbourhood design). It is worth to underline that the goal can be reached by the synergy of these different activities.

3 HISTORY OF TRANSPORT MANAGEMENT

Freiburg has many advantages for sustainable development. The city has never destroyed the historical centre to improve the car accessibility and the phase of the modernism in urban planning did not leave its strong stamp on urban structure. It was huge difference to some other German cities which had car-oriented transport policies. In those cities the changes have come slowly after the 1973 oil crisis.

Furthermore, in 1969 the city introduced first Integral Traffic Plan. The Plan respected interests of non motorized inhabitants although the main planned form of transport were private cars. Two years later the Cycle Path Network Plan was carried out and passed the city council. Cycling became an important part of transport policy. In 1972 the city decided to retain and expand the tram network. The development of tram network based on modern concepts: separated tracks, priorities on intersection with traffic lights, higher average speed. The name for this new tram system is "Stadtbahn" ("urban rail") instead of "Straßenbahn" ("tramway"). In 1973 the entire city centre was converted into a pedestrian zone. It created good conditions for pedestrian traffic and started new urban culture with significant role in shopping of Old Town and rising importance of walking, cycling in transport behaviours.

After a decade in 1979 the new Integral Traffic Plan passed the city council. It gave equal priority to pedestrians, cyclists, public transport and individual motorized vehicle traffic.

The next transport document was approved a decade later – in 1989. The Comprehensive Traffic Plan has already different objectives to reduce of car traffic volume. Two main tools were the promotion of environmentally friendly modes of transport and the distinct restrictions for car traffic. Over the last decades Freiburg has become well known for its model measures in environmental protection. In this context conclusive Integral Traffic Plan has made a key contribution. Freiburg's Integral Traffic Plan thus compromises a clearly differentiated integral system with the sectors: local public transport, cycle traffic, pedestrian traffic and motorized vehicle traffic. The main goal of the traffic plan is to reduce the negative effects of car traffic in order to an improvement for living and environmental conditions in our city.

The newest Transport Development Plan (2002) brings continuity. The same objectives are still on the agenda: better quality of life, better public transport, better conditions for pedestrians and cyclists. The plan adjusts the goals to new conditions: the growth of population and the spatial development.

4 LOCAL PUBLIC TRANSPORT INFRASTRUCTURE DEVELOPMENT

Simultaneously to more and more environmental friendly transport policies there has been progress in development of local public transport infrastructure. Trams should be the core of the system and the extension of the tram network has become a central factor in our urban transport policy. The first modern track based on concept "Stadtbahn" ("urban rail") was opened in 1983. It connected the high density residential areas located on western part of city with the city centre. Two years later the track was extended to a new neighbouring settlement. In the 1980's there was one more investment – optimization of tram network in the city centre (one track was moved to other street).

According to the natural conditions – limitation by Black Forest – the spatial development is in principally in western direction. The main investments in tram networks have been done and are planned in western districts.

Next investments, also in western districts, were done in the 1990's: tram track to industrial area (1994) and to Rieselfeld – model district (1997). It worth to underline that the line to Rieselfeld had been opened before the contraction of new district was finished.

In the late 1990's there was a broad discussion about the next steps to extend the "Stadtbahn" system. It also was a discussion about transport policy and its implications on urban development. The city government planed in the late 1990's to construct a new line connecting the city centre with the new urban areas in the south west of Freiburg. All lines come together at one intersection, the Bertoldsbrunnen, the historic heart of Freiburg, the spot the city was founded 880 Years ago. The Freiburger Verkehrs AG argued that this intersection is not longer able to cope with all the old and new tram lines and will become a bottleneck for further extensions. The company suggested to build a new bypass beside the historic town centre. The discussion was very complex but the key question was: where is the heart of the city? All the people, including the retailers argued that it is the key that the new trams line have to bring the people to the heart of the city. The government and members of the city council argued that the city centre can no longer be the historic town alone but has to be extended to the west. As already mentioned the urban development did go west. But most members of the council voted that the new tram line has to go directly into the historic town, like all the others do. There were broad and controversial discussions over years, in 1999 there was a public referendum with no clear result and at the end the majority of council members decided to connect the new tram line to the historic Bertoldsbrunnen, and it was build this way.

This dispute delayed the development. So the new line to Haslach was constructed in 2002/2004 and was basis for the long awaited tram line to by Vauban inhabitants a connection to city centre (opened in 2006).

Now, ten years later, the inner city bypass is part of the new extensions plans and in the future the planned network will allow both, to serve the historic part of the city and to bypass the city on new line.

At the current time, further line extensions are planned, extending the tram network by more than 50% to 33 km. The plans have three important investments: the already mentioned inner city bypass (allowing to avoid tram, pedestrian and cyclists overcrowded Bertoldsbrunnen – see fig. 6), north-western extension to new university campus and Freiburg fairs area, and eastern extension to train station Littenweiler and district behind the station. This extensions will mean 83% of Freiburg's inhabitants and 88% of places of work will be directly accessible by tram within a 600 m radius from stops.

The tram must be fast and comfortable to be successful. Speed is achieved when the tram has its own track independent of private car traffic on the roads. All new lines will have their own track, partly running together with the cars but having priority by traffic signals and traffic management and existing lines will be converted wherever possible. At the same time, a swift tram journey is achieved by priority traffic control.

The buses, partly running on separate lanes, have a shuttle and supplementary role to the tram network.

It is worth to mention that there is wide public participation at development of tram network. The northern extension of tram network (planned to be constructed until 2012) was consulted with inhabitants in frame of an international project – "GenderAlp", as a task "Implementing Gender Mainstreaming in spatial planning". The idea of this project was to find new ideas for participation. Public participation was seen as toll for quality-management in the planning process. The gender approach was used to plan the participation of a new tram line and it should be a requirement oriented. The second idea was the implementation of gender mainstreaming in the technical and planning departments of the administration and to develop new guidelines for participation. The result of this broad participation was an unanimous vote for the tram extension in the city council and a easy and fast legal procedure with no caveat.

5 NEW SETTELMENTS

One important sign of Freiburg's sustainability policy are two new quarters: Rieselfeld and Vauban. The well-known solution is Vauban, although the beginning, due to delays caused by problems with construction new tram line. The planned measure of efficiency of integrated urban and transport planning was before of all the reduction of car trips number and motorization level (Cerfontaine, 2007; Nobis 2003, Ryan, Throgmorton, 2007).

The motorization level of all Vauban in 2008 was 167 cars/1000 inhabitants. Higher level was observed in Rieselfeld, the second model district of Freiburg – 290 cars/1000 inhabitants, while the average level for whole city is about 392 cars/1000 inhabitants. Since the 1990's the level of motorisation had been stable (oscillating about 450 cars/1000 inhabitants) but since 2007 Freiburg has been witnessing rapid decrees of motorisation level (see fig. 1).

The goal of the traffic concept was not to create a small, car-free district for environmentalist but to establish a whole district where car is not needed for life. The stress was to reduce the use of cars, not to ban the car in the district. The most important tool to create these behaviours was the idea to have no parking direct beneath or under the homes nor in the residential streets. So most of small streets close to homes are excluded from parking. There is allowed only short term parking for deliveries of goods (e.g. shopping) or to pick-up someone. So there is only a very few motorized traffic and that improves the quality of living, because there is less noise and more safety especially for children. The car can be parked on the main street of district but there is at weekdays between 9:00 and 19:00 a paid parking zone mandatory also for inhabitants. Inhabitants having cars have possibility to buy a place in one of three multi-store car parks. They are located on the district edges. This makes public transport easier to reach – tram stops are usually closer to homes than the car parks. Additionally, short distance to walk to the next shop or to the next cafe is a barrier to frequent use of car. No parking at door steps is called as "parking-free living", not a quite new idea but seldom transferred to reality in the way Freiburg did.

German local or regional law forces the developers to have an appropriate number of parking places (for cars and also for bicycles) depending of the usage of buildings. The cost of this rules are usually paid by all inhabitants, having car or not having car. In Vauban is different: families without cars are exempted from participating in the costs of community car park. Car-free inhabitants thus save the substantial money of a parking place. The restriction for parking on streets make impossible to park for free a car in Vauban. If someone decides to have a car, he needs to buy a park place in multi-storage garage.. And the concept provides also an idea if there is a strong shift in travel behaviour in the future and all people in Vauban will have own car. Although there is no trend in this direction at all, the concept would allow to build one more multi-story car park in the Western Edge of the area, but this parcel is still a green area where children are playing.

The whole transport policy for Vauban district is based on "push and pull strategy". Only restrictions for cars could not be successful. In exchange for limitations for car inhabitants receive good public transport: high

frequency (at work days every 7,5 minutes, and at Sundays every 15 minutes) tram line to the city centre and the bus connection to some suburbs.

There is planned to build at the closure of the tram terminus the station for regional rail. It is worth to mention that on the one hand this is an element of mobility concept for Vauban on the other hand this is a part of public transport strategy for Freiburg and region – to make intermodal stops on all regional rail tracks. Thus passengers going to targets located in the city but before the city centre (riding from home) are not press to ride by train to main station and come back by tram. It allows not only to short travel time but to balance the passenger density in trams: to reduce in the city centre and to rise on suburbs.

Inhabitants without car can use special offer of car sharing association (Car-Sharing Südbaden - Freiburger-Auto-Gemeinschaft e.V.). These cars are addressed especially to Vauban inhabitants and the cars park on district. Additionally, those residents who joined the car sharing association receive a one-year free pass for all public transportation within Freiburg and "BahnCard 50" a loyalty card offered by Deutsche Bahn, allow passengers to get 50% discount on standard rail fares (Enocha, Taylor, 2006).

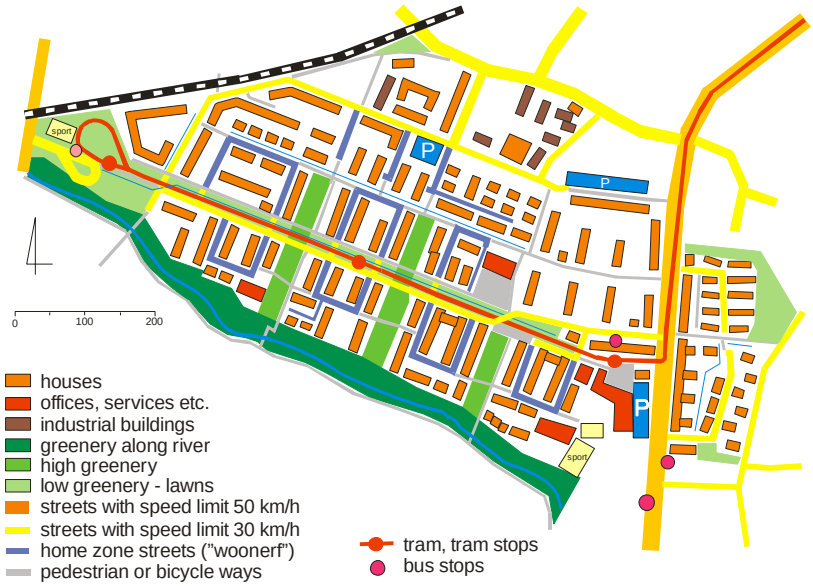

Fig. 2. Vauban district in Freiburg (source: own compilation based on Open Street Map)

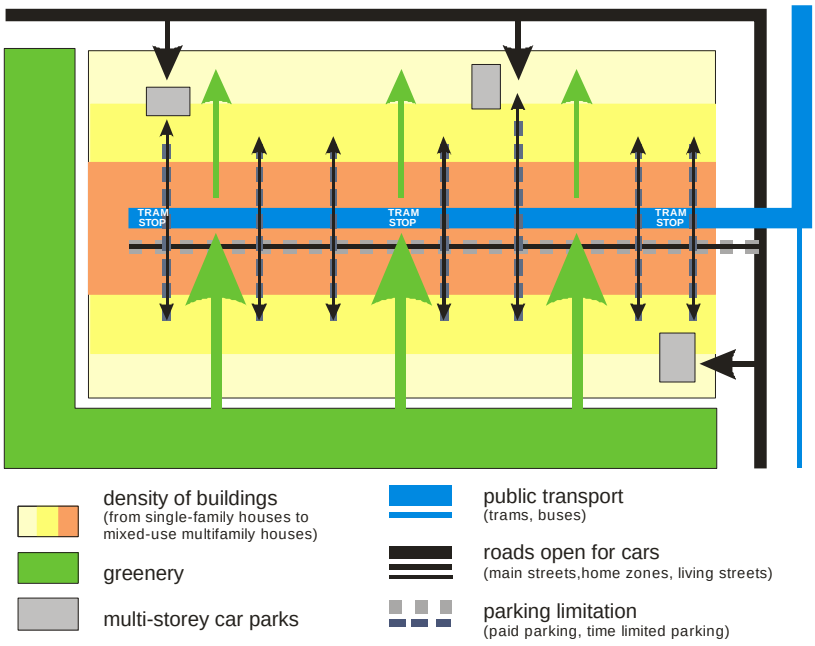

Fig. 3. Idealized schema of modern sustainable settlements in Freiburg (source: own compilation)

The most important factor of car use reduction seems to be mixed land use. The plan of district is based on the traditional neighbourhood design. The population density is fairly high what makes tram connection

relatively profitable (Apel et al., 2001; Loose, 2001). The most important services like school, kindergartens, a farmer's market, a shopping centre, restaurants, cafes, are within walking distance. On the district are about 600 workplaces. Access to recreation is very easy – the district is cut by three axes of greenery (see fig. 2 and fig 3.). This type of urban design can be called as "fractality". Each part of settlement is a district in miniature: houses, greenery, services.

6 REGIONAL TRANSPORT

A successful public transport policy can no longer be limited to a city's own boundaries, but instead it must operate regionally. The neighbouring counties: Breisgau-Hochschwarzwald and Emmendingen have collaborated with Freiburg to form a metropolitan area joint public transport association. The city in co-operation with neighbouring counties has successfully started to expand our integrated rail and bus system. The most important project is the "Breisgau S-Bahn" (Suburban Rail in Breisgau Region) (see fig. 4).

The Land of Baden-Württemberg is supporting the public transport association in this venture. At a cost of 400 million EUR, this plan envisages a regional rail system also integrating Freiburg's tram network and the regional and local busses with closely coordinated timetables interlinking the whole region.

This plan will help to shift the balance considerably in favour of the public transportation network. The extension of the public transportation network in metropolitan area is one of the main factors in the policy of the coming decade, supported by all the relevant political groups.

The first line of these integrated regional local traffic system started operation between Freiburg and Breisach on the Rhine River in 1998. This rail system is being complemented by a dense bus network to cover the communities without own train station.
The accessibility of the suburban rail system and the tram network must be improved with transfer possibilities for cyclists (Bike&Ride) and car drivers (Park&Ride). Up until now, more than 2,600 P+R parking spaces have been established in the city of Freiburg and about 2,400 at the stations throughout the region. Bicycle parking spaces are already available at many stops and train stations, where the bicycles are protected against theft, the wind and the weather. These options will be expanded consistently over the coming years.

The railroad to Breisach two decades before was planned to be closured. The introduction of a suburban rail (Breisgau-S-Bahn) in regular tact and integrated with Freiburg's fare system has changed the inhabitants transport behaviours. At present, trains at weekdays operates every half hour but demand is higher. Thus there are plans to extend to twin track railroad and to electrify. The planned frequency at weekdays is every quarter.

Fig. 5. High frequently suburban rail (Breisgau-S-Bahn) was an impulse for housing estates development in the vicinity of the train stations. Ihringen. (Photo: M. Beim)

7 PEDESTRIAN AND CYCLING FRIENDLY CITY

The main focus of Freiburg's transport policy is to provide attractive alternatives. This is generally the better and more effective approach than imposing restrictions and bans.

Nevertheless, certain restrictions are naturally unavoidable within the frame-work of traffic policy. The most far-reaching restriction is the creation of car-free areas and pedestrian zones. As early as 1973, Freiburg converted the entire historic part of the city into a pedestrian zone, incidentally against strong initial protest by the shops affected. It is almost impossible to imagine our main street in the heart of the city, Kaiser-Joseph-Straße, was the Federal highway along which the entire motor vehicle traffic from North to South only a few decades ago was squeezed through the Rhine Valley. Characteristic for the Freiburg pedestrian zone is that the shops and department stores can be reached directly very easily by bus and tram.

The total length of pedestrian areas in 2008 was 8 535 m including 6 938 m pedestrian zones partly opened for deliveries. The network of pedestrian streets has not been extended in last years.

The importance of cycle-oriented traffic policy, i.e., providing a further alternative apart from the public transportation network is misjudged too often. The special attraction of the cycle policy is that within a short period and with only little investment and follow-up costs, it is possible to achieve tremendous changes. This is especially important in times of tight budgets.

Since the 1970's, the city of Freiburg has enlarged the cycle ways network to 99,5 km. During the first few years, the main emphasis was given to expanding the cycle path network at the city outskirts, which could also serve for cycle trips. In more recent years priority has been given to increasing the extension and structural alteration measures designed to lead cyclists into and across the inner city. In addition to extending the cycleway network, we must carry out other related measures. In this context, over the last few years over all more than 8.000 cycle parking spaces have been provided, some as a result of reallocation of existing car parking spaces.

Cycle traffic causes sometimes conflicts with other users, especially with pedestrians. The cycle facilities in Freiburg are designed to avoid this. The cycle lanes on roadways are preferred in cases where car speed is limited to 50 km/h. In traffic calming zones ("Tempo 30" or living streets) cycle traffic is on roadways without special facilities (one exception are contra-flow lanes in one way streets). Only in case of low pedestrian and cycling traffic are common ways for both groups of users. In the area of the main tram stop "Bertholdsbrunnen" was introduced a strictly bicycle parking prohibition (see fig. 5). This rule caused huge controversy among cyclists but it was needed to ensure good quality for public transport passengers changing trams. And today there are no more discussions and the parking system works sufficiently for everyone. The cyclists find a place (in distance about 100 m from Bertholdsbrunnen) where they can leave and lock their

bicycles and the tram passengers can chance the trams and the pedestrians can walk around without parked bicycles as a barrier.

Remarkable in 2009 is the introduction of special mirrors called "Trixi-Spiegel" which allow truck and car drivers to observe cyclists riding on cycle lanes to the advanced cycle stops (see fig. 7). This small measure has significant improved the cyclists safety on intersections with traffic lights (Rau, Haag, 2010).

8 PARKING RESTRICTION

Since 1990, the local council has implemented the concept of parking space management throughout the city centre. All public parking spaces cost money since that time. The principles of parking space management are:

- Downtown residents are entitled to park in public streets within a reasonable distance to their apartments in the form of a "parking permit solution."
- Regular long-stay parkers, above all employee commuters, are induced to switch over to other forms of transport by "tightening of the parking space screw."
- At the same time appropriate measures, as for example Park&Ride, are made available in the region to enhance the attraction of coming into the city by bus and tram rather than by car, especially to

bring customers and visitors into the city. This is important for Freiburg as a tourist city and a regional shopping centre.

- This is all designed to force long-stay parkers out of the city centre, which in the interest of Freiburg's economy and retail trade because the turnover frequency of the parking space is increased.

9 CONCLUSIONS

Transport policy must cover all areas of town planning and urban development with a comprehensive strategy. Town planning must ensure that as little avoidable traffic arises as possible. Above all, as it was already mentioned, Freiburg tries to apply these principles when planning new urban districts but also in giving priority to inner development before outer development of new houses and offices.

As a general principle, traffic avoidance strategies are to be taken into greater account in town planning. This means - in contrast to the failure of urban planning segregation concepts of past years - working and living must be integrated. Decentralized town planning of the new residential districts includes cultural and social activities, a multiplicity of shops and services as well as the pub round the corner and helps, of course, to avoid traffic.

General urban development policy, regional policy and traffic policy are interwoven intimately and must be considered as a whole unit. Housing policy and traffic policy must be seen as being interrelated. New housing clusters in the city and in the region should only be developed along the public transportation network axis. Urban development and traffic policy must be implemented unremittingly and with patience. Spectacular results in shifts within the modal split can only emerge after a moderate period of time.

Having a look at the modal split development between 1982 and 1999 indicates that we cannot only report on future intentions and projects, but in reviewing the years since 1976 we are already in a position to make a provisional appraisal and to record results in Freiburg. Overall this development in the modal split is very remarkable. Naturally, in Freiburg - as in Germany as a whole - the private car density has increased considerably. Consequently, the transport policy aims at having car owners drive a great deal fewer miles on the average. Drivers make much more frequent use of the green modes of rail, bus and bicycle. The city office hopes that this trend can continue.

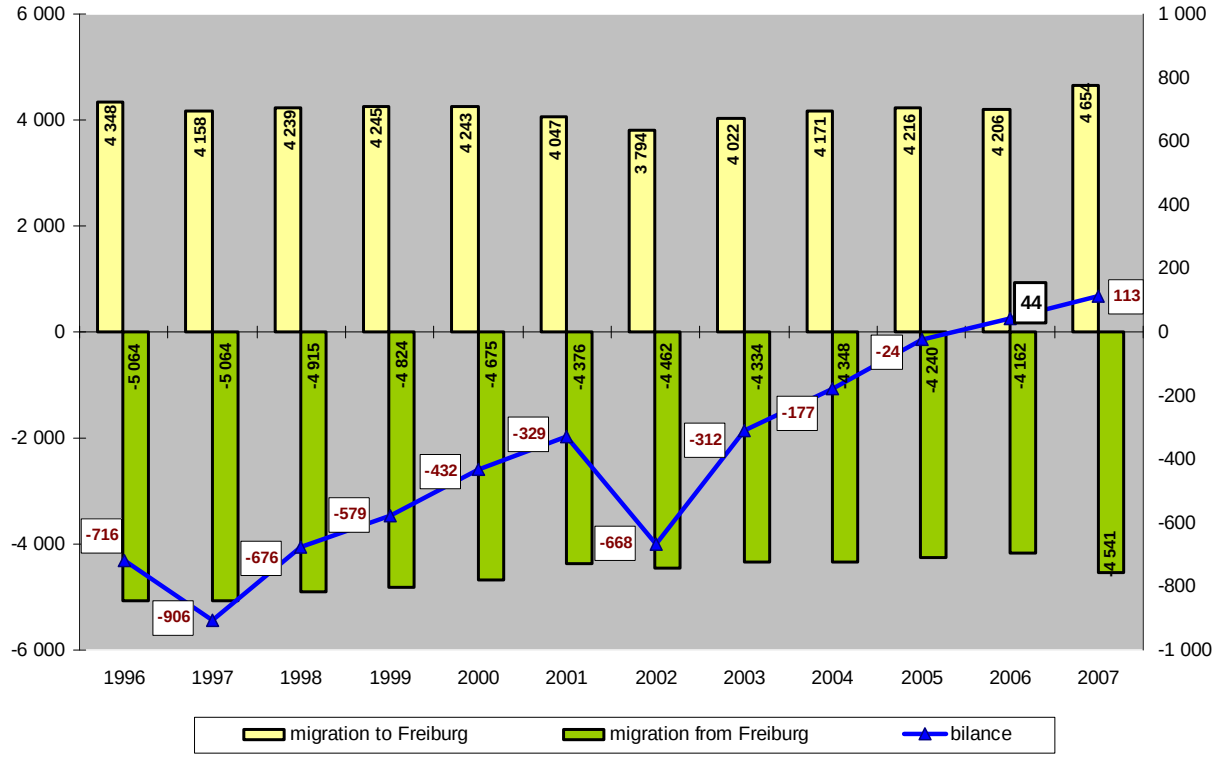

Fig. 8. Migration from Freiburg to neighbouring counties (Landkreis Breisgau-Hochschwarzwald and Landkreis Emmendingen) and from these counties to Freiburg in 1996-2007 (source: own compilation based on Amt für Bürgerservice und Informationsverarbeitung, Stadtamt Freiburg im Breisgau)

Consequent policy of urban renewal (first of all revitalization of old districts), modern concepts of new districts based on traditional neighbourhood design and sustainable transport development has achieved the success. In the last years more people have moved from suburban counties (Landkreis Breisgau-Hochschwarzwald and Landkreis Emmendingen) to the city than have migrated to suburbs. The reurbanisation has started.

1 ABSTRACT

The main focus of this paper has been to determine the functional regions in the heterogeneous area of Slovenia defined by integrated urban system at the (inter)national level. The notion of polycentric urban development is taken from the local and regional perspective based on the principle of proximity where co-operation, exchanges and networks among cities can contribute to the development of integrated urban systems to overcome the legacy of the inherited urban structures. Delineation of Slovenia into functional regions is based on labour market approach, where daily labour commuting has been considered as the main factor, which determines connectivity/relation between predefined local urban centres and municipalities in the functional regions. The urban centres of national and international importance in Slovenia have been determined mainly according to the number of inhabitants and their role in the polycentric urban system of Slovenia according to the Spatial Development Strategy of Slovenia (SPRS 2004).

2 INTRODUCTION

The main aim of sustainable spatial development policy of a country is balanced development of the whole territory, considering also sustainable development of wider area from the international perspective. European Spatial Development Perspective (ESDP 1999) defines three fundamental goals that should be achieved equally in all the EU regions. The goals are economic and social cohesion, conservation and management of natural resources and cultural heritage, and a more balanced competitiveness of the European territory. For achieving these goals the present state of regional development has to be studied as the base for further economic and political decisions. Each analysed territorial area should be based on complex, open, dynamic and nonlinear system that works on basis of functional connections between smaller and larger territorial areas. Region is in this way considered as a dynamic system that is very complex and difficult to manage from the administrative point of view. Because of that i.e. »functional region« is the most appropriate unit for economic analysis and for interaction of political, social and economic processes (Tomaney and Ward 2000).

Nowadays, the urban region/area has become the most essential functional level of urban and regional systems (Antikainen 2005). However, two main concepts have appeared: the concept of Functional Urban Area (FUA) and the concept of Functional Urban Region (FUR). These concepts are some of the means to study social and spatial disparities in different city centred (urban) areas, and related problems, such as residential segregation, outward diffusion of economic activities and people from urban cores or disparities in labour markets.

The European FUA concept focuses on categorizing dense built-up areas that form contiguous cores of urban areas, and commuters' belts; FUA is therefore a unit from which a fixed percentage of commuting to work is directed mainly within the area. The FUA limits are determined through percentages of commuters having their job in the core or in another FUA unit. For example, the project ESPON 1.1.1 (2004): Potentials for polycentric development in Europe considered functional urban areas, as travel-to-work areas of the main urban centres according to the common criteria implemented for approximately 1600 FUA in 29 European countries. Here, FUA consisted of an urban core and the surrounding area that was economically integrated with the centre, and represented the (sub)regional labour market area. In the countries with more than 10 million inhabitants, FUA was defined as having an urban core of at least 15,000 inhabitants and over 50,000 in total population. For smaller countries, FUA should had have an urban core of at least 15,000 inhabitants

and more than 0.5% of the national population, as well as having functions of national or regional importance.

Like the European FUA concept, the Functional Urban Region (FUR) concept reflects an urban definition and delimitation based on daily flows, in practice often commuting to work. It represents another attempt to capture the economic sphere of influence of a city with a core city defined in terms of concentrations of employment and a commuting hinterland composed of all those areas from which more people commute to the particular city in question than to some other city. In everyday language, FUR is probably best approximated by the term metropolitan area. However, the FUR concept is broader that FUA concept: they are more extensively defined than local labour markets or travel to work areas, because they impose no cut-off limits (such as 15 or 20 % of their resident population) on commuting. They are more urban, indeed metropolitan, because they do impose lower limits, of 15,000 – 20,000 jobs before counting a focal urban area as an urban core.

A Functional Region (FR) is a region characterised by a high frequency of intra-regional economic interaction, such as intra-regional trade in goods and services, labour commuting and household shopping patterns (Karlsson and Olsson 2006). From that sense, FR concept is much broader than FUR (or FUA) concept. The basic characteristic of a functional region is the integrated labour market, in which intra-regional commuting as well as intra-regional job search and search for labour is much more intensive than the inter-regional counterparts. The dominant concept in defining functional regions is that of (local) labour markets (Cörvers, Hensen and Bongaerts, 2009); that was illustrated by the substantial literature in this field by, for example, Andersen (2002), Coombes, Green and Openshaw (1986), Casado-Di´Az (2000), Eurostat (1992), and OECD (2002).

In some previous research (Drobne, Konjar and Lisec 2009; Konjar, Lisec and Drobne 2010), the methods to delimitate the functional regions using only data on commuters have already been analysed and discussed for Slovenia. Those methods have been already tested to define administrative regions of Slovenia as well (Drobne et al 2009). In this work labour market approach has been used to define functional regions in Slovenia using pre-defined centres of national and international importance of Slovenia – according to the (SPRS 2004) – as core centres for functional regions. For that purpose, we discuss first the polycentric urban and regional development concepts of Slovenia in Section 3. In Section 4, background of functional regions, materials and practical methodology for identifying functional regions using labour market approach are presented. Moreover, the functional regions in Slovenia are calculated using software developed by the authors of this paper.

3 POLYCENTRIC URBAN AND REGIONAL DEVELOPMENT CONCEPTS IN SLOVENIA

According to the implementation of the hierarchy of central places defined by Vrišer (1988), seven levels of central places were designed for spatial planning and regional policy purposes in Slovenia: local centres (1-4 lower level) and regional centres (5-7 higher level) in the Long-term Development Plan of Slovenia 1986-2000 adopted in 1986 as the comprehensive strategy for social, economic, spatial, regional and environmental development of the Republic of Slovenia within the former Yugoslav Federation. This development plan was formulated according to the concept of polycentric development considering specificities of different (geographical) areas (»planning regions«) and the network of regional and local centres (58 towns) with different population size and functions. The most important 12 regional centres were: Ljubljana, Maribor, Celje, Kranj, Novo mesto, Nova Gorica, Murska Sobota, Postojna, and several city clusters (conurbations) such as: Koper-Izola-Piran, Trbovje-Zagorje ob Savi-Hrastnik, Slovenj Gradec-Ravne na Koroškem-Dravograd, Krško-Brežice, Jesenice-Radovljica, with their gravitation areas (i.e. »planning regions«) covering the whole territory of Slovenia (see Fig. 1).

After independence of Slovenia in 1991 and the local government reforms since 1994 with transformation of former (larger) communes (62) to new small NUTS 5 municipalities (147-192-193-210-211, etc.), the urban hierarchy has been slightly transformed in the Spatial Development Strategy of Slovenia (SPRS 2004) defining »centres of (inter)national, regional, inter-municipal importance« – together 51 »urban centres« with 64 towns and other urban settlements, considering also urban conurbations (city clusters) at all levels. The most important regional centres (or the »centres of national importance«) in SPRS (2004) are: Ljubljana, Maribor, conurbation Koper-Izola-Piran, Celje, Kranj, Novo mesto, Nova Gorica, Murska Sobota, Velenje, Postojna, Ptuj, and conurbations: Slovenj Gradec-Ravne na Koroškem-Dravograd, Jesenice-Radovljica-

(Bled), Zagorje ob Savi-Trbovlje-Hrastnik, Krško-Brežice-(Sevnica) with their gravitation zones (i.e. 15 potential functional urban areas) that are not territorially specified and overlap between each other. Ljubljana, Maribor and conurbation Koper-Izola-Piran are also considered as »centres of international importance« due to their size, the status of a capital city of Ljubljana, the importance of the port of Koper in Central Europe, and geographical location of urban conurbation Koper-Izola-Piran near the borders with Italy and Croatia, and the second largest city of Maribor near the border with Austria, close to Hungary and Croatia (see Fig. 2).

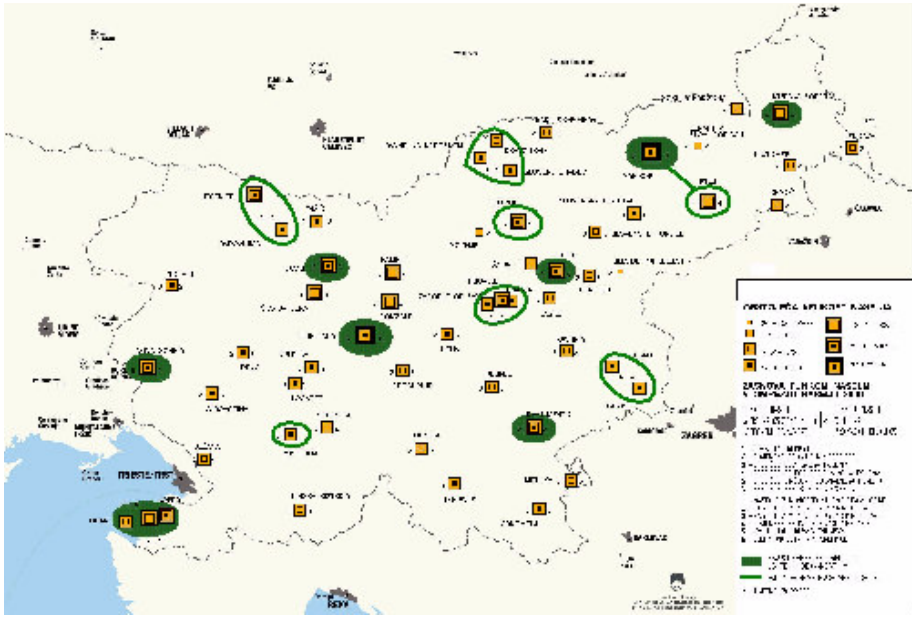

Fig. 1: Long term development plan of SRS 1986-2000 (1986): Urban network of 15 regional centres (denoted by green colour) and 43 local centres with city conurbations

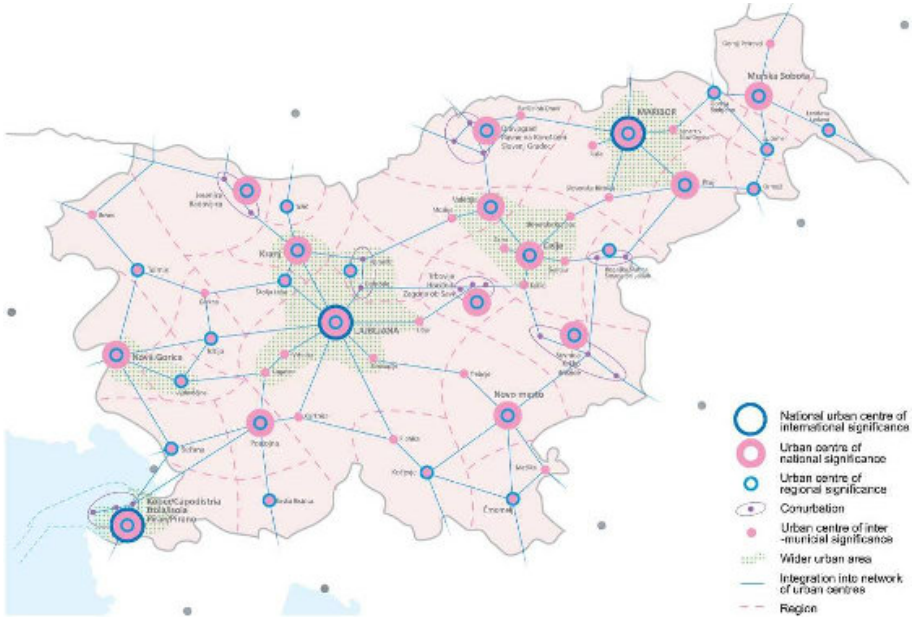

Fig. 2: Centres of (inter)national, regional and inter-municipal importance (regional and local centres) with city clusters, agglomerations and functional urban areas in the polycentric urban system of Slovenia (SPRS 2004)

Fig. 2 shows 51 »urban centres« of Slovenia (43 towns and 8 urban conurbations (21 towns and urban settlements) equals to 64 towns and urban settlements) defined by (SPRS 2004):

- 3 »centres of international importance«: Ljubljana, Maribor and Coastal conurbation (Koper-Izola-Piran);
- • 12 »centres of national importance«: 8 towns (Murska Sobota, Ptuj, Celje, Velenje, Kranj, Novo mesto, Postojna, Nova Gorica) and 4 urban conurbations (Jesenice-Radovljica-(Bled); Zagorje

ob Savi-Trbovlje-Hrastnik; Slovenj Gradec-Ravne na Koroškem-Dravograd; Brežice-Krško-(Sevnica);

- 16 »centres of regional importance«: 13 towns and 3 urban conurbations (Domžale-Kamnik; Šmarje pri Jelšah-Rogaška Slatina; Tržič-Bistrica);
- 20 »centres of inter-municipal importance«.

These 15 »centres of national importance« can be treated also as regional centres in Slovenia. Twelve of them are also centres of statistical NUTS 3 regions. Towns of Ptuj and Velenje were in 2008 proposed by the Government of RS as centres of two new administrative NUTS 3 provinces. Only one »centre of national importance« – city cluster (conurbation) Jesenice-Radovljica-(Bled) in Gorenjska statistical NUTS 3 region has not been officially proposed as the centre of new administrative NUTS 3 province.

In the polycentric development concepts from 1980s, the most important urban centres in Slovenia (e.g. regional centres) with their gravitation areas (planning regions) have been already highlighted. The new polycentric urban development concept (as before) emphasises the improved (equal) accessibility to public goods – administration, jobs, services and knowledge, that is located in these urban centres which are also important transportation nodes in Slovenia, and in Central Europe. Therefore polycentric development of (3-12-16-20) regional and local (urban) centres corresponds to the balanced regional development concept and development infrastructure along main European corridors V and X. During the preparation of the (revised) polycentric development concept in the Strategy of Spatial Development of Slovenia (SPRS 2004), the importance of urban agglomerations, city conurbations and their morphological and functional urban areas are being envisaged by the experts and policy makers, with potentials for cross-border cooperation taking in consideration improved cross-border mobility, accessibility, institutional links and networks, and cross-border, inter-regional and trans-national cooperation, and Slovenia's accession to the EU in year 2004.

3.1 Functional urban areas

Most jobs and economic activities in Slovenia are concentrated in the urban areas of Ljubljana, Maribor, Celje, Coastal conurbation Koper-Izola-Piran, followed by Kranj, Novo mesto, Velenje, Nova Gorica. Therefore travel-to-work migrations are the most intensive towards these cities. Most intensive commuting occurs in the gravitation areas of the largest employment (regional) centres such as Ljubljana, Kranj, Maribor, Celje, Velenje, Krško-Brežice, Koper-Izola-Piran, Novo mesto, Nova Gorica, Ptuj, Slovenj Gradec-Ravne na Koroškem, Murska Sobota. The Strategy of Spatial Development of Slovenia (SPRS 2004) promotes 15 »centers of national importance« (e.g. regional centres), including four city clusters, their gravitation and commuting zones as potential functional urban areas, even though they are not territorially defined. Twelve of these 15 centres of national importance are also centres of current 12 NUTS 3 (statistical or development) regions.

The project ESPON 1.1.1 (2004) considered functional urban areas (FUA) as travel-to-work areas of the main urban centres according to the common criteria implemented for approximately 1600 FUA in 29 European countries. The FUA consists of an urban core and the surrounding area that is economically integrated with the centre, and represents the (sub)regional labour market area. The analysis of FUA in Slovenia was prepared firstly according to the proposed methodology without any special modifications. As a result, six FUA of European importance were selected: Ljubljana (with Kranj), Maribor (with Ptuj), Celje (with Velenje), Novo mesto, Koper-Izola-Piran and Nova Gorica. According to the weighted results of ESPON 1.1.1. indicators (2004), Ljubljana FUA is the only urban area in Slovenia with the status of »weak« MEGA (Metropolitan European Growth Area) as one of 76 MEGAs in Europe. Due to the sea port function of international importance Koper-Izola-Piran FUA was given the status of transnational/national FUA while Maribor (with Ptuj), Celje (with Velenje), Novo mesto, Nova Gorica were identified as regional/local FUA.

Since it is important for Slovenia to be focused on small towns and middle-sized cities, and for the purpose of implementation of the INTERREG IIIB project PlaNet CenSE in Slovenia, the Ministry of Environment and Spatial Planning of RS (re)defined 10 FUA in 2006 having showed the most important regional centres – Ljubljana, Maribor, Koper-Izola-Piran, Celje, Kranj, Velenje, Novo mesto, Nova Gorica, Ptuj, Murska Sobota. Despite lower criteria for identification of other urban centres, the project did not take in consideration four city clusters of national importance (as one urban centre) with the common travel-to-work and gravitation areas. Therefore, it is more likely to talk about 15 FUA of European importance in Slovenia,

including MEGA Ljubljana, that are also important urban nodes in the polycentric and balanced development of Slovenia. Fig. 3 shows 10 FUA (re)defined in 2006 and marks 5 potential FUA (from top to bottom: Slovenj Gradec-Ravne na Koroškem-Dravograd; Jesenice-Radovljica-(Bled); Zagorje ob Savi-Trbovlje-Hrastnik; Brežice-Krško-(Sevnica); Postojna).

Most recently »Strategy for Regional Polycentric Urban System in Central-Eastern Europe Economic Integration Zone« (RePUS 2007) project implemented under the framework of the EU programme INTERREG IIIB CADSES addressed the problems of a more balanced, sustainable and polycentric urban system of middle-sized cities and small towns, that could strengthen emerging Potential Economic Integrating Zone (PEIZ) in Central and Eastern Europe. According to the RePUS methodology implemented in Austria, Italy, Hungary, Czech Republic, Hungary and Slovenia, 42 local functional urban areas (as local labour systems) and 17 regional functional urban areas (as regional labour systems) were identified in Slovenia (RePUS 2008); see Fig. 4.

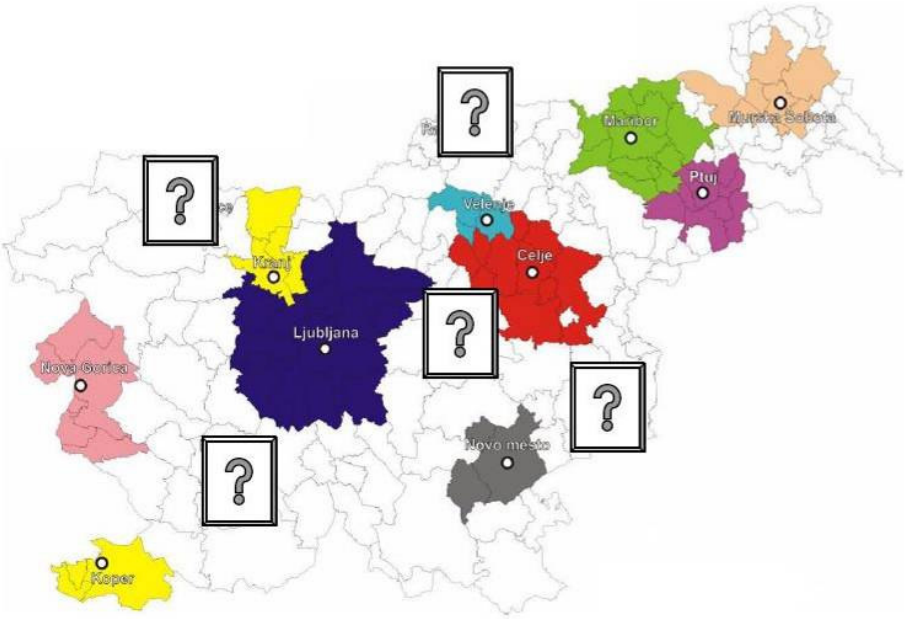

Fig. 3: Ten functional urban areas in Slovenia in 2006 (PlaNet CenSE 2006)

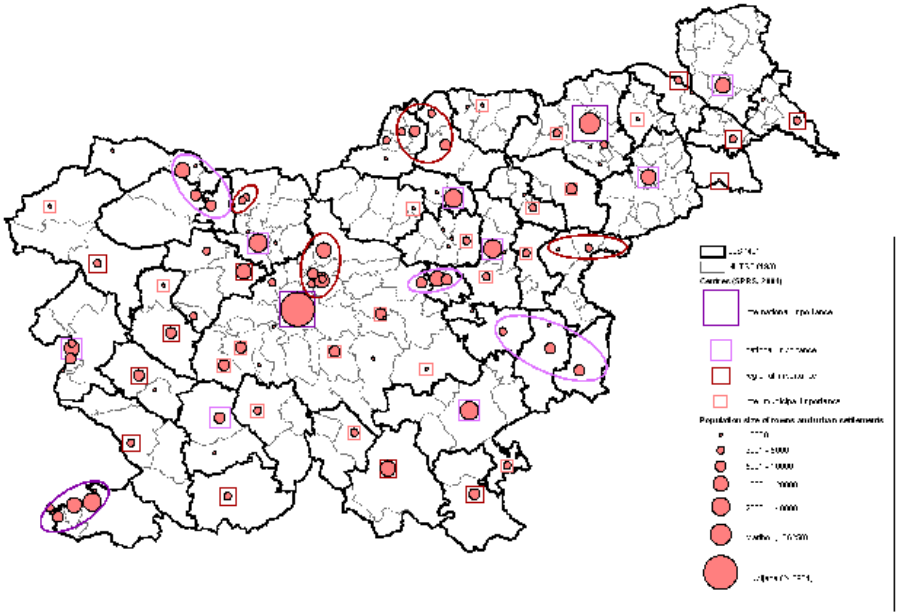

Fig. 4: Local and regional functional urban areas with urban network in Slovenia (RePUS, 2008)

4 FUNCTIONAL REGIONS

Functional region (FR) is the region defined by much more intense economic interactions inside the region than with any other area outside the region. A functional region is characterised by its agglomeration of

activities and by its intra-regional transport infrastructure, facilitating a large mobility of people, products, and inputs within its interaction borders.

In practise, two different concepts to delimit travel-to-work-areas are used: (a) delimitation around a centre, and (b) delimitation using algorithms or cluster analysis based on combination of distance, closeness, commuting thresholds, travel times, etc. It should be noted that certain centre-based definitions normally do not represent a division into regions or an exhaustive breakdown of the national territory but correspond to areas of extended urban influence; those portions of the national territory which lie outside this area of influence are all considered as rural areas. In delimitation based on centres, particular care needs to be taken in definition of these centres. While some countries identify centres according to the population or level of employment, others consider commuting conditions. In the latter case, the centre must be »self-sufficient«, which means that the number of workers living and working there is higher than the number of workers commuting to another centre, or it must attract a number of workers that is substantially higher than the number of workers leaving the centre to work outside.

4.1 Delimitation of functional regions using labour market approach

In our application of delimitation of functional regions, we used centre-based labour market approach that uses one-way commuter flows of inter-municipal working population. The model for delimitation of functional regions was described and discussed in (Drobne, Konjar and Lisec 2009), where centres had been defined by »functional approach« considering only data on commuters. Here, the municipalities were used as the smallest geographical areas to aggregate them into the functional regions. Data on inter-municipal commuting to work were acquired from Census 2002 (SORS 2009a). In 2002, there were a total of 287,272 inter-municipality commuters between 192 municipalities in Slovenia.

Urban centre			***Municipality***	
Rank	***Name***	***Population***	***Name***	***Population***
1	Ljubljana	268,423	Ljubljana	276,091
2	Maribor	96,408	Maribor	113,113
3	Koper-Izola-Piran-Lucija-Portorož	48,865 (24,658+11,317+4159+5793+2938)	Koper, Izola, Piran	84,638 (51,354+15,946+17,338)
4	Celje	38,047	Celje	48,991
5	Kranj	36,357	Kranj	54,188
6	Zagorje ob Savi-Trbovlje-Hrastnik	27,844 (6546+15,525+5773)	Zagorje ob Savi, Trbovlje, Hrastnik	44,750 (17,098+17,545+10,107)
7	Velenje	25,935	Velenje	33,226
8	Jesenice-Radovljica-Bled	24,715 (13,542+5924+5249)	Jesenice, Radovljica, Bled	48,674 (21,828+18,698+8148)
9	Novo mesto	22,874	Novo mesto	35,570
10	Ptuj	18,321	Ptuj	23,699
11	Brežice-Krško-Sevnica	18,374 (6558+7027+4789)	Brežice, Krško, Sevnica	67,487 (24,238+25,600+17,649)
12	Slovenj Gradec-Ravne na Koroškem-Dravograd	17,885 (7519+7030+3336)	Slovenj Gradec, Ravne na Koroškem, Dravograd	37,425 (16,662+11,722+9041)
13	Nova Gorica-Šempeter pri Gorici	16,810 (13,054+3756)	Nova Gorica, Šempeter-Vrtojba	38,250 (31,911+6339)
14	Murska Sobota	11,705	Murska Sobota	19,433
15	Postojna	8994	Postojna	15,455

Tab. 1: Urban centres of (inter)national importance (SPRS 2004) in municipalities and population on 1.1.2009 in Slovenia (SORS 2009b)

As a first stage of the applied methodology for delimitation of functional regions, municipalities that are strongly self-sufficient should be identified. In our application we used 15 centres of national and international importance defined in the Spatial Development Strategy of Slovenia (SPRS 2004), and already

indicated on Figs. 3 and 4. Tab. 1 shows 15 urban centres and urban conurbations of (intern)national importance in Slovenia (SPRS 2004) and the central (self-sufficient) municipalities that were applied in the labour market approach of delimitation of functional regions of Slovenia; note, that urban centre Šempeter pri Gorici has been included in a new urban agglomeration, together with Nova Gorica, due to very high percentage of commuters between them.

When self-sufficient municipalities, respectively groups of municipalities defined as urban conurbations, were defined, chains of municipalities from central (groups of) municipalities were created till condition (1) was satisfied:

$$\mathbf{FR}_i = \{x : f_i(x) \geq f_j(x)\}, \quad (1)$$

where $f_i(x)$ is the commuting frequency to the centre i at a location x, $f_i(x)$ is the commuting frequency to the centre j at a location x, and FR_i is the extension of the functional region i

$$(\mathbf{FR}_i = \{x : f_i(x) > 0\})$$

In practise, the chains of municipalities to the self-sufficient centres have been formed using bellow explained procedure. The chains have been calculated automatically using our own software based on Java platform, which considers the principle of maximum commuting flows for three types of municipalities: (a) the municipalities, that are directly connected with their maximum commuting flow of working population to the central municipality; (b) municipalities that are not directly connected with their maximum commuting flow to the central municipality, but they are connected with their maximum commuting flow to non self-sufficient municipality, which is than connected to the one of the central municipality; and (c) the pairs of municipalities, which present to each other the destination of the maximum flows, have been connected to the region, in which the direction of the second maximum flow was oriented.

Fig. 5 shows three functional regions defined by two urban centres and one urban conurbations of international importance at the NUTS 2 level, and Fig. 6 shows fifteen functional regions defined by nine urban centres and six urban conurbations of national importance in Slovenia at the NUTS 3 level.

From Fig. 5, the huge functional influence of the capital of Slovenia, i.e. Ljubljana, is evident at the NUTS 2 level. In the case of three functional regions, functional region of Ljubljana cover 78 % of the country (!). That is also the result of ESPON 1.1.1. (2004), where Ljubljana FUA is the only one urban area in Slovenia with the status of »weak« MEGA (Metropolitan European Growth Area) as one of 76 MEGAs in Europe (see also Fig. 7).

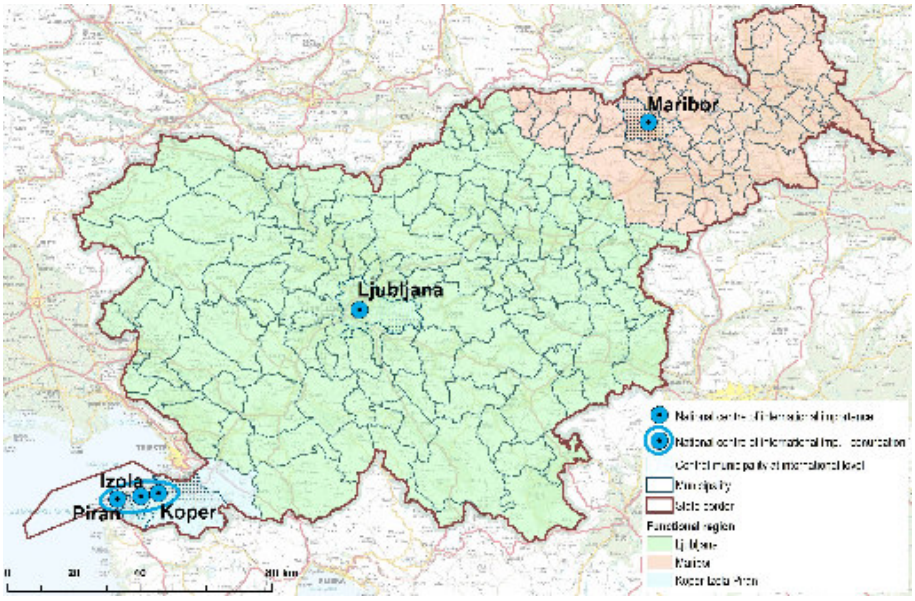

Fig. 5: Three functional regions defined by two urban centres and one urban conurbations of international importance in Slovenia

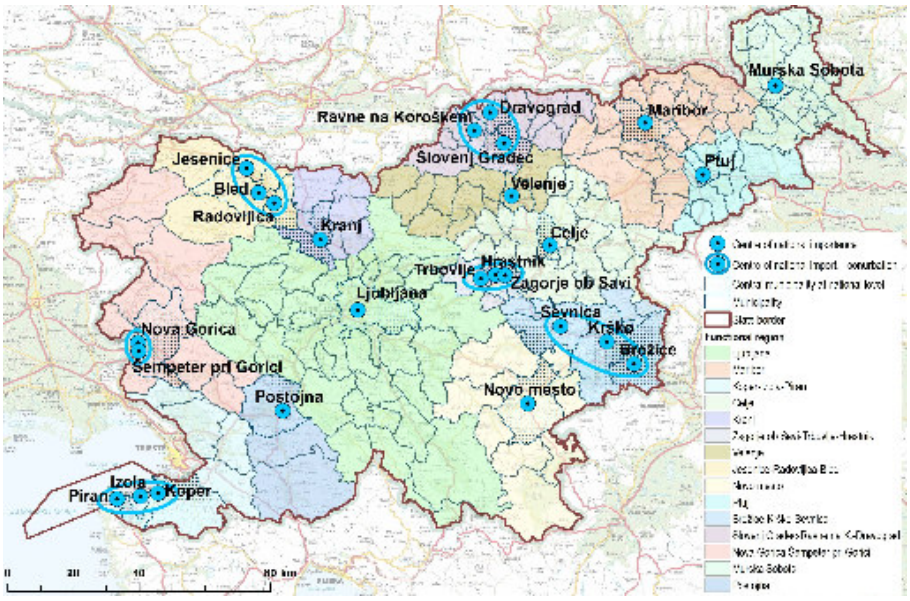

Fig. 6: Fifteen functional regions defined by nine urban centres and six urban conurbations of national importance in Slovenia

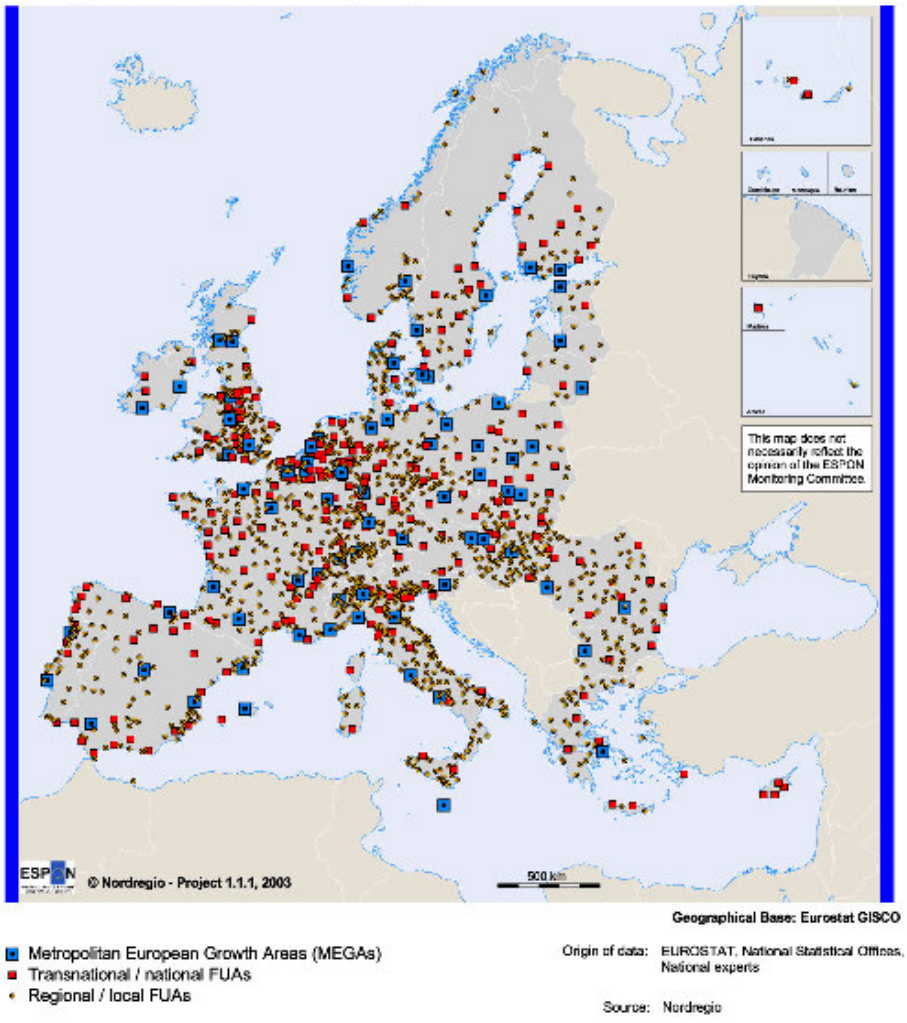

Fig. 7: Typology of functional urban areas (FUAs) in Europe (ESPON 2004)

Tab. 2 and 3 show some basic characteristics of functional regions at NUTS 2 and NUTS 3 level in Slovenia. At both level, functional region Ljubljana has the highest population. Discrepancy between functional regions at NUTS 2 level is obvious: urban conurbation Koper-Izola-Piran can not compete with functional region Ljubljana at all: there is almost 17-times less population in the smallest FR (Koper-Izola-Piran) than in the largest FR (Ljubljana) at NUTS 2 level of Slovenia!

This proportion remains the same at the NUTS 3 level (between Postojna and Ljubljana) – but with the exception of Ljubljana (and Maribor) other functional regions are more comparable at the NUTS 3 level. The average functional region at NUTS 3 level has population of almost 135,490 inhabitants (without Ljubljana 100,340 inhabitants).

Delimitation of functional regions around the urban centres and urban conurbations at NUTS 3 level in Slovenia has re-arranged the relative importance of functional connections in the (functional) region. Ranks of the importance (according to the population in the analysed entities) are not same for urban centres (and conurbations) and for functional regions (compare Tab. 1 and Tab. 3). Comparing the relative importance of functional regions to relative importance of urban centres (conurbations), there are five functional regions that have higher relative importance than their urban centres (including urban conurbations); those are Celje, Novo mesto, Nova Gorica-Šempeter pri Gorici, Murska Sobota and Brežice-Krško-Sevnica. Five functional regions with lower relative importance than their urban centres (conurbations) are Koper-Izola-Piran-Lucija-Portorož, Kranj, Velenje, Jesenice-Radovljica-Bled and Zagorje ob Savi-Trbovlje-Hrastnik. And, five functional regions of Ljubljana, Maribor, Ptuj, Slovenj Gradec-Ravne na Koroškem-Dravograd and Postojna have the same relative importance than their urban centres (conurbations).

Rank	***Functional region***	***Population***		***Number of municipalities***
		Number	***%***	
1	Ljubljana	1,488,805	73,2 %	134
2	Maribor	454,793	22,4 %	72
3	Koper-Izola-Piran	88,764	4,4 %	4
	Slovenia	***2,032,362***	***100,0 %***	***210***

Tab. 2: Population and number of municipalities in functional regions at NUTS 2 level in Slovenia

Rank	***Functional region***	***Population***		***Number of municipalities***
		Number	***%***	
1	Ljubljana	627,565	30,9 %	41
2	Maribor	265,423	13,1 %	28
3	Celje	190,423	9,4 %	20
4	Novo mesto	110,081	5,4 %	14
5	Koper-Izola-Piran	108,778	5,4 %	7
6	Nova Gorica-Šempeter pri Gorici	101,908	5,0 %	11
7	Murska Sobota	99,237	4,9 %	23
8	Kranj	93,920	4,6 %	7
9	Brežice-Krško-Sevnica	79,075	3,9 %	7
10	Ptuj	73,859	3,6 %	16
11	Velenje	67,868	3,3 %	12
12	Slovenj Gradec-Ravne na Koroškem-Dravograd	67,778	3,3 %	11
13	Jesenice-Radovljica-Bled	66,368	3,3 %	7
14	Zagorje ob Savi-Trbovlje-Hrastnik	44,750	2,2 %	3
15	Postojna	35,329	1,7 %	3
	Slovenia	***2,032,362***	***100,0 %***	***210***

Tab. 3: Population and number of municipalities in functional regions at NUTS 3 level in Slovenia

5 CONCLUSION

The ESPON 1.1.1 project (2004) found that Slovenia is one of the most polycentric European countries despite the small size of the country. This is a direct consequence of polycentric spatial and regional development policies since the end of 1960s. Polycentric development concept and distribution of jobs, services and financial subsidies have been also an instrument of balanced regional development policy in Slovenia, which was (partly) modified only by the local development (communal) policy in 1970s, and market reforms in 1990s. During 1990s the polycentrism has been in the shadow of centralisation tendencies and macro-economic priorities of Slovenia, as the new independent country, and the incomplete local government reforms. But the polycentric development concept has been present again since year 2000 in the most important new strategic development documents, such as the economic policy, regional policy, and spatial development policy, that are also complementary with the goals of the EU policy documents, looking over polycentrism as the main principle that guarantees effective, moderate and balanced spatial development (Zavodnik Lamovšek, Drobne and Pichler Milanović 2009).

In the paper, we discussed polycentric urban and regional development concepts in Slovenia which results defined urban centres of international and national importance in Slovenia (SPRS 2004). Using those, pre-

defined, centres of national and international importance of Slovenia as core centres and labour market approach, we defined functional regions in Slovenia. Functional regions have been analysed at NUTS 2 and NUTS 3 levels. As showed by other authors before, the daily interaction in the labour market can be considered as a good approximation for the functional region. In this way, delineation of functional regions can be used as a good starting point and framework for further analyses and research.

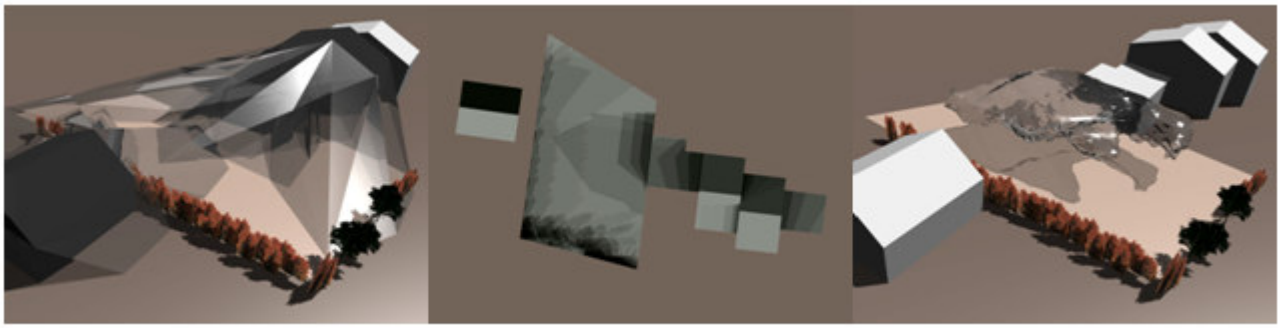
Generative Solar Design. Lichträume, Schattenkörper und dynamische Sonnenstandssimulation mit Open-Source-Software

Wolfgang Höhl

(Prof. Dr.-Ing. Wolfgang Höhl, Munich University of Applied Sciences, whoehl@hm.edu)



Schattenkörper, Bauplatzverschattung und maximal besonntes Volumen als generativer Entwurf. Renderings © 2009 Wolfgang Höhl

1 ABSTRACT

Wenn das Sonnenlicht selbständig Räume gestalten könnte - wie könnten sie aussehen? Wären es amorphe Lichträume und fließende Schattenkörper? Die dynamische Sonnenstands- und Fluidsimulation mit Open-Source Software zeigt neue Wege der intelligenten Tageslichtplanung.

Die Thematik ist nicht neu. Räumlich-grafische Verfahren zur Tageslichtplanung gehören seit langem zum Repertoire moderner Architektur. Neu sind hingegen die Möglichkeiten, diese Verfahren mit freier Software zu interpretieren und im generativen Architekturentwurf zu nutzen.

Dieser Beitrag beschäftigt sich mit der Umsetzung räumlich-grafischer Verfahren zur Sonnenstandssimulation mit den freien Softwarepaketen Blender 2.48a und GIMP 2.6.2. Angewendet wird dabei ein Mix von drei verschiedenen Techniken: Scripting mit Python, Texture Baking und dynamische Fluidsimulation.

In den ersten vier Abschnitten werden folgende Fragen behandelt: Welche Hardware und Software brauche ich? Welche Verfahren zur Tageslichtplanung gibt es? Wie funktioniert ein Setup für 'Generative Solar Design' mit Open-Source Software? Wie lassen sich die Baumassen nach Besonnung und Verschattung optimieren? Am Beispiel eines realen Bauplatzes werden konkrete Lösungsansätze formuliert. Eine abschließende Zusammenfassung zeigt weitere interessante Forschungsansätze und Perspektiven.

Diese neuen technischen Möglichkeiten sollen anregen, selbst mit Open Source Software zu experimentieren!

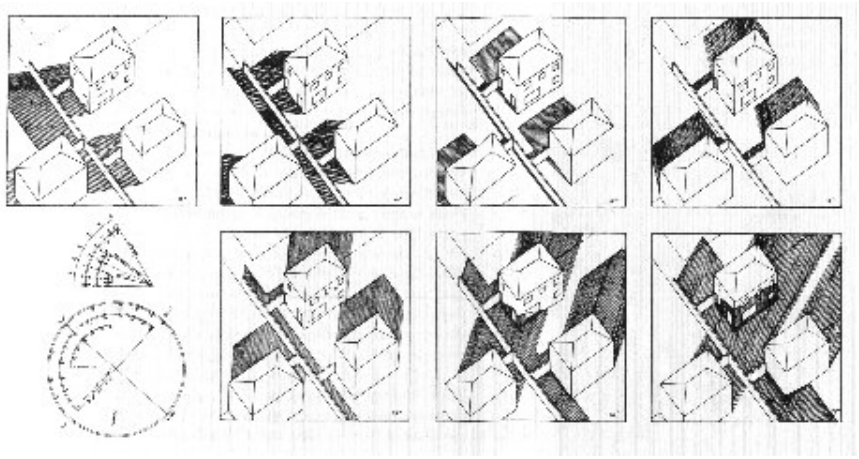
2 WELCHE HARDWARE UND SOFTWARE BRAUCHE ICH?

Alle Ergebnisse in dieser Arbeit wurden mit nachfolgend angegebener Hard- und Softwarekonfiguration erzielt. Denkbar wären aber auch andere Betriebssysteme, wie Microsoft Windows XP oder MacOS, oder ähnlich leistungsfähige Hardware.

Software	Blender 2.48 a GIMP 2.6.2 Yaf(a)ray 0.1.0 (optional)
Pythonscripts	sun_gui-D.py quantitybill.py
Betriebssystem	Ubuntu 8.10 (Intrepid Ibex) Kernel Linux 2.6.27-11-generic GNOME 2.24.1
Hardware	Hewlett Packard HP 6735 b
Prozessor	AMD Turion X2 Dual Core Mobile RM-72
Arbeitsspeicher	2048 MB RAM
Grafikkarte	512 MB ATI HD 3200
Harddisk	250 GB
Anzeigesystem	15,4“ WXGA Widescreen matt

3 WELCHE VERFAHREN ZUR TAGESLICHTPLANUNG GIBT ES?

Licht, Luft, Sonne! Das waren, unter anderen, die drei zentralen Forderungen der klassischen Moderne. Es gibt bis heute mehrere gebräuchliche Verfahren zur Tageslichtplanung und sehr viele hervorragende realisierte Beispiele zum solar optimierten Architekturentwurf. HAAS-ARNDT und RANFT [2007] nennen sieben Verfahren zur professionellen Tageslichtplanung: rechnerische Verfahren, grafische Schattenkonstruktionen, die grafische Bestimmung des Tageslichtquotienten, Messungen mit Horizontoscop und Sonnenstandsdiagramm, Simulationen am realen Modell, Computersimulationen und die fotometrische und physikalische Lichtmessung. Betrachtet werden in diesem Beitrag lediglich grafische Schattenkonstruktionen, Messungen mit dem Horizontoscop und Computersimulationen.



Grafische Besonnungsanalysen von Alexander Klein. Aus: KLEIN, Alexander: Der Südtyp: Das Einfamilienhaus mit Südorientierung, Stuttgart 1934, in: OSWALT, Philipp, REXROTH, Susanne (Hrsg.): Wohltemperierte Architektur – Neue Techniken des energiesparenden Bauens, Verlag C. F. Müller, Heidelberg 1995, S. 53

Schon um 1931 entwickelte Alexander Klein, neben anderen Analysemethoden, ein grafisches Verfahren zur Bestimmung der Besonnung im Tages- und Jahresverlauf. Es ermöglichte ihm, verschiedene Grundrissvarianten besser zu beurteilen und eine optimal besonnte Alternative auszuwählen. 1934 erscheint sein Buch „Der Südtyp: Das Einfamilienhaus mit Südorientierung“.

„In diesem Buch formuliert er die wesentlichen, noch heute gültigen Prinzipien des solaren Bauens – Südorientierung, Zonierung in unterschiedlich temperierte Bereiche, Maximierung der sonnenzugewandten Flächen und Minimierung der Aussenoberfläche zur Vermeidung von Wärmeverlusten.“ [OSWALT 1995]

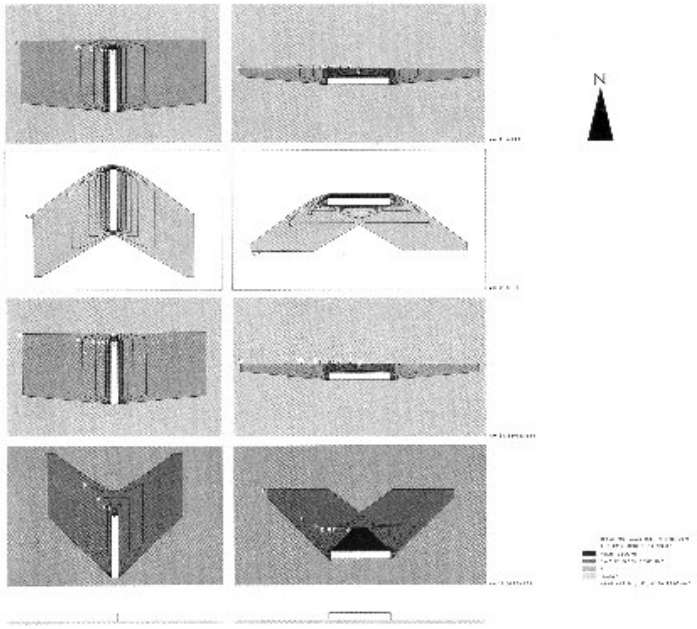
Konsequent gestaltet er seinen Gebäudeentwurf nach den Erkenntnissen seiner Besonnungs- und Verschattungsanalysen. Auch für Roland Rainer war die Besonnung immer ein zentrales Planungselement. Er nutzte grafische Schattenkonstruktionen zum Beispiel zur Darstellung der Besonnungszeiten eines Grundstücks abhängig von der Orientierung der Gebäudezeile.

Hannes Meyer verdeutlicht diesen interessanten Planungsansatz in seinen Thesen:

„ ... wir errechnen die sonneneinfallswinkel im jahreslauf und bezogen auf den breitengrad des baugeländes, und wir konstruieren danach den schattenfächer des hauses im garten und den sonnenlichtfächer des fensters im schlafzimmer. Wir errechnen die tageslichtbeleuchtung der arbeitsfläche im innenraum, ... : der hauskörper ist bei uns ein akkumulator der sonnenwärme. ...“ [CONRADS 1981]

1952 gründete der Architekt Friedrich Tonne das Institut für Tageslichttechnik in Stuttgart und entwickelte das Horizontoscop. Das Horizontoscop ist ein grafisch-optisches Instrument zur Bestimmung der Dauer der Besonnung beziehungsweise der Verschattung von vorgegebenen Orten. Es unterstützt die Tageslichtplanung bei Neubauten und Verbesserungen bei bestehenden Gebäuden. Stereografische Sonnenstandsdiagramme erlauben die Bestimmung der Sonnenstandsposition für jeden beliebigen Zeitpunkt für einen konkret vorgegebenen Ort. Über ein fotografisches Verfahren kann die Dauer der Besonnung und der Verschattung von konkreten Orten bestimmt werden.Der Vorteil des Instruments liegt in seinem relativ einfachen Setup und seiner guten Nutzbarkeit im Innen- und im Aussenraum. [BORN 2006]

Auch die japanische Baugesetzgebung nutzt räumlich-grafische Verfahren im Baugenehmigungsverfahren. Die sogenannte „Set-Back-Line“ regelt die Baukörperform nach Besonnung und Verschattung in dicht bebauten Gebieten.

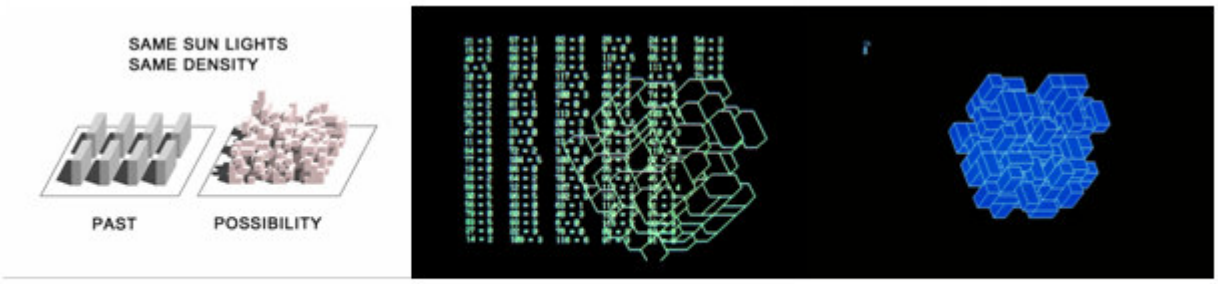


Besonnungszeiten in Stunden, Gebäudezeilen in unterschiedlicher Orientierung, in: RAINER, Roland: Vitale Urbanität - Wohnkultur und Stadtentwicklung, Böhlau Verlag, Wien 1995, S. 54

Horizontoscop und Sonnenstandsdiagramm . © 2009 Institut für Tageslichtechnik, Stuttgart

Der japanische Architekt Makoto Sei Watanabe entwickelte eines der ersten generativen Verfahren für den Architekturentwurf. Das Sonnenlicht moduliert dabei Form und Dichte der Bebauung. Ab 1995 entstanden

die generativen Computermodelle der „City of the Sun God“ und der „Sun God City 2“. [WATANABE 2002]



City of the Sun God . Studien © 1995 - 2009 MAKOTO SEI WATANABE RCHITECTS' OFFICE , Tokyo/Japan

1996 präsentiert Ernst J. Fuchs (the next ENTERprise – architects, Wien) einen der ersten computergestützten, autokatalytischen Architekturentwürfe. Für ein Grundstück in Zirl/Tirol entwickelt er aus der konkreten Besonnungssituation eine räumliche Struktur für ein Einfamilienhaus. Wie ein „räumliches Datenfeld“ initiieren Verschattung und Besonnung einen generativen Prozess, der die finale Gebäudeform entwickelt. Nach einigen automatisierten Programmschleifen entwickelt sich ein vielfältig gegliedertes Gebäude auf hohen Stützpfeilern über dem Bauplatz. [HÖHL 1999]

4 'GENERATIVE SOLAR DESIGN' – DIGITAL MOCKUP MIT OPEN-SOURCE SOFTWARE?

Blender bietet viele Möglichkeiten für die Architekturvisualisierung. Mit Blender sind nicht nur klassische Visualisierungen und Animationen möglich. Auch komplexe interaktive 3D-Walk-Throughs und einfache Games können Sie mit Blender sehr unkompliziert gestalten.

Mit vielen, so genannten Pythonscripts können Sie den herkömmlichen Funktionsumfang von Blender sehr rasch erweitern. Für ein generatives Setup zur solaren Gestaltung brauchen Sie zwei zusätzliche Skripte: eines zur Sonnenstandssimulation (sun_gui-D.py) und ein weiteres, um Flächen und Volumina messen und festhalten zu können (quantitybill.py). Sie finden diese Skripte in den Foren von www.blender.org. Der Gebrauch der 3D-Software Blender ist relativ komfortabel. Blender steht als freies Softwarepaket zum Download für die gebräuchlichsten Betriebssysteme zur Verfügung.

In Blender lassen sich beliebigee 3D-Baumassenmodelle aus Ihrer standardmäßigen Architekturanwendung importieren. Laden Sie das Pythonscript sun_gui-D.py Ihrer Blenderdatei hinzu und folgen Sie im Setup den Anweisungen des genannten Pythonscripts. Damit hätten Sie die Grundbestandteile für ein Solar Setup schon beisammen. Wenn Sie nun eine bestimmte Tageszeit eingeben, können Sie mit dem Animationsbutton jeden Sonnenstand zu jedem beliebigen Ort und zu jeder Zeit auf der Welt simulieren. Ein wertvoller link im Pythonscript hilft Ihnen, den korrekten Längen- und Breitengrad zu bestimmen. Sie können das Ergebnis über den internen Renderer oder auch über Yaf(a)ray als Bild ausgeben.

Der generative Architekturentwurf ist eine offene, zyklische Optimierungsschleife. Sie schaffen technische Rahmenbedingungen und generieren danach verschiedene Formen. Aus der ersten Generation dieser Formen wird die am meisten geeignete ausgewählt und weiterentwickelt, indem die Optmierungsschleife wiederholt wird. Wie sieht das nun konkret aus?

5 WIE LASSEN SICH DIE BAUMASSEN NACH DER BESONNUNG OPTIMIEREN?

Zunächst wird der maximale Raum festgelegt, in dem sich der Entwurf entwickeln kann. Danach können automatisch Formen generiert werden. Diese Formen können nach Besonnung, Verschattung oder anderen sinnvollen Kriterien (z.B.: dem Verhältnis von Oberfläche zu Volumen) bewertet und ausgewählt werden, dann wiederholt sich die Prozedur, bis die optimale Form gefunden ist. Dieser Prozeß wird im Folgenden in zehn Schritten dargestellt:

- Darstellen der Situation . Nachbargebäude und Bepflanzung
- Berechnen der Verschattung des Grundstücks

- Modellieren der Schattenkörper
- Festlegen des Umfangs der Bebaubarkeit
- Darstellen von Baumasse, Baugrenze und maximalem Lichtraum
- Generativer Entwurf innerhalb der optimal besonnten Baumasse
- Formtypen, Auswahl und Weiterentwicklung der besten Form
- Neuerliche Prüfung von Verschattung und Besonnung
- Remodeling von Schattenkörper und Baumasse
- Wiederholung der Optimierungsschleife bis zum finalen Rendering

6 OPTIMIERUNG DER BEBAUUNG NACH BESONNUNG UND VERSCHATTUNG

6.1 Darstellen der Situation . Nachbargebäude und Bepflanzung

Wie dieser Prozess funktioniert, wird an dem nun folgenden Beispiel demonstriert. Der konkrete Bauplatz befindet sich nahe am Starnberger See, zirka 30 km südwestlich von München. Das Grundstück liegt am Rande einer dörflich gewachsenen Siedlungsstruktur. Die Umgebung besteht aus Einfamilienhäusern, gebaut in den letzten vier Jahrzehnten. Das Grundstück ähnelt einer langgestreckten Raute. Die längeren Seiten liegen nach Westen und Osten. An diesen beiden Seiten schließen auch die Nachbargrundstücke mit ihrer Bebauung oder zum Teil mit hohen Hecken an. An der kurzen Nordseite liegt die Erschließungsstraße, Nach Süden grenzen einige Bäume und Büsche das Grundstück von einer anderen Anliegerstrasse ab

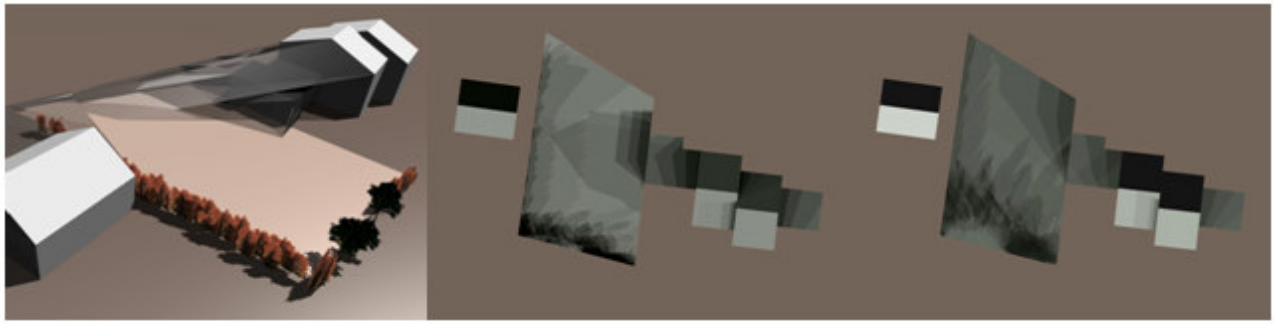
Situation mit Nachbargebäuden und Bepflanzung . Renderings © 2009 Wolfgang Höhl, München

6.2 Berechnen der Verschattung des Grundstücks

Die Verschattung des Grundstücks (stündlich von z.B.: 06:00 – 18:00 Uhr) wird zu drei verschiedenen Terminen berechnet: 22.06. (Sommer), 21.03./23.09. (Frühling/Herbst) und 22.12. (Winter). Dafür werden drei neue Blenderdateien erstellt. Im Dialogfeld des Pythonscripts sun_gui-D.py können anschließend die Werte entsprechend eingestellt werden. Wenn man die Dateien getrennt voneinander speichert, kann man nun eine Datei nach der anderen öffnen, und die Verschattung zu jedem konkreten Termin berechnen lassen.

Dabei wird stundenweise vorgegangen. Jeder Schattenverlauf wird mit ‚Texture Bake' auf das Grundstückspolygon ‚gebacken'. Sie erhalten so zu jedem der drei Termine 13 Bilder als Texture Bakes vom Grundstück. Diese Bilder können in einem Standardgrafikformat exportiert werden. Mit einem geeigneten Bildbearbeitungsprogramm (z.B.: GIMP) werden diese Texture Bakes als Ebenen aufeinandergelegt und zu einem Gesamttagesbild verschmolzen. Anschließend kann dieses Gesamttagesbild wieder auf Ihr Grundstück in Ihrer Blenderdatei projiziert werden. Damit erhalten Sie drei Schattenbilder für die entscheidenden Schlüsseltermine im Frühjahr/Herbst, Sommer und Winter.

Danach können die zugehörigen Schattenkörper zu jedem Termin modelliert werden.

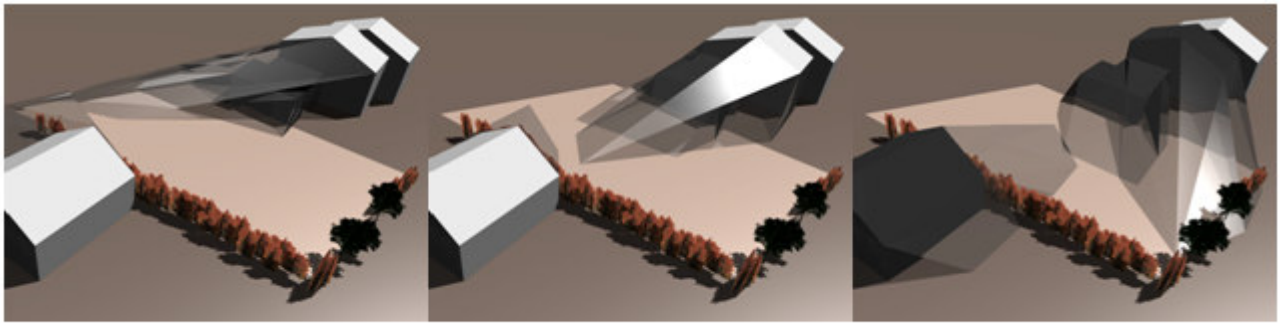


Verschattung des Grundstücks am 22. Juni (Sommer), am 21. März/23. September (Frühling/Herbst) und am 22. Dezember (Winter). Renderings © 2009 Wolfgang Höhl, München

6.3 Modellieren der Schattenkörper

Mit einer geeigneten Modellierungstechnik (z.B.: Face Extrude, Poly-by-Poly Modeling), können nun die Schattenkörper nach dem vorgegebenen Umgebungsmodell und den zugehörigen Schattenbildern modelliert werden.

Das kann einige Zeit in Anspruch nehmen. Der Aufwand lohnt sich aber.

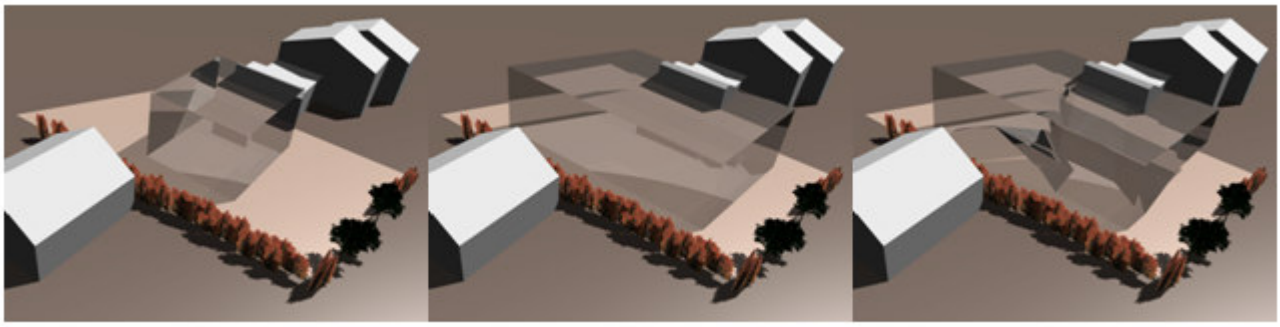


Modellieren der Schattenkörper nach Umgebung und Schattenbild . Renderings © 2009 Wolfgang Höhl, München

6.4 Festlegen des Umfangs der Bebaubarkeit

Als nächstes wird das Maß der baulichen Nutzung bestimmt.

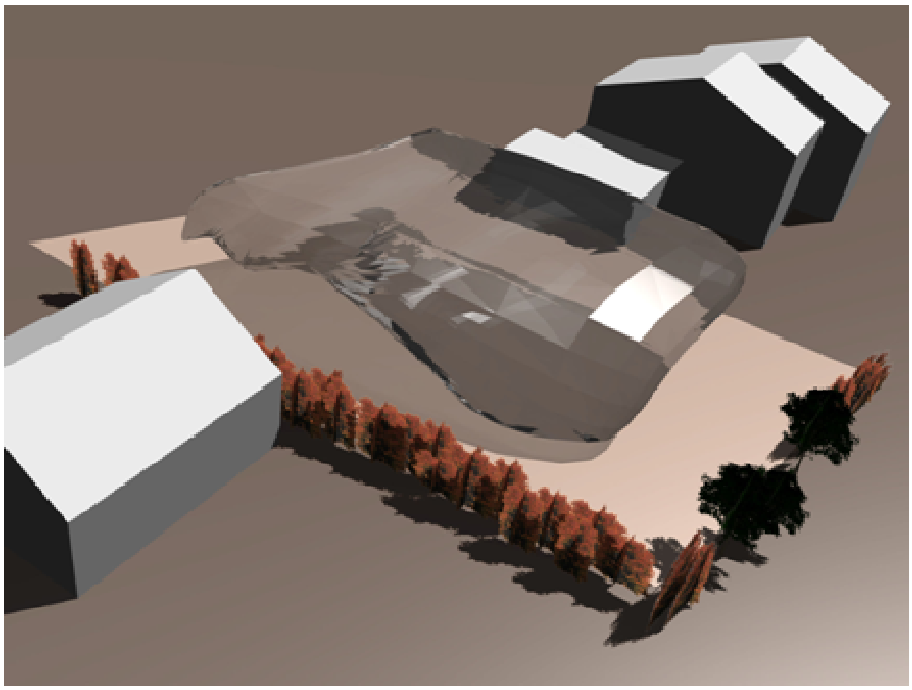
Grundstücksgröße	604,25 m²
Geschossflächenzahl (GFZ)	0,30
Maß der baulichen Nutzung	**181,28 m²**
Grundflächenzahl (GRZ)	0,20
Maximal zulässige Grundfläche	**120,85 m²**
Bruttogeschosshöhe	3,50 m
Maximale Gebäudehöhe (2 Geschosse)	7,00 m
Maximal zulässiges Volumen	**634,48 m³**



(1) Maximal zulässiges Volumen nach GFZ und GRZ = 634,48 m³. (2) Maximales Volumen nach Abstandsflächen = 1934, 03 m³. (3) Maximales Volumen abzüglich Schattenkörper = 1490.94 m³. Renderings . © 2009 Wolfgang Höhl, München

6.5 Darstellen von Baumasse, Baugrenze und maximalem Lichtraum

Der kleine Quader im ersten Bild entspricht dem maximal zulässigen Volumen von 634,48 m² auf der maximal zulässigen Grundfläche von 120,85 m². Das zweite Bild stellt das größtmögliche Volumen über der maximal bebaubaren Fläche unter Berücksichtigung der notwendigen Abstandsflächen dar. Dieses größtmögliche Volumen nach Abstandsflächen wird nun mit den konstruierten Schattenkörpern verschnitten. Der Restkörper, den Sie dadurch erhalten, ergibt den größtmöglichen Umraum, in dem sich der generative Entwurf nun entfalten kann (maximaler Lichtraum). Das Volumen beträgt 1.490,94 m³. Dieser maximale Lichtraum kann so modifiziert werden, daß im Endergebnis ein optimales Verhältnis von Oberfläche zu Volumen besteht. Dazu eignet sich, zum Beispiel, ein ‚Subsurf Modifier'. Das optimierte Volumen nach dieser Prozedur beträgt nun 1.066,03 m³. Das ist das Volumen, in dem sich der generative Entwurf nun entwickeln kann. Im nächsten Schritt wird das Volumen des optimierten maximalen Lichtraumes mit ‚Flüssigkeit' gefüllt



Optimierter maximaler Lichtraum = 1066.03 m³ . Rendering © 2009 Wolfgang Höhl, München

6.6 Generativer Entwurf innerhalb der optimal besonnten Baumasse

Mit diesem Verfahren ist es möglich, endgültige Lage und die Form des Baukörpers zu bestimmen. Füllen Sie dazu den optimierten maximalen Lichtraum mit ‚Flüssigkeit'. Das mögliche Füllungsvolumen beträgt, nach der oben geführten Rechnung, maximal 635 m³.

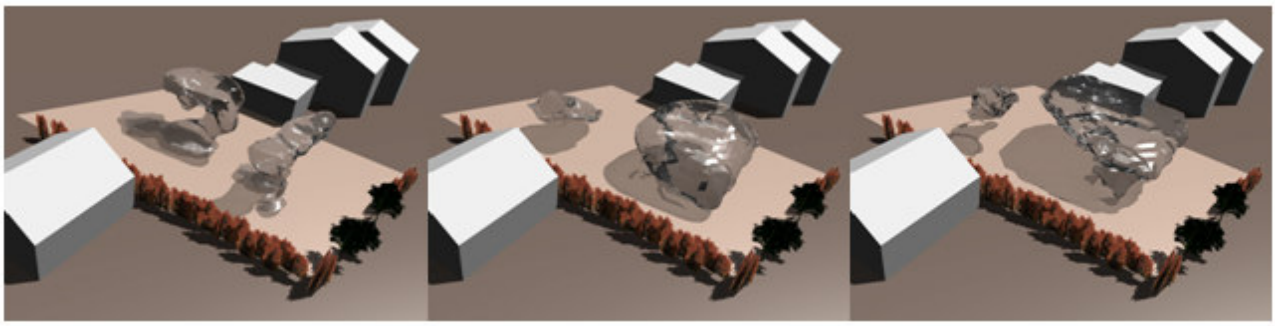
Die Werkzeuge zur Fluidsimulation bieten eine Menge an Variablen und Einstellungsmöglichkeiten. Hier ist es notwendig, eine geeignete Konfiguration zu finden und auszuwählen, um den optimierten maximalen

Lichtraum zu füllen. Verschiedenen Setups geben eine Fülle an Möglichkeiten zu experimentieren und auf diese Weise die unterschiedlichsten Formen zu erzeugen.

6.7 Formtypen, Auswahl und Weiterentwicklung der besten Form

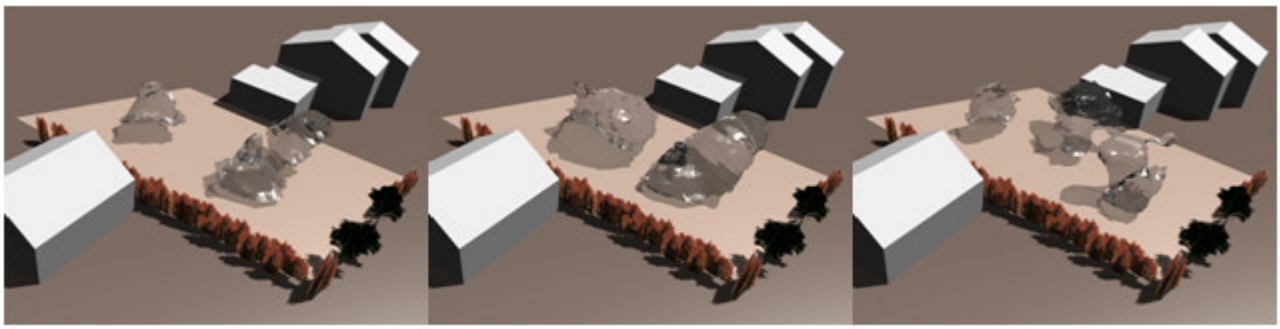
Abhängig von der experimentellen Anordnung können nun verschiedene Formtypen entstehen: In diesem Fall entwickelten sich „Quellen“, „Säulen“ und „Wolkenbügel“. Diese Formen sollten nun nach geeigneten Kriterien (z. B. nach der Verschattung) geprüft und die am meisten geeignete Form ausgewählt werden..

„Quellen“:



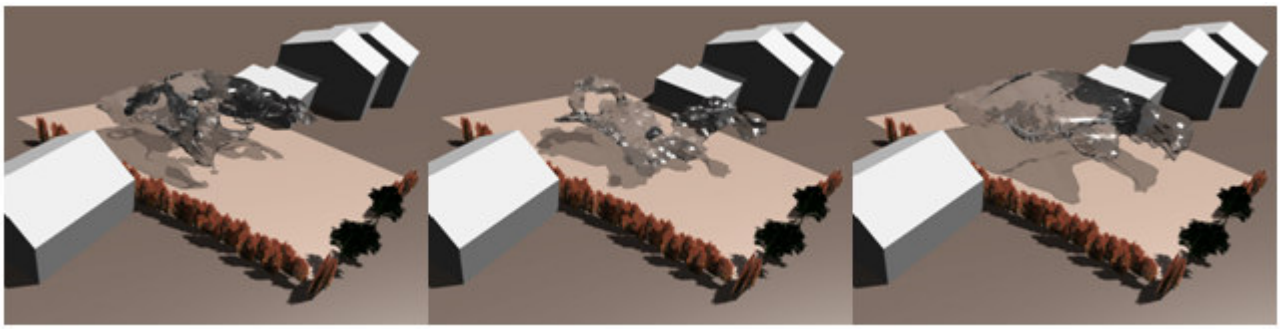
Quellen Nr. 1, 2 und 3 . Renderings © 2009 Wolfgang Höhl, München

„Säulen“:



Säulen Nr. 1, 2 und 3 . Renderings © 2009 Wolfgang Höhl, München

„Wolkenbügel“:



Wolkenbügel Nr. 1, 2 und 3 . Renderings © 2009 Wolfgang Höhl, München

6.8 Neuerliche Prüfung von Verschattung und Besonnung

In diesem Fall habe ich mich für den generativen Entwurf „Wolkenbügel Nr. 3“ entschieden. Sie hat ein Volumen von 479,95 m³. Selbstverständlich können weitere, alternative Parameter zur Auswahl der optimalen Form frei gewählt werden. Beispielsweise können sich räumlich zusammenhängende Formen besser eignen, als disperse. Danach kann die Optimierungsschleife wiederholt werden: Besonnung und Verschattung werden geprüft und der Baukörper neu gestaltet.

6.9 Remodeling von Schattenkörper und Baumasse

Das Remodeling ist in diesem Beitrag nicht explizit dargestellt. Es funktioniert durch einfachen Neustart des Prozesses und eine wiederholte Optimierungsschleife, bis die optimale Form gefunden ist.

6.10 Wiederholung der Optimierungsschleife bis zum finalen Rendering

7 CONCLUSION

Sehr zufrieden kann man mit dem Gesamtverhalten des Systems sein. Die Ergebnisse sind im Entwurfsprozeß sehr gut anwendbar. Der Datenaustausch zu anderer Standardsoftware funktionierte sehr gut.

Die Pythonscripts lieferten einwandfreie Ergebnisse. Abhängig vom verwendeten Betriebssystem und der verwendeten Blenderversion gab es geringe Unterschiede in der Performance.

Das Erstellen der Verschattungsbilder mittels Texture Baking funktionierte sehr gut, genauso wie die Montage der Einzelbilder mit GIMP und der Wiederimport der Grafiken als UV-Texturen. Dieses Offline-Verfahren ist hier zeitlich noch sehr umfangreich und kann bestimmt an vielen Stellen über geeignete Scripts automatisiert werden.

Die Wege zur automatisierten Formgenerierung der Schattenkörper können ausgebaut und verbessert werden. Momentan ist hier vorwiegend der Nutzer des Systems gefragt.

Die Werkzeuge zur Fluidsimulation verhielten sich stabil, die Anwendung ist relativ einfach. Etwas umständlich bleibt allerdings noch die Volumensbegrenzung mittels des Pythonscripts quantitybill.py. Zukünftig wird zu testen sein, ob nicht andere Werkzeuge wie zum Beispiel Partikelsysteme bessere, schnellere und genauere Ergebnisse liefern können. Gerade in Hinblick auf die Entwicklung von konstruktiv relevanten und statisch wirksamen Baukörperformen könnte das interessante Wege aufzeigen.

Sehr erfolgreich verliefen auch, hier nicht näher bezeichnete Versuche, die Verschattungsberechnung geschossbezogen, in kleineren Einheiten zu wiederholen und den Baukörper dementsperechend zu remodellieren.

Komplementär zu dieser Offline-Technologie bieten heute neue Echtzeit-Renderingverfahren (z.B. mit der kostenpflichtigen Software EcoTect) einfachere Möglichkeiten der interaktiven Sonnenstandssimulation. Diese Technologie verdeutlicht sofort und in Echtzeit das Schattenbild eines bestimmten Gebäudeentwurfs. Dies ist in zweierlei Hinsicht nützlich: einerseits während des Entwurfs für den gestaltenden Architekten, andererseits zur Bewertung fertiger Entwürfe durch die Wettbewerbsjury oder den Bauherrn.

(1) Verschattung Grundstück mit Nachbarbebauung, (2) maximal besonnte Grundfläche und (3) nach der Besonnung optimierter Architekturentwurf . Simulationen mit EcoTect . Computer Generated Images (CGI) . © 2010 Wolfgang Höhl, München

Diese Computersimulationen bilden in diesem Bereich ein wertvolles Werkzeug, mit dem unsere Häuser tatsächlich zu Akkumulatoren der Sonnenwärme werden können.

GeoFinanzen: Unterstützung kommunaler Entscheidungsprozesse durch kartographische Präsentation von Finanzdaten

Anja Matatko

(Dipl.-Geogr. Anja Matatko, Universität Trier, FB VI, Kartographie, 54286 Trier, matatko@uni-trier.de)

1 ABSTRACT

Städte sind geprägt durch Soziale Ungleichheit und das Fehlen finanzieller Mittel. Entscheidungen über die Zukunft der Städte werden von Gremien getroffen, die auf aus den Verwaltungen stammende Informationsquellen zurückgreifen müssen. Die Daten, die dabei zugrunde liegen, haben zwar räumlichen Charakter, werden jedoch meist in nicht-räumlichen Präsentationsformen dargeboten. Daraus resultiert ein Mangel an raumbezogenem Wissen, der mit der in der vorliegenden Arbeit diskutierten Vorgehensweise behoben werden soll. Als Anwendungsbeispiel dient dabei der Haushalt der Stadt Trier. GeoFinanzen verortet Daten aus dem Ergebnis- und Finanzhaushalt 2009, führt diese zusammen, verschneidet sie mit sozio-demographischen Merkmalen und ermöglicht dadurch neue Einblicke in räumliche Zusammenhänge im Sinne einer explorativen Datenanalyse (Spatial Data Mining). Neben der Haushaltsaufstellung können die aufbereiteten Daten auch als Controllinginstrument der Verwaltung genutzt werden. Fachplaner können mit adaptierten Versionen themenspezifische Erkenntnisse gewinnen und in zukünftige Planungen einarbeiten. Finanzen und Raum können somit zu einer Einheit werden, in der sozialräumliche Disparitäten auch unter Einsatz entsprechender finanzieller Verteilungsrelationen innerhalb der Städte bekämpft werden können. Die Zielgruppe bilden kommunale Entscheider, wobei neben der Politik auch Verwaltung sowie die Bürger in Frage kommen. Dabei ist darauf zu achten, dass die Zielgruppen in dem betrachtenen Handlungsprozess der Haushaltsaufstellung unterschiedliche Handlungen vollziehen und daher die kartographischen Medien entsprechend nutzerorientiert gestaltet werden müssen. Der vorliegende Beitrag stellt die Vorgehensweise zur Aufbereitung der Haushaltsdaten und Einsatzbereiche von GeoFinanzen vor.

2 EINFÜHRUNG

“Wohin fließt eigentlich das Geld in der Stadt?” war die Eingangsfragestellung, die die Autorin zur Bearbeitung des vorliegenden Themas veranlasste. Falls sich in der Verteilung der Finanzströme einer Kommune bestimmte räumliche Muster aufdecken lassen, könnte dieses Wissen in Zukunft genutzt werden, um eine einseitige Mittelverteilung zu vermeiden. Das Ziel liegt dabei nicht darin, eine homogene Mittelverteilung zu fordern – vielmehr möchte GeoFinanzen mit der Georeferenzierung von kommunalen Finanzdaten ein Bewusstsein für die Dimension „Raum“ in Zusammenhang mit Investitionen und Leistungszuweisungen schaffen. In diesem Artikel wird ein Einblick in das Forschungsprojekt gegeben und Zwischenergebnisse präsentiert.

Kapitel 2 stellt den Handlungsbedarf auf kommunaler Ebene hinsichtlich der Haushaltsauftsellung vor und ordnet somit die Aufgabenstellung von GeoFinanzen in den kommunalpolitischen und wissenschaftlichen Kontext ein. Neben der Vertiefung der relevanten Handlungszwänge werden die Möglichkeiten der Kartographie aufgezeigt, innerhalb der bei der Haushaltsaufstellung stattfindenden Entscheidungsprozesse Unterstützung zu leisten. Kapitel 3 stellt Methodik und Resultate der Georeferenzierung des Trierer Kommunalhaushaltes dar. Kapitel 4 beschäftigt sich abschließend mit Analysen, die mit den aufbereiteten Daten durchgeführt werden können und somit neue Einblicke in Stadtstrukturen liefern, sowie deren Umsetzung in sog. Kartographische Modellformen. Des Weiteren werden, mit Bezug auf die in Kapitel 2 dargestellten kommunalen Entscheidungsprozesse bei der Haushaltsaufstellung, Einsatzmöglichkeiten von GeoFinanzen aufgezeigt. Ein Ausblick auf die weiteren Entwicklungsschritte schließt die Arbeit ab.

3 KOMMUNALER HANDLUNGSBEDARF BEI DER HAUSHALTSAUFSTELLUNG

Der Handlungsbedarf bei der kommunalen Haushaltsaufstellung ist durch zwei große Einflussgrößen gegeben: die Zunahme der Partizipation der Bürgerinnen und Bürger und die damit verbundene Anforderung der transparenten Haushaltsaufstellung sowie die Frage der Sozialen Ungleichheit, deren Bekämpfung eines der Ziele kommunaler Stadtplanung darstellt. Neben Erläuterungen zu transparenter Haushaltsaufstellung und räumlichen Disparitäten werden in diesem Kapitel abschließend die Akteure, der Prozess der Haushaltsaufstellung und die daraus resultierenden möglichen Handlungsfelder der Kartographie gegenüber gestellt.

3.1 Transparenz der Haushaltsaufstellung

In den letzten Jahren, die von leeren öffentlichen Kassen gekennzeichnet waren, trat bei kommunalen Akteuren verstärkt die Auffassung ein, dass Bürger einer Stadt in die Haushaltsaufstellung eingebunden werden sollten. Nicht zuletzt, um Kürzungen und Streichungen besser kommunizieren zu können. Die Idee des Bügerhaushalts ist keineswegs neu, der erste wurde bereits im Jahr 1989 in Porto Alegre (Brasilien) aufgestellt. Die Umsetzung in den deutschen Kommunen erfolgte seitdem jedoch bei Weitem nicht flächendeckend. Über 200 Kommunen arbeiten in Europa, Amerika und Australien bereits mit diesem neuen Beteiligungsinstrument (BAUMANN U. A. 2003). Bürgerhaushalte können in unterschiedlichen Verfahren aufgestellt werden. Gemeinsam ist diesen die Konzentration auf eine Information und Mitsprache (in unterschiedlichem Ausmaß) der Bürger. Der Aufstellungsprozess eines Bürgerhaushalts ist formal gesehen identisch mit dem eines ohne Beteiligungsverfahren erstellten Kommunalhaushalts (dargestellt in Abb. 1). Er unterscheidet sich nur hinsichtlich der Akteure, die zwischen den Schritten „Einbringung Etatentwurf“ und „Verabschiedung Etat“ einbezogen werden: zu den Kommunalpolitikerinnen, Kommunalpolitikern, Verwaltungsmitarbeiterinnen und Verwaltungsmitarbeitern gesellen sich die Bürgerinnen und Bürger. Problematisch bei Bürgerhaushalten stellt sich die Komplexität der Haushaltsmaterie dar. Ein Konzept zur transparenten Aufbereitung des Haushalts zur Weiterentwicklung des Bürgerhaushalts wird daher von BAUMANN U. A. (2003) gefordert. Die Autoren sind der Meinung, dass eine stadtteilbezogene Darstellung des Haushalts die Bürger vor Ort besser erreichen könne. Marzahn-Hellersdorf hat eine solche sozialräumliche Haushaltsdarstellung vorgenommen. Die räumliche Auflösung (Stadtteil) ist jedoch sehr ungenau. Zudem wurden jeweils nur ausgewählte Aufgaben von den Fachabteilungen bewertet und räumlich aufgegliedert. Auch in anderen Kommunen, national wie international (z.B. St. Denis in Frankreich), wird eine Aufsplittung der Investitionen nach Stadtteilen vorgenommen. Der Bürgerhaushalt Berlin-Lichtenberg berücksichtigt die räumliche Dimension der Maßnahmen insofern, dass bei den Beschreibungen der einzelnen Leistungen des Bezirksamtes eine Aufschlüsselung nach den räumlichen Untereinheiten, den Stadtteilen, erfolgt (BEZIRKSAMT LICHTENBERG VON BERLIN 2007). Für die gruppierten Leistungen wird angegeben, welcher Anteil jeweils auf einen Stadtteil entfällt. Dabei werden verschiedene Indikatoren zur Berechnung der Anteile verwendet, z.B. Anzahl der Einwohner je Stadtteil bei der Sportförderung. Wirkungsradien der Maßnahmen bzw. die Ausgaben des Verwaltungshaushalts spielen dabei jedoch keine Rolle, ebenso wenig die Gegenüberstellung der Stadtteile zu einem gesamtstädtischen Wirkungsgefüge oder eine kleinräumige kartographische Darstellung. In der Stadt Trier wurde für das Haushaltsjahr 2010 erstmals ein Bürgerhaushalt aufgestellt (VORWERK/LOOSEN-BACH 2009).

3.2 Soziale Ungleichheit und Räumliche Disparitäten

HRADIL (2001, S. 28f.) nennt drei Komponenten Sozialer Ungleichheit: zum Einen betrifft sie durch Werte der Gesellschaft geprägte Güter, die als wertvoll gelten, zum Anderen deren ungleiche Verteilung in der Gesellschaft, die zudem regelmäßig erfolgt. Mit dem Zusammenhang zwischen Sozialer Ungleichheit und der räumlichen Dimension beschäftigen sich besonders die Sozialgeographie, die Stadtgeographie und die Stadtsoziologie. Die räumliche Problematik der Sozialen Ungleichheit besteht darin, dass benachteiligte Bevölkerungsgruppen über geringe Ressourcen verfügen und somit auf günstigen Wohnraum angewiesen sind. Sie sammeln sich daher in bestimmten Stadtquartieren, wodurch Prozesse des down-cycling und der Segregation eingeleitet werden. Letztere hat zwar nicht nur Nachteile, wie z.B. von… HÄUßERMANN (2005) untersucht. FRIEDRICH (1999, S. 282) geht davon aus, dass sich selbst verstärkenden Effekte der Dimensionen räumlicher Armut in Zukunft immer stärker angreifen und in ghettoähnlichen Vierteln münden, in denen sich soziale Ausgrenzung räumlich verfestigt. Als Lösung des Dilemmas fordert sie eine Eingrenzung marktwirtschaftlicher Prinzipien in der Stadtpolitik. Negativ wirkt Segregation dadurch, dass schlechte Ausstattung, periphere Lage und negatives Image des Wohnumfelds die soziale Ausgrenzung der von Armut betroffenen Menschen verstärken (vgl. SCHACHT (1999, S. 290)). In der Stadtsoziologie gibt es eine Diskussion über den Raumbezug Sozialer Ungleichheit, die sich zwischen der Idee der Enträumlichung und der Verräumlichung bewegt. DANGSCHAT/HAMEDINGER (2007, S. 12) schließen sich der zweiten Gruppe an und betonen, dass der “physische Raum (...) zugleich Ressource und Constraint für das Handeln des Individuums, das sich mit anderen in Konkurrenz um die Besetzung und Verteidigung des Territoriums befindet“, sei.

Der Zusammenhang zwischen Sozialer Ungleichheit und Raum wird von einigen Stadtgeographen in Frage gestellt. So sieht BECK (1986, 137f.) im Rahmen der Lebensstildiskussion „neue, typischerweise sozial gemischte urbane Stadtsiedlungen“ anstelle der zuvor existierenden proletarischen Milieus. Ebenso schreibt Schulze (1992) von einem Rückgang der Segregation und der geographischen Signifikanz von Herkunft und Wohnumfeld. Seine Aussage, „Für unsere Alltagswahrnehmung gilt immer mehr jeder kann überall wohnen; seine gegenwärtige und vergangene Umgebung informiert nur wenig über Existenzformen“ (SCHULZE (1992, 196)) trifft auf die Struktur der Stadt Trier jedoch in keinster Weise zu. Drei Gebiete der Stadt sind bereits als Programmgebiete der Sozialen Stadt deklariert, weitere Gebiete befinden sich in einem deutlichen Abwärtstrend. Nach ROSOL (2009) ist das Eintreten der Stadtplanung für Unterprivilegierte im Sinne einer parteilichen Anwaltsplanung bedingt durch den neoliberalten Umbau der Städte in den Hintergrund gerückt. Dennoch stellt sich Kommunen nach wie vor die Frage, wie die negativen Folgen der Ungleichheit zum Wohle der gesamten Stadt abgemildert werden können.

Zur Messung von Sozialer Ungleichheit bestehen Indikatoren-Sets, wie von FALLER U. A. (2005) für die Stadt Saarbrücken entwickelt. Diese Indikatoren umfassen die Themnbv men Einkommen, Wirtschaft, Bildung/Qualifizierung, Bevölkerungs- und Haushaltsstruktur sowie Wohnen. Mit Hilfe der Indikatoren können Teilräume einer Stadt in ihrer Heterogenität dargestellt werden. Keiner der Indikatoren berücksichtigt jedoch, dass auch die Kommune selbst durch ihr Handeln Ungleichheit befördern oder abbauen kann. Durch die Georeferenzierung von Finanzdaten kann überprüft werden, ob insbesondere im investiven Bereich durch Ungleichbehandlung von Stadtquartieren Negativimages befördert und so die Abwärtsspirale weiter in Gang gesetzt wird.

3.3 Entscheidungsprozesse bei der Haushaltsaufstellung und Übertragbarkeit auf kartographische Handlungsfelder

An den Entscheidungen, die im Rahmen einer Haushaltsaufstellung getroffen warden müssen, sind viele Akteure beteiligt. Diese unterscheiden sich hinsichtlich ihres Vorwissens und ihrer Fähigkeiten. Abbildung 1 stellt den Ablauf der Haushaltsaufstellung in Zusammenhang mit den drei Akteursgruppen Verwaltung, Bürgerinnen, Bürger und Stadtrat dar. Der Etat wird zunächst durch den (Ober)Bürgermeister in den Stadtrat eingebracht. Dieser Entwurf wird dann anschließend im Rahmen der Bürgerbeteiligung diskutiert. Die Fraktionen beraten über die Ergebnisse, zunächst intern, anschließend im zuständigen Ausschuss. Den Abschluss stellen der öffentliche Beschluss sowie die Veröffentlichung des Etats dar. An allen Stellen im Entscheidungsprozess findet Kommunikation statt und werden Informationen ausgetauscht, wobei der Grad der Beteiligung der Akteure variiert. Im Rahmen des Bürgerhaushalts kann zudem der Zeitpunkt der Beteiligung der Bürger variieren. Zwei grundlegend unterschiedliche Ansätze bestehen in der Beteiligung der Büger/-innen entweder vor der Einbringung des Etatentwurfs (allgemeine Diskussion haushaltsrelevanter Fragestellungen) oder nach der Einbringung des Etatentwurfs (konkrete Diskussion der im Haushaltsplan stehenden Maßnahmen). Die räumliche Dimension der Entscheidungen in politischen Gremien wird von deren Mitgliedern zwar erkannt, so DAPP (2005), allerdings erfolgt keine entsprechende technische Unterstützung der Abgeordneten in Form von interaktiv einzusetzenden GIS, weshalb der Raumbezug in Diskussionen des Landtags sehr allgemein bleibe oder sich konkret auf die jeweiligen Heimatwahlkreise der Abgeordneten beziehe, für die diese ein stark ausgeprägtes Detailinteresse haben.

Den erforderlichen Kommunikationsprozessen können aus kartographischer Sicht zwei Handlungsfelder (nach BOLLMANN 1993) zugeordnet werden: Kartographische Informationsverarbeitung und raumbezogene Unterrichtung und Mitteilung. Kartographische Handlungsfelder stellen einen modelltheoretischen Ansatz der Kartennutzung dar, in dem der organisatorisch-kommunikative Zusammenhang zwischen georäumlichen Handlungen und den Formen der Unterstützung durch kartographische Medien abgebildet wird. Die Abgrenzung der insgesamt acht verschiedenen Handlungsfelder erfolgt auf der Grundlage des jeweils erforderlichen Informationsbedarfs und -austausches. Das Ziel der kartographischen Handlunsgfelder ist eine optimale Aurichtung der kartographischen Medien auf die jeweiligen Handlungsabläufe. Abbildung 1 stellt den Prozess der Haushaltsaufstellung, die daran beteiligten Akteure sowie daraus resultierende betroffene kartographische Handlungsfelder dar.

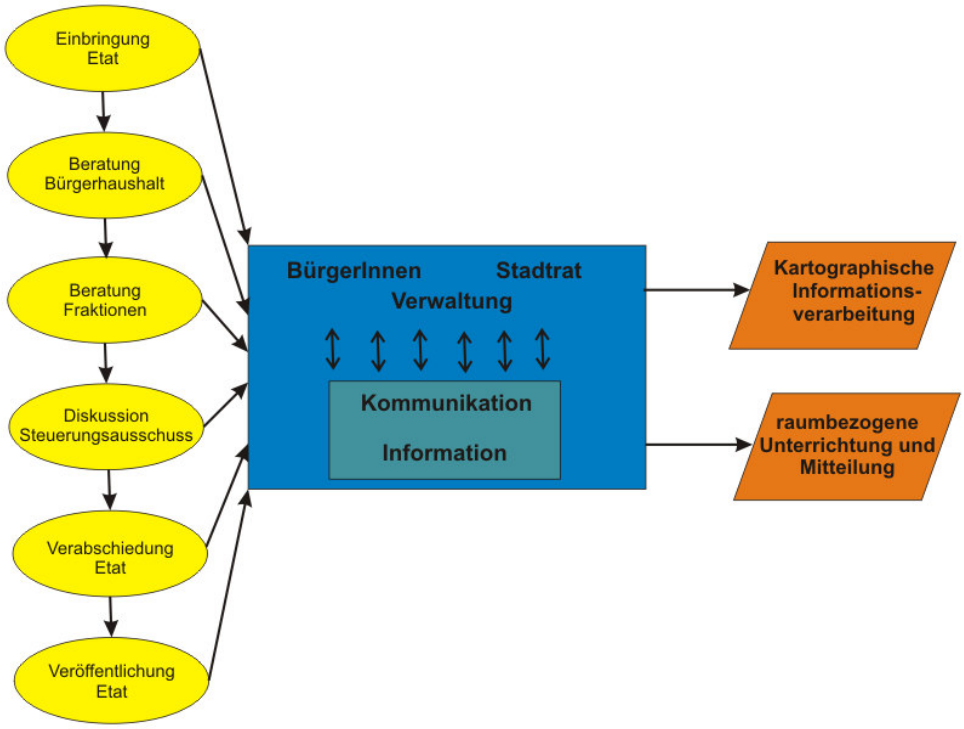

Abb. 1: Ablauf der Haushaltsaufstellung, Akteure und kartographische Handlungsfelder

3.3.1 Handlungsfeld Kartographische Informationsverarbeitung

Geographische Informationssysteme und andere Visualisierungswerkzeuge ermöglichen das Durchführen von numerischen, geometrischen und logischen Operationen sowie kognitive Analyse- und Bewertungsvorgänge. Nach BOLLMANN/UTHE (2002) werden unter diesem Handlungsfeld die GIS-Funktionsbereiche Visualisierung und Datenexploration subsumiert. Als wesentliches Kennzeichen des Handlungsfeldes halten die Autoren die wiederholte gedankliche Transformation von Daten in Informationen oder Wissen fest. Die inhaltlichen Schritte der kognitiven Verarbeitung der dargestellten Informationen bestehen beispielsweise in der Auswertung von Nachbarschaftsbeziehungen, Verteilung von Minimal- und Maximalwerten oder Clusteridentifikation. Dies geschieht besonders durch interaktive Präsentation der Daten, die wiederum eine schnelle Transformation der Inhalte ermöglicht.

3.3.2 Handlungsfeld Raumbezogene Unterrichtung und Mitteilung

Nach BOLLMANN/UTHE (2002) ist die raumbezogene Unterrichtung insbesondere in Verwaltungen oder größeren Unternehmen relevant. Der Einsatz von kartographischen Medien in diesem Handlungsfeld ist stark standardisiert, dargestellt werden Ergebnisse eines Bearbeitungsvorgangs oder mögliche Ausführungsvarianten. Raumbezogene Mitteilung versammelt sämtliche Handlungen, bei denen die Vermittlung georäumlicher Informationen zur Meinungsbildung oder Verhaltensauslösung führen soll. Bei den Darstellungen handelt es sich entweder um allgemeine, langfristig gültige Beschreibungen georäumlicher Situationen oder zeitlich begrenzte Sachverhalte. Insbesondere im Bereich der Massenkommunikation wird mit dieser Handlungsform gearbeitet. Entsprechend steht die Verständlichkeit der Informationen im Vordergrund, die Darstellungsform hingegen ist nicht oder wenig standardisiert. In GeoFinanzen kommen beide Teilbereiche des Handlungsfelds zum Tragen: Raumbezogene Unterrichtung, insofern interne Abstimmungsprozesse der Verwaltung betroffen sind, und Raumbezogene Mitteilung, insofern es um Kommunikation zwischen den unterschiedlichen Akteursgruppen geht.

4 GEOREFERENZIERUNG: VORGEHENSWEISE UND ERGEBNISSE

Ziel von GeoFinanzen ist unter anderem, darzustellen, wie Haushaltsdaten räumlich aufbereitet werden können. Die tatsächliche Georeferenzierungsquote einer Kommune ist dabei stark von der bisherigen Datenhaltung abhängig. Im Anwendungsbeispiel, der Stadt Trier, erfolgt die Datenhaltung stark dezentral. Somit unterscheiden sich die Voraussetzungen für eine erfolgreiche Georeferenzierung sehr stark nach den einzelnen Ämtern. In diesem Kapitel sollen grundsätzliche Überlegungen zur Datenaufbereitung sowie

einige Ergebnisse aus Ämtern präsentiert werden, die als stellvertretend für die drei Hauptgruppen der Datenverfügbarkeit betrachtet werden können.

4.1 Datenaufbereitung

Als Ansatz zur Georeferenzierung stehen zwei verschiedene Sichtweisen des Raumbezugs zur Verfügung. Zum Einen kann der konkrete Ort einer Investition berücksichtigt werden. Zum Anderen können jedoch auch diejenigen, die von der Investition profitieren, betrachtet werden. Zudem ist im Haushalt zu differenzieren zwischen Einzel- und Sammelpositionen. Einzelpositionen betreffen konkrete Objekte, Sammelpositionen werden nach Bedarf verausgabt. Daher kann bei Sammelpositionen vorab kein Raumbezug hergestellt werden. Es ist jedoch möglich, die Sammelpositionen ex post zu betrachten, und das räumliche Ergebnis des Vorjahres, soweit keine inhaltlichen Gründe dagegen sprechen, auf das Folgejahr fortzuschreiben.

Die unterschiedlichen Leistungen einer Kommune können differenziert werden in nicht räumliche, indirekt räumliche und direkt räumliche Leistungen. Nicht räumlich sind dabei Positionen wie Zinsen oder Verwaltungsinterna (z.B. Rechtsamt, Protokollreferat). Diese werden nicht in den georeferenzierten Haushalt einbezogen. Zinsen und Abschreibungen sind ggf. enthalten, wenn sie den einzelnen Produkten, die georeferenzierbar sind, haushaltärisch zugeordnet sind. Direkt räumlich sind Plandaten für das Folgejahr, die konkrete Investitionen betreffen, wie z.B. in Gebäude und Straßen. Reaktive Maßnahmen werden im Haushalt in Sammelpositionen abgebildet, weshalb, wie oben beschrieben, eine Betrachtung in diesem Falle nur rückwirkend möglich ist. Die dritte Gruppe bilden die indirekt räumlichen Maßnahmen, d.h., Institutionen oder Personen, die Leistungsempfänger sind. In diesen Fällen erfolgt keine sichtbare Investition der Finanzmittel, aber die Begünstigten leben an einem bestimmten Ort und sind somit prinzipiell georeferenzierbar. Abbildung 2 stellt die Varianten des Raumbezugs in Kombination mit dem jeweils verwendeten Zeithorizont anhand von Beispielen gegenüber.

Abb. 2: Raumbezug im kommunalen Haushalt

4.2 Raumbezugseinheiten

Bei der Georeferenzierung der Aufgaben des Kommunalhaushalts stellt sich die Frage, welche Raumbezugseinheit zur Verortung der Daten genutzt werden soll. Einige Datenquellen konnten adressbezogene Daten zur Verfügung stellen. GeoFinanzen hat jedoch die Belange des Datenschutzes zu berücksichtigen, weshalb eine adressgenaue Präsentation der Daten nicht möglich ist. Somit kommen die administrativen Einheiten der Stadt Trier in Frage: 99 Statistische Bezirke und 19 Stadtbezirke. Bei den durchzuführenden Analysen und der Interpretation insbesondere statistischer Kennzahlen sind die Probleme der Auswirkung unterschiedlicher Raumbezugseinheiten, das sog. Modifiable Area Unit Problem (siehe hierzu WONG/LEE (2005) und FOTHERINGHAM ET AL. (2000)), zu berücksichtigen.

4.3 Ergebnisse

Das Ergebnis der Georeferenzierung soll beispielhaft demonstriert werden anhand der Daten aus den Ämtern Theater, Gebäudewirtschaft und Soziales. Dabei werden die unterschiedlichen Varianten der Georeferenzierung vorgestellt (direkter und indirekter Raumbezug).

4.3.1 Theater

Nutzer und Nutzerinnen der Infrastruktur städtisches Theater gehören nach der in Abb. 2 dargestellten Gliederung zu den indirekt räumlichen Maßnahmen. Nicht der Stadtteil, in dem die Aufführungen stattfinden, profitiert davon, sondern der Personenkreis, der die Aufführungen besucht. Insofern ist für eine Georeferenzierung der Theaterausgaben die Erfassung der Anschrift der Kunden bei den einzelnen Verkaufsvorgängen erforderlich. Dies erfolgt derzeit am Theater Trier nicht, weshalb eine Georeferenzierung an diese Stelle zwar prinzipiell möglich, aber aus technischen Gründen nicht leistbar ist. Wenn eine Kommune ihre Ausgaben vollständig georeferenzieren möchte, wäre dies jedoch durch entsprechende Aufrüstung des Kassensystems möglich. Identische Probleme treten z.B. bei Museen auf.

4.3.2 Gebäudewirtschaft

Das Amt für Gebäudewirtschaft beschäftigt sich mit der Instandhaltung und Sanierung des kommunalen Gebäudebestandes. Dabei werden Maßnahmen durchgeführt, die schon im Vorjahr geplant und entsprechend in den Haushalt geschrieben werden. Diese können georeferenziert werden, wobei der Standort einfach, der Wirkungsradius jedoch ggf. über Expertengespräche, bei Schulen ggf. über eine Georeferenzierung der Herkunft der Schülerinnen und Schülern, zu bestimmen ist. Die Gebäudewirtschaft verfügt auch über mittelfristige Planungsdaten hinsichtlich des Investitionsbedarfs in kommunalen Gebäuden.

Zudem existieren etliche Maßnahmen, die nach Bedarf durchgeführt werden, insbesondere im sicherheitstechnischen Bereich. Diese Maßnahmen sind noch nicht objektbezogen im Haushalt enthalten, sondern unter Sammelpositionen, z.B. „Sicherheitstechnische Maßnahmen an Grundschulen“, subsumiert. Zur Georeferenzierung bieten sich somit nicht die Daten im aktuellen Haushalt an, sondern ausschließlich eine ex-post-Betrachtung der Vorjahresergebnisse. Doch auch bei jenen hält die Stadtverwaltung Trier die Ausgaben derzeit nicht komplett objektbezogen vor. Daher handelt es sich auch bei den reaktiven Maßnahmen um Ausgaben, die zwar prinzipiell verortet werden könnten, aber zunächst müssten die technischen Erfassungsmöglichkeiten entsprechend genutzt werden.

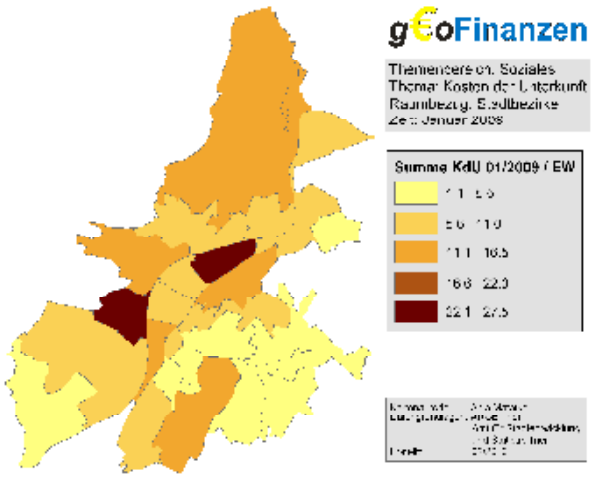

Abb. 3: Georeferenzierungs-Ergebnis KdU/EW (links) und Leser der Stadtbibliothek (rechts)

4.3.3 Sozialbereich

Im Sozialbereich werden keine Investitionen getätigt, sondern Zuschüsse an Maßnahmeträger oder Leistungen an Leistungsbezieher gezahlt. In diesem Bereich ist der Datenschutz besonders relevant. Ausgaben, die sich direkt an die Leistungsbezieher richten, stellen keine Investition in die Wohnumfeldqualität dar und sind somit bei einem Stadtteilvergleich nicht relevant, da die Höhe der Zahlungen eine Wirkung, keine Ursache benachteiligter Stadtteile ist. Die Verteilung der Leistungsempfänger im Bereich Kosten der Unterkunft (KdU), dargestellt in Abb. 3 (links), entspricht dem Bild der Sozialstruktur der Stadt Trier. Die größten Anteile befinden sich in den drei Stadtteilen, die bereits

als Soziale-Stadt-Programmgebiete aufgenommen wurden. Ein weiteres Georeferenzierungs-Ergebnis aus dem Kultursektor, die Kunden der Statdtbibliothek, dargestellt in Abb. 3 (rechts), zeigt ein komplett anderes räumliches Muster. Bezogen auf die Einwohner insgesamt ergibt sich eine sehr heterogene Verteilung der Leserschaft im Stadtgebiet.

5 DATENANALYSEN UND KARTOGRAPHISCHE PRÄSENTATION

Mit den georeferenzierten Daten ist es möglich, einzelne Themen oder Kombinationen von Themen kartographisch darzustellen und auf verschiedene Bezugsgrößen zu beziehen. In diesem Kapitel werden theoretisch mögliche Analysen und für die Visualisierung jeweils geeignete kartographische Modellformen vorgestellt. In der im Ausblick erläuterten empirischen Untersuchung zur Wirksamkeit der kartographischen Präsentationen zur Entscheidungsunterstützung werden diese sowie der Freiheitsgrad der Interaktion als unabhängige Variablen genutzt.

5.1 Analysen

Methodisch gesehen kommen zwei Gruppen von Analysemethoden in Betracht. In dieser Arbeit werden neben strukturentdeckenden Verfahren des Spatial Data Minings strukturprüfende Verfahren eingesetzt. Beide können, je nach Fragestellung, die mit Hilfe der Geodaten beantwortet werden soll, neue Informationen über räumliche Zusammenhänge liefern.

Bei den strukturprüfenden Verfahren ist insbesondere die Regressionsanalyse von Bedeutung. Sie ermöglicht die statistische Auswertung signifikanter Zusammenhänge. Insbesondere eine räumliche Auswertung der Residuen einer Regressionsanalyse kann in Bezug auf räumliche Disparitäten aufschlussreich sein. Um zu überprüfen, ob es in einer Kommune Korrelationen zwischen den herkömmlichen Indikatoren sozialer Ungleichheit (s. Kap. 2.2) und der Verteilung von Finanzmitteln gibt, werden nicht alle georeferenzierbaren Finanzdaten benötigt. Sinnvoll ist an dieser Stelle nur die Verwendung der Daten, die zu einer Verbesserung der Stadtteilstruktur führen. Eine Einbeziehung der Daten, die keine Auswirkung auf das Wohnumfeld haben, wie die Leistungen der Sozial- und Jugendhilfe, würde aufgrund der hohen Korrelationen zwischen den Indikatoren Sozialer Ungleicheit und der Verteilung der Leistungsempfänger keine stringenten Ergebnisse liefern. Der Inhalt der Regressionsanalyse kann als mehrschichtige Karte dargestellt werden. Für die Residuen der Regressionsanalyse bietet sich eine Visualisierung als Choroplethenkarte an.

Spatial Data Mining stellt eine Erweiterung des allgemeineren Begriffs Data Mining um die räumliche Dimension dar. Data Mining wird in unterschiedlichen Zusammenhängen definiert. Bei MITRA/ACHARYA (2003) und MILLER/HAN (2001) finden sich Diskussionen der diversen Sichtweisen. In dieser Arbeit wird eine aus UMSTÄTTER (2005) und MAY (2004) abgeleitete Definition zugrunde gelegt. Demnach geht es darum, in umfangreichen, digital vorliegenden Datenbeständen, interessante, versteckte Muster mit Hilfe von zum Teil automatisierbaren Suchwerkzeugen durchzuführen. Mit Hilfe von Spatial Data Mining können neue Informationen zur Entscheidungsunterstützung bei räumlichen Fragestellungen generiert werden, ohne dass zuvor Hypothesen aufgestellt werden müssen. Als Analyseverfahren stehen z.B. Clusteranalysen und Klassifizierungsregeln zur Verfügung.

Merkmal	Zeithorizont	Raumbezugseinheit	Inhaltliche Bezugsgrößen	Aggregatfunktionen
Varianten	Plandaten 2009 Ist-Daten 2008	Standort Statistischer Bezirk Stadtbezirk Gesamtstadt	Einwohner Kinder Senioren Fläche Haushalte	Ohne Summe Mittelwert

Tab. 1: Varianten von Karteninhalten

5.2 Visualisierung: kartographische Modellformen

Die darzustellenden Karteninhalte können differenziert werden nach inhaltlichen Bezugsgrößen, Raumbezugseinheiten, Zeithorizont und Aggregatfunktionen. Die einzelnen Differenzierungsmerkmale und deren Ausprägungsvarianten stellt Tab.1 zusammen.

Zur Visualisierung der Ergebnisse werden verschiedene kartographische Modellformen (zum Begriff der Modellform siehe BOLLMANN (2010)), von anderen Autoren auch als Kartentypen bezeichnet, eingesetzt. Nachfolgend werden die wichtigsten, für GeoFinanzen relevanten Modellformen erläutert. Weitere Gliederungsformen kartographischer Darstellungen finden sich bei BBSR (2009).

5.2.1 Modellform Choroplethen

Choroplethendarstellungen werden gewählt, um Wertrelationen darzustellen. Als Bezugsgröße können dabei z.B. Fläche, Einwohner gesamt, Kinder, Senioren genutzt werden. Mit Hilfe der Choroplethendarstellung können Cluster sehr schnell visuell erfasst werden. Dies ist auch bei der Generierung sog. Hot-Spots mit Hilfe statistischer Berechnungsverfahren eine deutliche Hilfe bei der Interpretation der Ergebnisse. Abb. 3 nutzt die Choroplethenkarte zur Darstellung der Verteilung von Leistungsempfängern und Lesern.

5.2.2 Modellform Flächendiagramm

Bei der Modellform Flächendiagramm werden Diagramme in Flächen platziert. Diese Darstellungsform eignet sich insbesonders, wenn Absolutwerte als Datengrundlage genutzt werden. Mit Hilfe der Diagramme können zudem Daten mehrerer Jahre gegenüber gestellt und somit Veränderungen im Zeitablauf visualisiert werden. Die Dimensionen Raum und Zeit können somit gemeinsam in Entscheidungsprozesse einfließen.

5.2.3 Modellform Standortdiagramm

Bei der Modellform Standortdiagramm werden Diagramme nicht in Flächen platziert, sondern jeweils Punktobjekten zugeordnet. Diese Modellform ist in GeoFinanzen vorgesehen für die Informationsvermittlung von standortbezogenen Daten, die nicht aufgrund von Datenschutzbelangen aggregiert werden müssen. Hierzu gehören z.B. Daten aus dem Bereich des Bauens. Abb. 4 zeigt das Georeferenzierungs-Ergebnis der kommunalen Gebäudewirtschaft. Dargestellt sind die für 2009 geplanten Investitionen. Deutlich wird dabei die Konzentration der Maßnahmen im Innenstadtbereich, was v.a. auf die Häufung von Schulen in diesem Bereich zurück zu führen ist. Bei der Betrachtung von Investitionen und der Bewertung von deren räumlicher Verteilung muss darauf geachtet werden, dass sich, je nach Jahr der Investition, das räumliche Bild schnell ändern kann. Um strukturelle Defizite aufzuzeigen, wäre somit eine längerfristige Betrachtung, z.B. von Dekaden, sinnvoll. Aufgrund der Umstellung des Rechnungswesens von kameralem auf doppischen Haushalt ist für die Stadt Trier eine solche Dekadenbetrachtung jedoch derzeit nicht durchführbar.

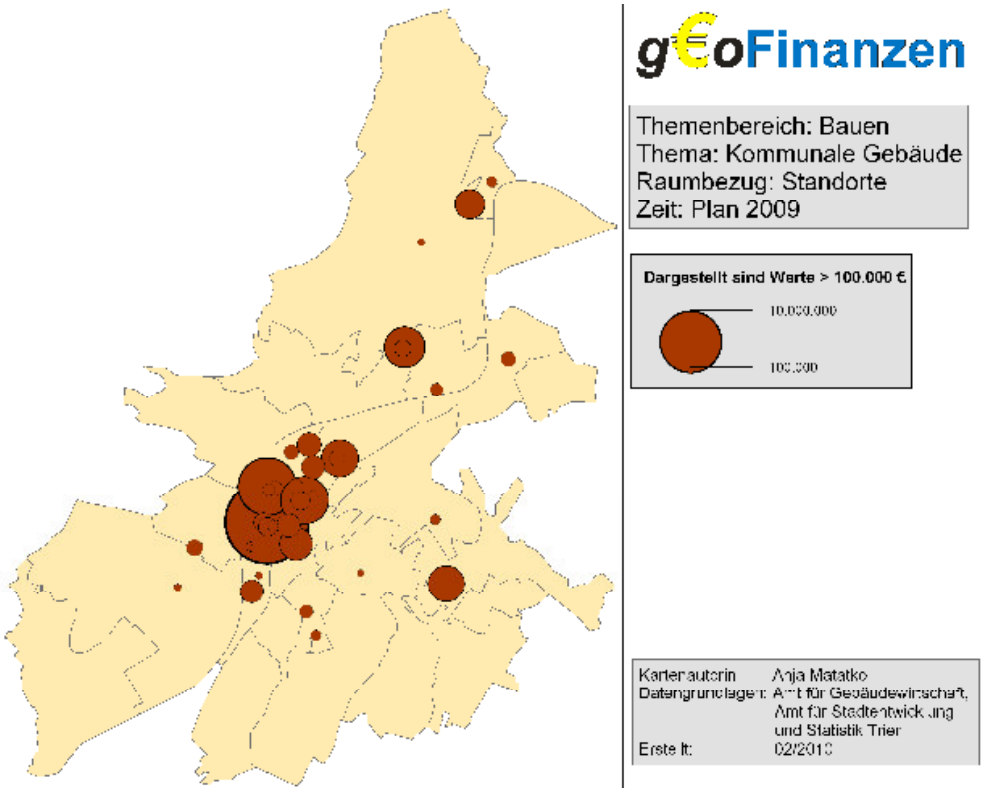

Abb. 4: Georeferenzierungs-Ergebnis Kommunale Gebäude Plan 2009

5.3 Einsatzbereiche von GeoFinanzen

Entsprechend der in Kapitel 2.3 vorgestellten kartographischen Handlungstheorie ergeben sich, unter Berücksichtigung der Ausführungen in Kapitel 3 und 4, zwei wesentliche Einsatzbereiche, in denen GeoFinanzen für Entscheidungsunterstützung sorgen kann.

5.3.1 Controlling

Verwaltungsintern sowie für die politischen Vertreter/-innen der Kommune kann GeoFinanzen im laufenden Haushaltsjahr als Controlling-Instrument genutzt werden. Technisch gesehen ist eine Anbindung der Finanzsoftware (SAP) an ein Georeferenzierungs-Tool mit interaktiver Kartenausgabe möglich. An Stelle des bisherigen Controllings, bei dem Plan- mit Ist-Werten verglichen werden, könnten so zudem die räumlichen Verteilungen der Ausgaben mit dem räumlichen Plan abgeglichen werden. Dann die Realisierungsquote eines kommunalen Haushalts liegt bei maximal 60%, weshalb selbst bei einer Planung, die keine Ungleichbehandlung vorsieht, aufgrund der Nicht-Realisierung zahlreicher Maßnahmen eine Schieflage bei der Verausgabung der Haushaltsmittel stattfinden kann.

5.3.2 Bürger-/Ratsinformation und Diskussionsplattform

Im Rahmen der Beteiligung von Bürger/-innen und Ratsmitgliedern müssen Informationen kommuniziert werden. GeoFinanzen bietet sich als räumliches Medium an, in dem komplexe Informationen visuell schnell erfasst werden können. Eine Steigerung zur reinen Mitteilung von Informationen stellt der Einsatz im Sinne einer Diskussionsplattform dar. Wie jede interaktive Kartenanwendung, könnten auch bei GeoFinanzen im Rahmen von web 2.0-Applikationen Funktionen der Rückmeldung und des Diskussionsaustausches vorgesehen werden. Es bietet sich an, neben der Darstellung der Haushaltsplanung dem Nutzer des Systems auch die Möglichkeit zu geben, Planwerte zu simulieren, um dadurch räumliche Veränderungen sichtbar machen zu können. Auch Bezugsgrößen (inhaltlicher und räumlicher Art) können ausgetauscht und dadurch neues Wissen generiert werden.

6 AUSBLICK

Bisher konnte im Rahmen des Forschungsvorhabens GeoFinanzen gezeigt werden, dass es prinzipiell möglich ist, Haushaltsdaten zu georeferenzieren und somit kartographisch aufbereiten zu können. Der Aufwand, der hierfür erforderlich ist, wird stark durch die bereits existierende Form der Datenerfassung innerhalb der Kommunalverwaltung bestimmt. Auch die Detailtiefe der einzelnen Leistungen im doppischen Haushalt stellt ein wichtiges Kriterium für die Georeferenzierbarkeit dar, da Sammelpositionen nicht oder nur mit Einschränkungen räumlich zugeordnet werden können.

Ziel von GeoFinanzen ist nicht, räumliche Disparitäten zu verhindern, sondern die Daten so aufzubereiten und zu präsentieren, dass die in die Entscheidungsprozesse involvierten Akteursgruppen in der Lage sind, entsprechend ihrer eigenen Meinung zur Frage des Für und Wider der Räumlichen Disparitäten Entscheidungen zu treffen. Daher wird in einem nächsten Schritt im Rahmen einer empirischen Untersuchung (im Sommer 2010) anhand der in diesem Beitrag dargestellten kartographischen Handlungsfelder untersucht, welche der möglichen Analysen und Präsentationsformen für welche Akteursgruppe an welcher Stelle im Entscheidungsprozess am besten geeignet sind, d.h., durch welche Unterstützungsform die räumlichen Informationen, die in einem Kommunalhaushalt enthalten sind, optimal an die kognitiven Prozesse der Informationsentnahme und –verarbeitung angepasst werden können. Bereits durchgeführte Expertengespräche mit Akteuren aus Politik und Verwaltung zeigen, dass das Interesse an einer transparenten, raumbezogenen Haushaltsdarstellung sehr groß ist.

Googlization Factors of Saudi Eastern Province Virtual Cities. Factors Analysis of Eastern Province Virtual Cities

Talal A Al-Hairig, Ahmed J Al-Jaralah

(Engineer Talal Al-Harigi, Saudi Aramco, P.O Box 6816, Dhahran 31311, Saudi Arabia talal@araburban.net)
(Prof. Ahmed J Al-Jaralah, Dammam University, Department of Urban and Regional Planning, Saudi Arabia, pro_ajj@hotmail.com)

1 ABSTRACT

Over the past urban areas evolves based on the human needs and the way they conduct their life activities. The agriculture era evolved the human settlements around the water and fertile lands. Then croup production and market start taking place within the settlement and re-shape its land uses.

The industrial revolution and car invention introduced industrial areas that evolved the transportation means and expanded the settlements size and changed its pattern. The human settlements become cities that have land use regulations, market mechanism, and civil infrastructure, political and environmental places.

These factors influenced the physical pattern of cities since then. On the last 20 years third evolution on emerged through Information Technology (IT) and starts showing their impact on means of human activities and consequently their settlements pattern. Various human activities used to be conducted by physical presence become attainable through virtual means. Consequently, urban areas have been influenced by the presence of IT and the policies governing it's penetration on the urban and regional level. This study attempts to study the phenomena of virtual cities in the Eastern Province in Saudi Arabia by relating their population size to their presence on the cyberspace.

Key words: Virtual cities, cyberspace, Saudi cities, Urban Information Technology, Eastern Province

2 SIGNIFICANCE OF THE STUDY

This study intended to provide new methods of analyzing cities virtual transformation through tracing its presence in the cyberspace. Furthermore, the study attempt to fill in a gap in the practical implementation on the Urban Planning practice in developing new tools relate the actual cities physical variation to their virtual cyber variation.

3 STUDY DESIGN AND METHODOLOGY

This part of the study dedicated to the study methodology which will lead to understanding the diffusion of Eastern Province cities in the cyberspace in relation to the cities size.

3.1 Study Methodology

The study used descriptive survey methodology and factor analysis as the goal of the study focus on exploring the phenomena of varies cities presence in the cyber space. The study intended to explore this phenomenon, its degree of presence and identify whether population is a determinant variable or not.

Factor analysis is frequently used to analyze and extract observation on the main factors that relates to the phenomena.

3.2 Study Population:

The study included all the cities of Eastern Province that has 15000 population or more, excluding two cities. These cities are Al-Thoqubah which is part of Al-Khubar and the indices related to it interchangeable with Al-Khubar. Second city is Al-Oyun which has show high interference in search engine from another city with the same name in Moraco. This will limit the study population with 25 cities which will be the cases studied against 9 variables as show in below matrix.

3.3 Data Collection and Variables:

The goal of this section is highlight the data collection methods and the 8 variables that will be used to explore virtual presence of each city. Each variable will be explained to introduce them as contemporary means of analyzing cities on the cyberspace.

3.3.1 Population:

This study assumes population is a determinant variable in the virtual presence of cities due to the city residence contribution to the internet content. The study will test this hypothesis against the presence of Eastern Province cities in the search engine by the level activities either provided by non-residence like news targeting the cities residence or by the citizen's interaction about their cities in the cyberspace.

3.3.2 Google Search Engine City Frequencies:

Among all the famous search engines Google is the only one has (.sa). At the same time Google is the highest visited search engine in Saudi Arabia. It is ranked the 3rd, 6th, 11th and 16th among the highly 46 websites visited in Saudi Arabia (CITC, 2009). The CITC (who is) records show the domain has been registered in 11-01-2004 with physical representation in Riyadh Saudi Arabia (CITC S. N., 2009). Hence, the Saudi Google is selected to be the search engine of this study as it is expected to provide more local content than others. On the search the restricted searches on the exact wording or phrase like "Dammam City". In addition, the Arabic language was the only language used in searching the cases. The search result appears against the researched case will be inputted in the Google search filed for the subject city. The result indicates the number of times the city has inputted in the web content and Google search engine where able to identify it.

3.3.3 Google Groups

Then similar steps with restricted search phrase like "Al-Dammam City" will be used for Google groups search. The presence of the city name on the groups search engine represents an individual interaction about the city mainly from people living in the city or people targeting cities residence. It can be considered as the interaction of the residence in the physical space through the cyberspace. This represents a duality of interaction and substitution to the face to face interaction.

3.3.4 Google Blogs Search

Similar to the groups however it differ in the mean of interaction which is based on an individual more than a group that allow individual broadcast his ideas and thoughts. It is a kind of an individual expressing himself and interests to others. This virtual media can be considered as leverage of individual to communicate to others reflecting their virtual or physical activities on the cyberspace.

3.3.5 Google Images Search

Another side of Google search engine however, it focuses only on the images about the city and their residence activities. It provides more focus representation of the duality between physical virtual. This web content take pieces of the cities and their residence activities to the cyberspace.

3.3.6 YouTube Search

Represent a transfer of interaction of cities residence from face to face story telling or events attending to virtual means. This interaction delimited the time as it can be seen at any time and distance as it can be watched of being online at any physical space. During the data collection it was clearly observed that these virtual activities are merely individuals not institutes or business.

3.3.7 FaceBook Groups, People and Events

Facebook allows different individuals and groups to network with other users who can join each other networks. It also allows privacy settings on basis of networks. Groups are used for discussions and events etc. Groups are a way of enabling a number of people to come together online to share information and discuss specific subjects. While, Facebook events are a way for members to let friends know about upcoming events in their community and to organize social gatherings in relation to their physical content.

3.4 Study Cases and Variables

The following table show a matrix of the studded cities ranked according to the population size. The matrix indicates the raw data before applying the correlation factors and indicates only frequencies. On simple stastsics the indication show lead to large city population indicates higher we content.

Case Number	City	Population	Google Search	Google Groups	Blog Search	Images	YouTube	Facebook Groups	Facebook People	Facebook Events

Table 3.2 Correlation matrix, Determinant = 1.37E-005 which is 0.0000137

3.5 Populating the Correlation Matrix

The correlation matrix below show the top half of the table contains Pearson correlation coefficient between all pairs of variables whereas the bottom half contains the one-tailed significance of the coefficients. This matrix will be used to check the pattern of relationships. Fist, the significance value of the majority values is less than 0.05 in exceptions to three relations which are blog search with Google search, YouTube with

Google Search and face book with YouTube. The second verification will be by scanning the correlation coefficients which should be less than 0.9. This found only in one relation between Images and Google search. Finally since the determinant value is 0.0000137 which is slightly greater than the necessary value of 0.00001, the multicollinearity is not a problem for the collected data. Based on the three verification factors, the variables in the above correlation matrix correlate fairly well. And only one of the correlations is slightly large. Therefore, there is no need to consider eliminating any variable at this stage.

On the KMO and Bartlett's Test, a value close to one indicates that patterns of correlations are relatively compact and so factor analysis should yield distinct and reliable factors. Furthermore, values greater than 0.5 are acceptable (Kaiser, 1974), it has be described as mediocre value which ranged between 05 and 0.7 (Hutcheson and Sofroniou, 1999). For the eastern province cities cyber data the value is 0.578, which fall in the range of mentioned earlier. Based on that factor analysis is appropriate for these data. Likewise, Bartlett's measure the significance value less than 0.05 and therefore factor analysis is appropriate.

Kaiser-Meyer-Olkin Measure of Sampling Adequacy.		.578
Bartlett's Test of Sphericity	Approx. Chi-Square	3.932E3
	df	36
	Sig.	.000

Table 3.3 KMO and Bartlett's Test

3.6 Factors Extraction

Three factors are extracted before extraction, after extraction and after rotation. Before extraction identified 9 linear components within the data set which are the originally entered variables. Whereas factor 1 in the initial eigenvalues and after extraction, explains the variance by 58% with 83% cumulative with second factors. While first factor explains 51% of the variance with 83.1% cumulative with the other two factors. The significant finding of the matrix above is that the first factor considered the most important as it explains the variance by 51% in the rotation loadings.

Component	Initial Eigenvalues			Extraction Sums of Squared Loadings			Rotation Sums of Squared Loadings		
	Total	% of Variance	Cumulative %	Total	% of Variance	Cumulative %	Total	% of Variance	Cumulative %
1	5.217	57.967	57.967	5.217	57.967	57.967	4.563	50.695	50.695
2	1.222	13.580	71.548	1.222	13.580	71.548	1.553	17.257	67.953
3	1.039	11.546	83.094	1.039	11.546	83.094	1.363	15.141	83.094
Extraction Method: Principal Component Analysis.									

Table 3.4 Total Variance Explained

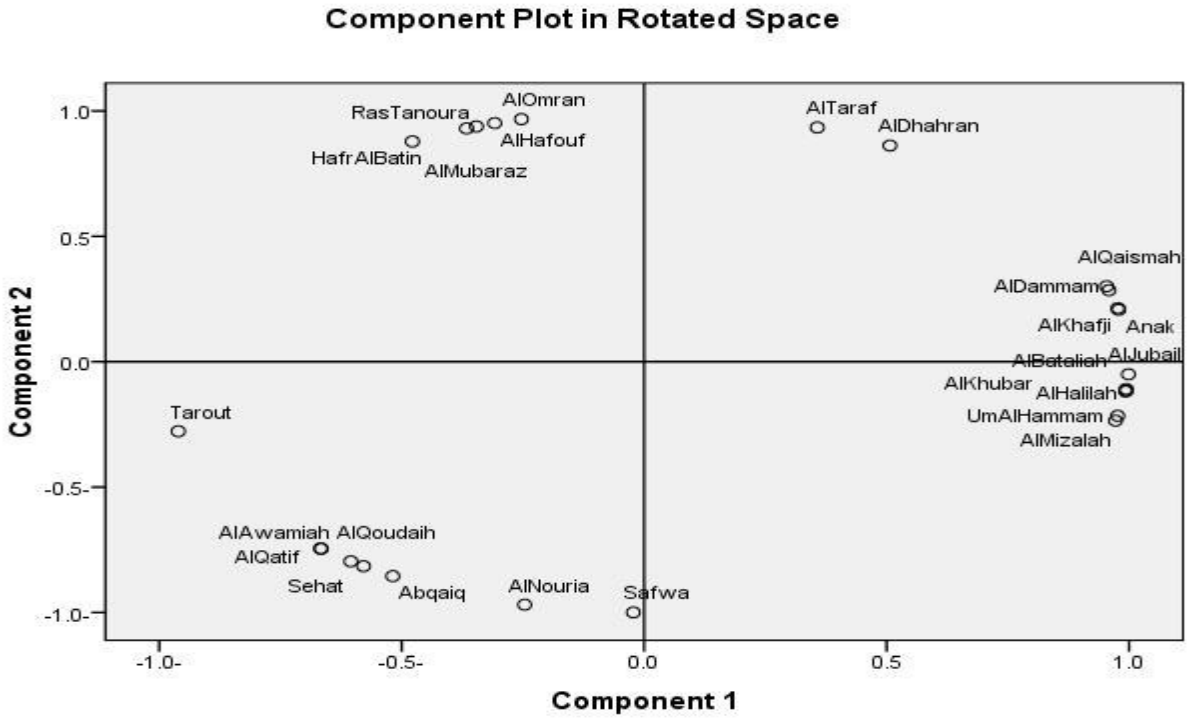
3.7 Rotated Variables Component Matrix:

The below table show the rotated factor matrix which represent the factor loadings for each variable onto each factor. It is important to note that loading less than 0.4 have not been displayed because it has been suppressed. In addition, the output has been set in SPSS to be sorted by size.

	Component		
	1	2	3
Google Images	.939		
Google Groups	.932		
FaceBook People	.920		
FaceBook Events	.772		
FaceBook Groups	.753	.573	
Blog Search	.703		
YouTube		.968	
Google Search			.949
Population	.548		.580
Extraction Method: Principal Component Analysis. Rotation Method: Varimax with Kaiser Normalization. a. Rotation converged in 4 iterations.			

Table 3.5 Rotated Component Matrixes

The above matrix indicates there are three factors affect the diffusion of cities in the cyberspace. The variables that load highly on factor 1 seem to all related to citizens interaction in the cyberspaces as substitution to the face-to-face physical interaction. It should be noted that, population has the least loading which indicates the less relevance of population size to the city cyber presence. Only to variables load to factor 2 which are YouTube and face book groups. While Google search and population load highly in factor 3 with less load value for population. These phenomena re-enforce the low relevance between city population and its cyber presence.



4 CITIES RANKING ACCORDING TO THEIR VIRTUAL PRESENCE

This stage of the study identifies the ranking of eastern province cities according to their virtual presence in relation to Factor 1 and 2. It clearly indicates that city size is not a significant factor on cities virtual presence. However, the virtual activities that relates to cities residence interaction are determinant factors in cities variations. The figure below indicate that cities that has high ranking scores in relation to Factor 1 in which Jubal tightly attached to highest score of factor 1.

This highlights the virtual cities equalities differ in the cyber space from the actual space. Various causes might lead to like distance viruses virtual interaction and cities human capital contrition to the web content. Despite the time limitation of this study, it shades light on new diminution in analyzing urban phenomena of actual cities from their virtual peripheries in the cyberspace.

5 CONCLUSION

This study attempted to study the phenomena of virtual cities in the Eastern Province in Saudi Arabia by relating their population size to their presence on the cyberspace. We explored the virtual presence of cities in the cyber space to indicate the significance of their cyber presence in relation to their population size.

Factors related to residence interaction in the cyberspaces as substitution to the face-to-face physical interaction seem to be the main determent in cities virtual presence. The statistical analysis indicates that the hypothesis of population is a determinant variable in the virtual presence of cities due to the city residence contribution to the internet content is rejected.

The significance appears by the virtual activities of the city residence that relates to cities residence interaction are determinant factors in cities variations. This highlights the virtual cities equalities differ in the

cyber space from the actual space. Despite the time limitation of this study, it shades light on new diminution in analyzing urban phenomena of actual cities from their virtual peripheries in the cyberspace.

It is suggested that researchers start seeking new methods in analyzing cities on the regional level by measuring the residence physical activities in relation to their virtual activities. The virtual activities of cities residence can be used as enablers of development and should be leveraged as emerging resources in regional development.

Improving intermodal transport with a focus on long distance: Selected findings from LINK –the European Forum on Intermodal Passenger Travel

Patrick Hoenninger

(Dipl.-Ing. Patrick Hoenninger, ILS - Institute for Regional and Urban Development, patrick.hoenninger@ils-research.de)

1 ABSTRACT

Intermodality, which describes both a quality of the transport system and a policy objective, has evolved over the recent years into a key word for the European transport policy and also some national transport policies. However, whereas intermodality in freight transport is being promoted with concrete support and initiatives on national and European level (e.g. Marco Polo programme), it has not yet received the same attention in the passenger sector.

The LINK project has created a European Forum on Intermodal Passenger Travel in order to enhance the combined use of different transport modes on a single journey. The project - launched in April 2007 - is funded by the European Commission (DG Energy and Transport) within the 6th Framework Programme. The intention is to sustain this platform after the 3 years funding period[1].

The LINK Forum puts the focus on long distance passenger transport[2] but including the "first and last mile". While urban intermodality has been made a topic in many initiatives, so far the long distance dimension, often also border-crossing, has not been sufficiently addressed. Trips over long distances only have a small market share in terms of total trips but account for a remarkable share of person-km[3]. They are of significance due to their economic importance, their high ecological impact and their above average rate of growth (mainly due to the development of low cost airlines).

Within the LINK project different thematic working groups of experts from across Europe developed the basis for recommendations on selected key challenges which should be tackled in order to enhance significantly intermodal transport. The recommendations target policy making as well as practical implementation on European and also on national level and refer to various fields of intervention.

2 PULL & PUSH STRATEGY FOR BUSINESS TRIPS

Making LINK's findings concrete, a strategy about the segment of business trips and job related mobility will be explained more in detail: its driving forces and context conditions, related to recommendable improvements on the one hand, and concepts for concrete measures for travellers on the other hand, mostly bridging the not sufficiently integrated long distance elements of intermodal trip chains.

The objective is to reduce monomodal car use for business trips and achieving a shift towards inter- and multimodality by calling upon companies' corporate social responsibility and by taking 'soft policy' actions to influence the regime of business trips within companies and institutions (pull factor). An important complementary lever to create supporting framework conditions is taxation regulation for company cars and reimbursement rules for (private) car use for business trips (push factor).

2.1 Relevance of the business travel segment

Constant car availability can be considered as one of the strongest reasons for habitual car use. Once established, behavioural habits are not easy to change[4]. Under these circumstances, no active choice between different transport modes can be expected. So the opportunities for fostering intermodality are further reduced. Car-based business mobility requires much less organisational effort than multi- and intermodal

[1]More information about the project: cf. Hoenninger 2008 and the project website www.LINKforum.eu

[2]Refering to trips of length >100 km (KITE), but neglecting the difference between network distance and crow-fly distance (average detour factor in some European countires: 1.3; KITE). Although intercontinental travel is not excluded in principle, it is not in the focus either.

[3]The survey on long distance travel in Germany (INVERMO) comes to the summary for the according market or travel behaviour "few are travelling a lot" (50% of long distance journey made by 10% of the population >14 years; Zumkeller et al. 2005: 72f).

[4]There are sufficient research results highlighting the importance of car-ownership and (permanent/ often) car-access for a car-oriented transport behaviour.

mobility[5], thus needs organisational support, which can be wrapped in the comprehensive approach of mobility management.

Business trips are understood as all trips made by employees or free-lancers of a company or (public) institution, which have the purpose to perform activities on behalf of the employer (i.e. regular commuting trips to/from the workplaces are not included).

Business trips account for a remarkable share of the transport market[6], and they show an increasing tendency[7]. In Germany, for example, 17% of all long distance trips (>100 km) are business trips (average 1.3 business trips per person and year). They are made by 12% of the population (>14 years) which actually makes long distance trips (INVERMO study; Zumkeller et al. 2002). Business trips in general have increased in the last decades by number, but more significantly by distance[8]. The majority of business trips are made by jobholders, and mostly by those with permanent access to a car. This is corresponding with the different opportunities to somehow "officially" use a car for business purpose, which makes a share of 1/5 of all registered motorised passenger vehicles (see table 1). In addition to the existing fleet, a major share of new cars is registered for business purpose or by businesses[9]. Controlling these will effectively affect the fleet as a whole.

type of usage / *type of registration*	private only	private + business	business only
private car	78,3 %	15,1 %	0,5%
company car (free-lancer)	0,2%	1,7 %	0,0%
company car (employer)	1,2 %	1,9 %	0,5%

Table 1: Cars in Germany by type of registration and usage (INVERMO 2005)

Next to the share it has to be pointed out that business trips follow other "rules" than trips for private purposes or trips by privately owned cars, mainly due to possibilities for tax relief. Financial instruments and their reform have indirect, but massive impact on the transport behaviour (modal choice), but are even more relevant on the strategic level concerning car ownership. Next to the ease of car purchase there is a nexus to the dual usage of company cars for private purposes: Fuel is often paid by the company. Taxation makes this appealing both for the company/employer and the beneficiary, whereas car-alternative modes partially have unequal, less favourable conditions. Taxation policy is thus very relevant for achieving strategic political objectives. In particular the EU objective on mitigation of CO2 has to be mentioned (reduction of CO2 emission in new cars 2008-2010 to 120 g/km with regard to the Kyoto objective)[10].

In addition to taxation and financial aspects, the modal choice is driven by the reputation of car drivers ("big cars = prosperity"). This recommends breaking up the circle of favourable taxation for "big" cars with high emissions and the degree of incentives and additional tax benefit for employees (business travellers).

2.2 The Concept

The recommendation is a complementary pull and push strategy to increase the share of and the market demand for inter- and multimodal business trips. Currently, long distance business trips are predominantly

[5]A company car offers permanent mobility with "flat rate" costs in contrast to the effort (transaction costs) to buy a train ticket - as backbone - and additional services (e.g. ticket for local public transport).

[6]An overview for some European countries is given by the FP6 project KITE (Knowledge Base for Intermodal Passenger Travel in Europe), see www.KITE-project.eu, particularly Collet/Kuhnimhof 2008. A close exchange between the networking and policy centrered project LINK and the more research oriented project KITE was given within the partial parallel duration.

[7]Increase of number of business trips 2004-2007 by 14% (companies and public institutions with ≥10 employees in Germany; VDR 2008)

[8]1982 - 2002: increase of trips by 14 %, increase of distances by 2 Million pkm or by 50 % (Germany-wide survey MID 2002; own calculation)

[9]In Germany (2007): 62% (Kraftfahrt-Bundesamt); 50-70% of new car sales in UK; high market shares also in The Netherlands and Sweden (OECD/ITF 2008, p. 13).

[10]A reform of the taxation related to car-use and car ownership - not only for business purposes - is an issue on European scale (e.g. EC 2002, EC 2005, TNO 2006), but also for initiatives on national level (FÖS 2008).

monomodal trips by car[11]. The recommendation aims firstly at reducing monomodal car-usage by suitable intermodal offers within a mobility management approach and secondly at changing the vehicle fleet for the still necessary business trips (company car) by taxation. In particular the segment of short long-distance trips (100-400 km crow fly trip length) needs more attention, as it offers a high potential for intermodality. Furthermore, the market segment of long or intercontinental trips is not directly put in the focus as the modal choice leads to aviation "by nature". However, the use of other modes to the airplane comes back to intermodal issues. Resrach covering business trips made by plane seems to focus solely or too much on the long distance leg (e.g. Beaverstock et al. 2009). Concenring intermodal long distance travel, in particular the air-rail combination (especially high-speed rail) attracted much attention from both research and policy making[12], whereas other modes are taken for granted.

There are factors that restrict the potential shift from car to other modes. Beside subjective attitudes, the purpose of a trip and the related luggage transport can be limiting factors[13]. Therefore, service branches (consulting, customer training, R&D) are best suited for intermodal travel as they often have to carry only portable computers, paper/print material but no heavy tools and machines.

2.2.1 Pull-factor Mobility Management

Companies and institutions elaborate and implement the pull-factor. Given their role as employers they are the relevant decision-makers concerning business trips by travel management[14] and, if existing, fleet management policies as travel decisions are made to a larger extent not by the traveller him- or herself compared to other purposes. Decision-makers have the opportunity to support sustainable mobility by corresponding rules for business travel[15] within a broader corporate social responsibility (CSR) policy. Public institutions have a particular role as travel directives of companies are often following them. Organising business trips should consider more often alternatives to the car[16]. Mobility management aims at fostering car-alternative modes and at influencing attitudes and behaviour towards sustainable and inter-/ multimodal travelling on business trips. Currently, mobility management is applied primarily on a site-based or local level[17]. But it can and should be extended to long distance (business) trips. Benefits can be both direct (e.g. financial[18]) and indirect (societal) benefits[19]. Its acceptance can be improved by demonstrating the benefits, in particular possible saving both for employers and employees.

Mobility management requires making companies and institutions aware that they are part of the transport system. The general idea is to better match the supply and the demand side with the aim to improve the conditions for the users of transport system and at same time increase the yield impacts of providers (e.g. increased demand for services). In order to achieve a shift towards inter-/ multimodality, suitable services for business trips have to be further developed[20]. The need for improvement particularly for business trips is highlighted by a study which assessed – amongst other aspects – the usage of transport services by trip purpose in Germany (Eck/Starck 2007). It resulted in worse ratings for long distance trips for business purpose and for commuting including educational purpose in contrast to shorter trips (see table 2). The

[11]In Germany, 76% of the long-distance business trips (>100 km) are made by car, 12% by rail, 9% by plane (INVERMO 2005).
A state of the art review of transport research concerning business trips found, at least for Germany, only little empirically based knowledge (Sauter-Servaes 2007).

[12]The European Commission launched e.g. the Rail Air Intermodality Facilitation Forum (RAIFF). One of many studies on this modal combination: Bozzani/L'Hostis 2006.

[13]In Germany, a study by DLR examined in-depth the circumstances and constraints and revealed that the car-use is higher the smaller the company is in terms of numbers of employees (Menge/Hebes 2008).

[14]Car policy is the according instrument reflecting the narrow perspective, determining company car use e.g., the car category for each level of hierarchy or level of incentive. An example for special journals showing the technical way of thinking in this sector is the German journal "Flottenmanagement" (www.flottenmanagement-verlag.de).

[15]In Germany, 90% of all companies have a company travel directive; the average in Europe is 75% (VDR 2008).

[16]In Germany, 18 % of the long distance business trips are resulting on considering other modes than the one chosen on a reporting day (average: 13 %; INVERMO study – Zumkeller et al. 2005).

[17]Numerous projects have been fostering MM; one of the most recent projects on European level was the project "MAX Successful Travel Awareness Campaigns and Mobility Management Strategies" (www.max-success.eu).

[18] > 50% of the costs for business trips are those for transport (example Germany, data 2006/2007, VDR 2008).

[19]Referring to the concept of CSR which is often embedded in Eco-Management and Audit Schemes (EMAS). The toolkit of the alternative German transport association VCD has been developed with this background.

[20]The relevance of improving services including their reputation is shown by the result of a survey assessing the quality of business trips >100 km in Germany (Nordlight research 2007; N=500) which rates rail worst in contrast to car and airlines (excellent & very good: rail 23%, car 45%, air 51%).

relevance of improving services including their reputation is also shown by the result of a survey assessing the quality of business trips >100 km in Germany (Nordlight research 2007; N=500) which rates rail worst in contrast to car and airlines (excellent & very good: rail 23%, car 45%, air 51%).

[N=2500]	commuting, education	business	leisure	vacation	shopping
within city	69%	59%	67%	-	70%
within region <100 km	62%	58%	62%	59%	62%
domestic >100 km	47%	50%	62%	59%	-
abroad	42%	43%	56%	58%	-

Table 2: share of respondents assessing usage of transport services good or very good (regardless mode) (Eck/Starck 2007)

Approaching transport services for business trips must not exclude car-based services. Car-sharing fills the gap between owning and occasionally using a car, but further efforts to meet the needs of business travellers are required in order to gain momentum[21]. Various offers have been developed targeting business travellers such as lounges at major railway stations, WLAN hot spots in stations and on board of trains, corporate portals of national railways, special advertisement. This shows that the needs of this target group are reflected by different operators and vendors. However, a wider thinking is required in order to adapt and improve suitable transport services that offer alternatives to monomodal car-use[22]. Mobility management for business trips can only enfold its potential if the relevant players are involved, i.e. particularly the national railway companies and suitable transport service providers. Associations like chambers of commerce, business associations, but also user associations, which are influencing companies by expertise and advice, can be involved in implementation[23].

A particular segment are business trips to business related events. Numerous events take place in cities, different in size (number of visitors), timing and duration, location, frequency, etc. A large number is dedicated to business purpose (e.g. fairs, conferences), some for both the public and businesses. For many visitors an event is often related to travelling to an unkown or only little known environment with a high demand for information, usually combined with high time constraints. The objective thus is to offer integrated low-thresholds services, which are perceived by visitors as pleasant, easy, fast, cheap and door-to-door and best appear as an integral part of event information and not as a separate information channel. Incentives for the intermodal journey should be included (e.g. receptions for businesses as “add-on” to the event), same personalised profiles of the traveller. It seems too early to predict the impacts of ICT based social (peer) networking tools like facebook, XING, linkedin on the further development of business vents, but already now a trend can be observed towards more relevance of informal networking in contrast to formalised presentations. Furthermore, booking of integrated packages of travel services, including the long distance trip chain, access to the event and to local transport (vouchers for public transport, taxi, public bikes etc.) are to be seen as promising offers. On a non-transport related level it can be said that supporting long distance travellers improves the event’s image and can be part of city marketing strategies.

Integrated mobility and event offers can actually be found, but so far often include very only limited information (e.g. airport connections) and even less ticketing options. Event visitors still have to make remarkable effort (e.g. visit several websites) to work out intermodal options if they do not chose comfortable monomodal car journey.

It is necessary to create forms of cooperation between the relavent stakeholders, from both the local and the long distance transport sector as well as from the side of event providers and additional parties (tourism industry). Expanding existing approaches of mobility management on the long distance target group of

[21]The Swiss car-sharing provider Mobility offers a variety of car types by a broad network of about 1200 terminals all over the country. The close cooperation with public transport associations (e.g. Zurich Region) results in appealing tariffs for users and raises the awareness for the offers vices versa.

[22]Flexible choice for business trips is offered in the Netherlands by the mobility card ‘Mobility Mixx’, which can be used for train, parking space at the railway station, ‘OV-fiets’ rental and the ‘train-taxi’. Private use is possible, but has to be taxed (employer has to monitor this). www.mobilitymixx.nl is a daughter company of a large car lease company, offering also comprehensive and tailor-made travel management.

[23]A good example in this respect is the toolkit of the transport user association VCD in Germany (VCD 2008).

business events seems promising as it requires "just" much more organisational effort than investment in technical issues. However, the question of purchasing remains open; different sales points (e.g. for long distance "leg", local transport, accommodation) may reduce the impact of joint information provision.

2.2.2 Push-factor taxation

On the "push-side", taxation concerning company cars can be a strong lever contributing on the one hand to multi- and intermodality and on the other hand to environmental objectives such as reducing CO2 emissions in the transport sector. The taxation of passenger cars should be re-designed in order to favour low emission cars, to treat all transport mode equally and to not support habitual car use. The rationale is that cars with (remarkably) less emissions and thus less fuel consumption compared to nowadays are a good chance to decouple prestige and incentive effects of (big) cars[24] and to introduce intermodal services according to the actual needs. This initiative includes essentially the free provision of fuel - often used also for trips for private purpose, and the according taxation. Often, provision of a company car and free fuel is more favourable for employees comparing to "normal" income (salary) in terms of taxation or contribution to social assurance.

National states governments elaborate and implement the push-factor taxation, as they are responsible for taxation. Nevertheless, the EU should try to influence national taxation to green company cars or a reform of car-related taxation. In terms of instruments it seems not appropriate to aim at launching a European directive with a long, difficult and open process without neglecting this strong instrument[25]. It is seen most promising to influence national policy-makers by clear recommendations on this complex issue. This includes highlighting the impacts of this lever, demonstrated by the forward-looking Member States.

2.2.3 Examples

The taxation of company cars in the UK is a role model for a change of the according policy: The benefit in money's worth for the private use of company cars is depending on the CO2 emission. The tax rate for petrol cars ranged from 15% of the list price for low emission cars (<140 g/ km) up to 35% for high emission cars (>240 g/ km). Diesel cars pay a 3% supplement to reflect local air quality emissions. This change of taxation policy resulted in the reduction of the number of company cars by 25% within 4 years[26]. Although an increase of use of private cars for business purpose has been observed, this is only partially compensation.

Additionally, in 2003 the company car tax fuel benefit charge was reformed. As consequence it can be observed that the proportion of company car drivers receiving free employer provided fuel for private use has also decreased significantly from 57% in 1997 to around 30% in 2005.

In contrast, the conditions in Germany are favourable for monomodal car-use: Taxation for private use of a company car does not take the actual fuel consumption or emission into account ("flat rate tax": 1% per month of the purchase price according to an official list, plus 0.03% of this value per km). This is similar to the company car tax system in the UK prior to April 2002 which encouraged employees to drive more business miles than they otherwise would have.

2.2.4 Discussion of implementation

The practical steps toward inter-/multimodality in companies and institutions need to be supported by "soft" measures which foster a modal shift from the monomodal car use.

Regulation concerning the usage of company cars is made on national level (legislation), but can and should be fostered by the EU by promoting convincing examples such as the British system and its financial and environmental benefits.

Within the LINK project, a consultation of stakeholders on LINK recommendations has been conducted. The overall agreement of about 200 stakeholders who took part resulted much more in agreement (79%) than disagreement (21%).

[24] In Germany, the average purchase cost of a company cars for CEOs is about 60 000 €, for the next management level about 44 000 € (Kienbaum 2008).
[25] Particularly the states with a strong lobby of car manufacturing industries (Germany, France) are very likely to oppose such an attempt.
[26] The number of company cars in UK was reduced to around 1.2 million in 2005 compared with around 1.6 million in 2001 (source: HMRC 2006).

Concnering the feasibility of this strategy it can be said that at the level of multiplicators strategic CSR and mobility management can rather easily be implemented, although it hast o be seen as a permanent task, which should be part of the corprate management.

The desired change of regulation should follow the existing examples of taxation like in UK, but will have to face political difficulties[27], i.e. strong counteract by car industry. A crucial open question is the application on existing fleets or just on new vehicles, which seems much more likley. The complexity of the recommendation is reflected in the results of the consultation, that the feasibility would be difficult (43%). Only a minority thought it could be done easily (18%).

The impact of this context condition is considered high due to the multiplier effect on companies and institutions. Changes need to be published (transparent reasons, easily to understand). In the consultation, a bit more than half of the stakeholders (55%) believed that this recommendation is crucial for enhancing intermodality (in contrast: 41% irrelevant or low, 4% counterproductive).

The timing for implementation depends on the political situation. The consultation resulted in almost equally 1/3 for short term implementation (<3 years), 1/3 medium term (3-5 years) and 1/3 longer term implementation (>5 years).

3 CONCLUSION

Intermodality is both a concept which receives too little attention by the stakeholders relevant for developing according services and by the travellers. The market segment of business trips and target group of business travellers respectively deserve being put more in the centre of reflections and efforts in order to serve by services offers which successfully tackle the inherent challenge to “get them out of the car”. But the market success depends on in how far these services are perceived suitable and convincing. Learing from decades of integrated transport planning (i.e. integrating all relevant field of intervention) it can be concluded that only a joint approach of “carrot and stick” can achieve the “old” objective of modal shift. Despite the concept of mobility management is well tested on local scale, also for the and together with companies and employers, it needs much effort in terms of organisation and powerful drivers (including figureheads) to enlarge it to long distance business travelling. The complex interrelation between car taxation and car use is perhaps outbalanced by the political implementation. But this lever is too strong to leave it out.

Innenstädte für alle: Visualisierung und Simulation zur Qualifizierung des innerstädtischen Entwurfs

Henning Stepper, Arne Siegler, Ingo Wietzel

(Dipl.- Ing. Henning Stepper, TU Kaiserslautern, Lehrstuhl Stadtplanung, stepper@rhrk.uni-kl.de)
(Dipl.- Ing. Arne Siegler, TU Kaiserslautern, Lehrstuhl Stadtplanung, asiegler@rhrk.uni-kl.de)
(Dr.- Ing. Ingo Wietzel, TU Kaiserslautern, Lehrstuhl Stadtplanung, wietzel@rhrk.uni-kl.de)

1 KURZFASSUNG

Die Revitalisierung der Innenstädte als den zentral gelegenen Teilräumen im städtischen Gesamtgefüge stellt eine der wesentlichen Zukunftsaufgaben der Stadtplanung dar. In den vergangenen Jahrzehnten fand ein tiefgreifender Bedeutungsverlust der Innenstädte als Zentren des Handels, der Kultur sowie des gesellschaftlichen Lebens statt, wodurch diese nicht mehr als Orte der Identifikation erkennbar sind, die eine Stadt nach Innen und Außen prägen und die das Image einer ganzen Stadt maßgeblich beeinflussen.

Die Herausforderung, die Innenstädte im Sinne der nachhaltigen europäischen Stadt als identitätsstiftende, urbane Zentren mit einem hohen Grad an Nutzungsmischung zu Revitalisieren, bringt eine große Zahl an zu berücksichtigenden Variablen mit sich, die untereinander in engen Wechselbeziehungen stehen. Vor diesem Hintergrund muss sich der Planende zur besseren Beurteilung und Einschätzung der gegebenen Rahmenbedingungen sowie der zu erwartenden Entwicklungen ein umfassendes Bild der Situation in den jeweiligen innerstädtischen Bereichen machen können. Hieraus ergibt sich neben der Notwendigkeit zur Darstellung der Rahmenbedingungen auch die Notwendigkeit zur fortlaufenden Visualisierung räumlicher Prozesse durch Simulation der städtischen Dynamik.

Auf dem Weg zu neuen Innenstädten als den Herzen von lebenswerten, gesunden und prosperierenden Städten liegen die Chancen im optimalen Einsatz sowie der zielführenden Weiterentwicklung bestehender Methoden und Anwendungen zur Darstellung der komplexen Rahmenbedingungen sowie zur Simulation räumlicher Prozesse und zukünftiger Entwicklungszustände im Kontext des innerstädtischen Entwurfsprozesses. Hierbei ist es zunächst von wesentlicher Bedeutung, die Ansatzpunkte zur Qualifizierung des Entwurfsprozesses zu identifizieren und daraus Handlungsfelder zum Einsatz von Techniken der Visualisierung und Simulation zu definieren.

2 EINLEITUNG

Im Rahmen der Schaffung von lebenswerten, gesunden und prosperierenden STÄDTEN FÜR ALLE sowie der Erhaltung deren Funktion als Zentren von Wirtschaft, Kultur, Kreativität, Wissenschaft und Innovation müssen die innerstädtischen Bereiche im Mittelpunkt allen planerischen Handelns stehen.

Innenstädte bilden seit jeher den räumlichen und funktionalen Kern der Städte aus, sind Konzentrationspunkte des gesellschaftlichen Lebens sowie hochrangiger zentraler Funktionen, deren Bedeutungsüberhang sich auch baulich durch hohe Dichten sowie prägende Stadtstrukturen, Gebäude und öffentliche Räume manifestiert (Ministerium des Innern und für Sport RLP [2006a]; S.10ff). In den vergangenen 30 Jahren haben jedoch tiefgreifende Veränderungen stattgefunden, die diesem Bild von der Innenstadt als unverwechselbarem und unersetzbarem urbanen Zentrum der Stadt entgegenstehen. Anhaltende Abwanderung von Wohnbevölkerung sowie weiterer charakteristisch innerstädtischer Nutzungen einhergehend mit der einseitigen Konzentration auf die Ansiedlung von Einzelhandelsbetrieben brachte eine Austauschbarkeit und Beliebigkeit der innerstädtischen Bereiche mit sich, das urbane Leben verschwand. Besonders stark vollzog sich die Abwanderung der Wohnbevölkerung in den Fußgängerzonen sowie den unmittelbar angrenzenden Bereichen, was zu starker Monofunktionalität und dadurch besonderer Krisenanfälligkeit dieser zentralen Lagen geführt hat. Diese Bereiche drohen, die innerstädtischen Brachen von morgen zu werden (Steinebach [2002], S.43).

Vor diesen Hintergründen sind die Innenstädte nicht mehr als Orte der Identifikation erkennbar, die eine Stadt nach Innen und Außen prägen und die das Image einer ganzen Stadt maßgeblich beeinflussen. Somit bildet die Reaktivierung und die Revitalisierung der Innenstädte eines der zentralen Aufgabenfelder der zukünftigen Stadtentwicklung (BMVBS [2007b]; S.3). Das Ziel, die Innenstädte im Sinne der nachhaltigen europäischen Stadt als identitätsstiftende, urbane Zentren mit einem hohen Grad an Nutzungsmischung zu Revitalisieren bringt eine große Zahl an zu berücksichtigenden Variablen mit sich, die untereinander in engen Wechselbeziehungen stehen. Gleichzeitig werden an keinen Raum der Stadt mehr Ansprüche von

unterschiedlichsten Akteuren und Akteursgruppen gestellt als an die Innenstadt. Somit bedarf die Umsetzung der oben genannten Handlungsansätze in jedem Fall einer individuellen, den Rahmenbedingungen vor Ort Rechnung tragenden ganzheitlichen, integrierten und partizipativen Strategie.

3 STADTPLANERISCHE HERAUSFORDERUNGEN AUF DEM WEG ZU INNENSTÄDTEN FÜR ALLE

Diesen Anforderungen muss auf der Ebene der Stadtplanung im Sinne der baulich- räumlichen Ordnung der Stadt entsprochen werden. Ausgehend von ihrer zentralen Aufgabe der zweckmäßigen räumlichen Verteilung sowie der wechselseitigen Zuordnung für die unterschiedlichen Nutzungsbereiche (Albers [2007]; S.31) steht die Stadtplanung der Herausforderung gegenüber, in einer zunehmend pluralisierten Gesellschaft mit verschiedensten, teilweise konkurrierenden oder sogar gegenläufigen, Ansprüchen und Bedürfnissen den Rahmen für eine in sozialer, ökonomischer und ökologischer Hinsicht ausgewogene Entwicklung der Gesellschaft zu schaffen (Albers/ Wékel [2008]; S.176). Somit liegt die Hauptaufgabe der Stadtplanung nicht mehr nur in der räumlichen Entwicklung der Stadt und im Umgang mit den Methoden und Instrumenten zu deren Steuerung sondern weiterführend auch in der Bewertung und Abwägung aller relevanter Ansprüche und Bedürfnisse. Die beabsichtigten und unbeabsichtigten Wirkungen geplanter Maßnahmen müssen im Idealfall bereits im Vorfeld abgeschätzt werden können, was insbesondere vor dem Hintergrund der immer komplexeren Rahmenbedingungen sehr große Schwierigkeiten mit sich bringt.

Basierend auf den vielfältigen Entwicklungslinien, unter denen sich die innerstädtischen Bereiche im Zuge individueller Differenzierungsprozesse in ihrer heutigen Prägung herausgebildet haben, wird die weitere Entwicklung der Innenstädte hierbei vom Umgang mit den Konsequenzen der aktuellen Rahmenbedingungen und zukünftigen Entwicklungstrends

- demographischer Wandel,
- gesellschaftlicher Wandel,
- Globalisierung und Ökonomischer Wandel,
- sowie Technologischer Wandel und Entwicklung zur Informationsgesellschaft

bestimmt werden (BMVBS [2009a]; S.11).

Ausgehend von diesen Entwicklungstrends lassen sich die wesentlichen Aufgabenfelder und Planungserfordernisse ableiten, denen die Stadtplanung im innerstädtischen Bereich gegenübersteht. Diese sind geprägt vom kleinteiligen und flexiblen Arbeiten mit dem Bestand, das unter Berücksichtigung der teilweise gegenläufigen Entwicklungstrends die integrierte Betrachtung und den Ausgleich aller Ansprüche an den innerstädtischen Raum sowie deren vielfältige Wechselbeziehungen zum Gegenstand haben muss.

- Wohnstandort Innenstadt stärken

Aufgrund des anhaltenden Bedeutungsverlustes der Innenstadt als Wohnstandort leben aktuell „nur noch 15% der Stadtbevölkerung mit Hauptwohnsitz in Stadtteilen der Innenstadt, 33% in Stadtteilen des Innenstadtrandes und 52% in Stadtrandbezirken“ (BMVBS [2009b]; S.18).

Um die Wohnfunktion der Innenstadt vor dem Hintergrund der aktuellen Entwicklungstrends und Herausforderungen zu stärken, ist es neben der zusätzlichen Anpassung und Erweiterung des Wohnangebots für die bereits schwerpunktmäßig in den Innenstädten vertretenen Lebensstilgruppen von wesentlicher Bedeutung, das Angebot an Wohnformen für Familienhaushalte sowie die wachsende Zahl älterer Menschen zu Diversifizieren und hinsichtlich Nutzungsverteilung, -dimensionierung und -zuordnung auf die Bedürfnisse dieser Bevölkerungsgruppen anzupassen. Neben der Anpassung an das gewandelte Nachfragerverhalten bildet der Erhalt sozialer Vielfalt und Kohäsion angesichts der zunehmenden Segregationsrisiken (BMVBS [2009a]; S.8) ebenfalls ein wichtiges Aufgabenfeld der Innenstadtplanung.

Vor den genannten Hintergründen insbesondere die Berücksichtigung der Wohnumfeldqualität und somit der weichen Standortqualitäten durch das Angebot möglichst vielfältig und abwechslungsreich gestalteter und strukturierter Quartiere sowie eines ausdifferenzierten Infrastrukturangebotes (Steinebach/ Feser/ Müller [2004]; S.63) ein wesentliches Handlungsfeld zur Stärkung der Innenstädte als Wohnstandort dar.

- Innenstädte als Zentren des Handels, der Dienstleistung und der Kultur reaktivieren und sichern

„Das Zusammenspiel von Dienstleistung, Handel, Kultur und Wohnen macht die Vitalität und Funktionsfähigkeit der zentralen Stadträume aus“ (BMVBS [2009b]; S.8). Vor diesem Hintergrund gilt es, die aus den innerstädtischen Ausdünnungsprozessen hervorgehenden Entwicklungspotentiale zum einen zur Aufhebung der Monostrukturierung zu nutzen und somit zum anderen durch die Schaffung neuer Umwelt-, Freiraum- und Erlebnisqualitäten die Städte als Zentren des Handels und der Dienstleistung zu sichern und zu attraktivieren. Hierbei muss das Angebot und die räumliche Verteilung der Handels- und Dienstleistungseinrichtungen stets die Versorgungsbedürfnisse einer pluralisierten und alternden Gesellschaft im Blick haben (Steinebach/ Feser/ Müller S.51).

Angesichts des Trends zu großflächigen Zentren des Fach- und Einzelhandels ist es hierbei von vorrangiger Bedeutung, diese Einkaufszentren anhand der Stellschrauben „Baukubatur und Dimensionierung der Einkaufszentren, Umfang der Verkaufsflächen, Branchen- und Mietermix sowie Einbindung in den Stadtraum“ (BMVBS [2009a]; S.8) verträglich in das innerstädtische Umfeld zu integrieren.

- Stadtstrukturen urbaner Dichte und Nutzungsmischung schaffen

Im Rahmen der Innenstadtplanung muss der mit den stattfindenden Entdichtungs- und Ausdünnungsprozessen einhergehenden Tendenz zur weiteren Funktionstrennung (Jessen [2007]; S.57) beispielsweise durch die Schaffung von Entwicklungsmöglichkeiten für Nutzungen, die aufgrund der Bodenpreisbedingten Monostrukturierungsprozesse der Vergangenheit aus den innerstädtischen Bereichen verdrängt wurden, entgegengewirkt werden. Die Entwicklungspotentiale müssen durch das „Zusammenführen von Wohnen, Arbeit, Handel, Bildung, Freizeit und ÖPNV“ (Kiepe [2007]; S.4) zur Schaffung urbaner, mischgenutzter innerstädtischer Bereiche im Sinne der europäischen Stadt genutzt werden, denn nur „Vielfältige und vitale Innenstädte stiften Identität, entfalten Attraktivität und Ausstrahlung für die Gesamtstadt“ (BMVBS [2009b]; S.8). Wesentliches Ziel bei der Etablierung urbaner Stadtstrukturen ist die Reduzierung der Verkehrsbelastungen in den Innenstädten, insbesondere des hohen Verkehrsaufkommens des Motorisierten Individualverkehrs. Die kompakte, nutzungsgemischte Stadt muss durch stadtverträgliche Verkehrs- und Mobilitätskonzepte unter „Aufwertung des Fuß- und Radverkehrs und die verstärkte Förderung des ÖPNV“ (BMVBS [2009b]; S.8) unterstützt werden.

Die zentrale planerische Aufgabe liegt somit im Erhalt und in der Schaffung von Multifunktionalität (Sander [2006]; S.11), wobei vor dem Hintergrund der demographischen und sozialen Rahmenbedingungen insbesondere den Bedürfnissen älterer Menschen sowie der Bevölkerungsgruppen mit Migrationshintergrund Rechnung getragen werden muss (Kiepe [2007]; S.4).

- Entwicklung und Bewahrung nachhaltiger, schöner Innenstädte

Angesichts des zunehmenden Standortwettbewerbs zwischen den Städten sowie der sozialen und ökologischen Herausforderungen, denen die Städte gegenüberstehen, muss im Rahmen des Stadtumbaus nach Wegen gesucht werden, die „räumliche Vielfalt durch Erhalt und behutsame Anpassung kleinteiliger Raumstrukturen sowie durch Aktivierung und stadtverträgliche Integration freier Räume und Flächen“ (BMVBS [2009a]; S.11) bei gleichzeitiger Bewahrung des Stadtbildes und der Identität stiftenden innerstädtischen Strukturen, zu gewährleisten.

Neben der Chance zur Schaffung von mehr Lebensqualität in den Innenstädten stellen die nutzungsgemischten, kompakten Kerne im Sinne der nachhaltigen europäischen Stadt aufgrund einen wichtigen Beitrag zum Ressourcen- und Klimaschutz dar, da sie nicht zuletzt dem flächenhaften Wachstum der Städte entgegenwirken und aufgrund des hohen Grades an Nutzungsmischung und Dichte einen erheblichen Einfluss auf die Reduzierung der Verkehrsbelastungen haben.

- Chancen der Entwicklung zur Informationsgesellschaft nutzen

Mit dem Wandel zur Informationsgesellschaft geht neben den technischen Neuerungen auch ein tiefgreifender Wandel hinsichtlich des Standortwettbewerbs einher, der durch die wachsende räumliche Flexibilität von Haushalten und Unternehmen geprägt ist. Gleichzeitig wird der Standort Innenstadt zunehmend für, meist solvente, Akteure aus den Bereichen Forschung und Entwicklung sowie der Kulturwirtschaft, was einerseits die Gefahr sich verschärfender sozialer Verdrängung mit sich bringt, (BMVBS [2009a]; S.11), gleichzeitig aber viele Chancen hinsichtlich der Revitalisierung und Profilierung

innerstädtischer Bereiche eröffnet. Aufgabe der Innenstadtplanung ist es hierbei, durch Schaffung flexibler Büro- und Gewerbeflächenangebote (Steinebach/ Feser/ Müller [2004]; S.55) optimale Entwicklungsmöglichkeiten bei gleichzeitig weitestmöglicher Konfliktminimierung zu gewährleisten.

Für den Wohnstandort Innenstadt ergeben sich ebenfalls vielfältige Entwicklungspotentiale bei-spielsweise als Wohnstandort für ältere Bevölkerungsschichten durch den verstärkten Einsatz von I&K- Technologien in den eigenen vier Wänden bei gleichzeitiger bedarfsgerechter Vernetzung mit Infrastruktur- und Versorgungseinrichtungen in unmittelbarer räumlicher Nähe zu allen relevanten Infrastruktur- und Versorgungseinrichtungen (Steinebach [2007]; S.22).

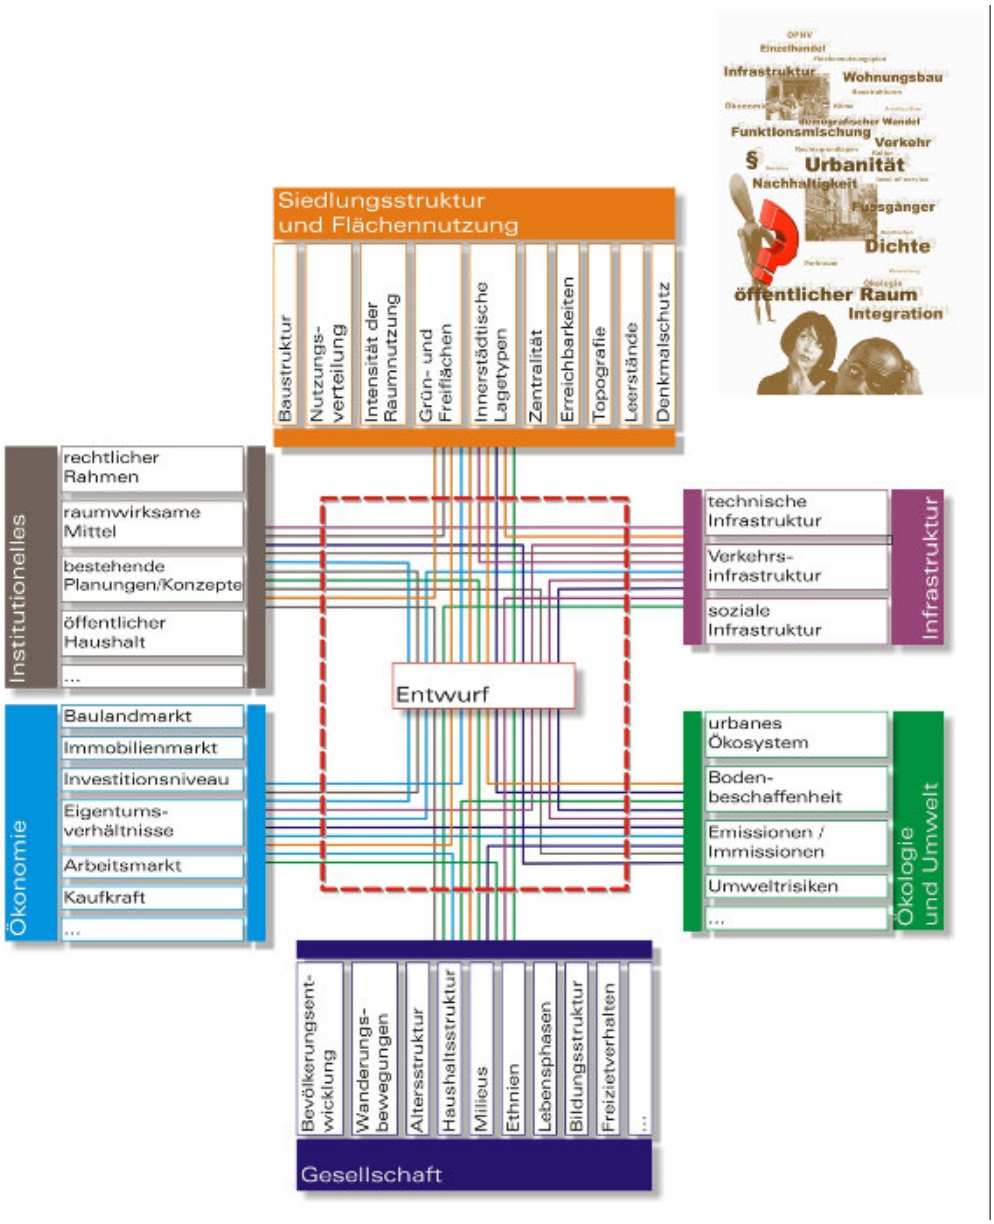

Abb.1: Einflussfaktoren im Rahmen des innerstädtischen Entwurfs (Quelle: eigene Darstellung)

4 STADTPLANERISCHES ENTWERFEN IM INNERSTÄDTISCHEN KONTEXT

Neben den Auswirkungen auf den gesamten Planungsprozess mit seinen formellen und informellen Planungs- und Entscheidungsabläufen beeinflussen die Handlungserfordernisse, bezogen auf die Innenstadt als zentralem Aufgabenfeld, insbesondere den konkreten Entwurfsprozess auf der Ebene der Organisation räumlicher Strukturen und deren Wechselwirkungen mit gesellschaftlichen Prozessen (Koenig [2006]; S.1). Das Erreichen eines bestmöglichen zukünftigen Zustandes stellt den Entwerfenden vor große Herausforderungen, die angesichts der zu bewältigenden Aufgaben nicht allein der „Unzahl koordinierter oder auch nur lose kontrollierter Einzelmaßnahmen in individuellen Entwurfsentscheidungen“ (Schalhorn/ Schmalscheidt [1997]; S.10) überlassen werden kann.

Im Rahmen des stadtplanerischen Entwurfs wird die Qualität der geplanten Räume anhand ihrer Eignung für die beabsichtigte Nutzung gemessen. Dies geschieht dadurch, dass typische Situationen mit dem Ziel eines schlüssigen und möglichst konfliktfreien zukünftigen Zustandes in Gedanken durchgespielt werden (Schalhorn/ Schmalscheidt [1997]; S.10). Gleichzeitig ist der Entwurf als die gedankliche / konzeptionelle Vorwegnahme noch nicht existierender Zustände nur sehr schwer in systematisierte Bahnen oder typologisierte Abläufe zu bringen (Bielefeld/ El Khouli [2007]; S.7), da ein Entwurf immer auch ein Ergebnis aus Abwägung und Gewichtung sein muss, die auf individuellen Entscheidungen und Einschätzungen basieren. Dies liegt an der Vielfalt an Lösungsmöglichkeiten, die sich im Entwurf für jede Problemstellung bieten und bei der es keine ideale oder beste Lösung gibt, die sich nach rein objektiven Maßstäben herleiten ließe, wodurch man vom Entwerfen als „bösartigem Problem" sprechen kann (Rittel [1969]; S.20). Während die Handhabung dieses „bösartigen Problems" beispielsweise bei der Realisierung neuer Siedlungen unter Wachstums-bedingungen noch verhältnismäßig einfach vonstatten ging, stellt sich die Situation angesichts der hochkomplexen Zusammenhänge in den innerstädtischen Bereichen grundsätzlich anders dar.

Somit ist es vor diesem Hintergrund von zunehmender Bedeutung, dem Entwerfenden bereits im Vorfeld ein möglichst umfassendes und alle Rahmenbedingungen berücksichtigendes Gerüst vorzugeben, in dessen Grenzen er sich bewegen kann. Vornehmliche Aufgabe dieses Orientierungsrahmens ist es, schon zu Beginn Handlungsspielräume zu erschließen und Lösungsräume aufzuspannen (Engelke [2002]; S.183), die sich aus der Vielzahl an feststehenden Parametern und Bestimmungsfaktoren ergeben, die den Entwurf beeinflussen und deren Vernachlässigung die Qualität des Entwurfes einschränken würde. Somit setzt ein tragfähiger stadtplanerischer Entwurf die eingehende Analyse der für die städtische Entwicklung relevanten Zusammenhänge sowie einen bewussten Umgang mit der Dynamik und den zeitlichen Eigenschaften von Prozessen voraus (Koenig [2006]; S.1).

5 VISUALISIERUNG UND SIMULATION DYNAMISCHER PROZESSE IM RAHMEN DES INNERSTÄDTISCHEN ENTWERFENS

Spricht man angesichts der sich wandelnden Rahmenbedingungen und den zukünftigen Herausforderungen von der Anpassung und Qualifizierung der Stadtplanung im innerstädtischen Kontext, so spielt der Einsatz von Informations- und Kommunikationssystemen, welcher die binäre Abbildung von physisch realen Prozessen zum Gegenstand hat (Steinebach [2005]; S.3), eine zunehmend tragende Rolle. Hierbei kommen die kommunikationstechnischen Anwendungsmöglichkeiten auf der prozessualen Seite, beispielsweise durch den ergänzenden Einsatz des Internets in Planungs- und Beteiligungsverfahren der Bauleitplanung (Steinebach/ Müller [2006]; S.7), zum Einsatz, während auf der materiellen Seite der Planverfahren die informationstechnische Komponente greift (Engelke [2002]; S.183).

Ausgehend von der zuvor genannten Notwendigkeit zur zielgerichteten Bewertung und Abwägung aller relevanten Ansprüche und Bedürfnisse sowie zur Abschätzung der möglichen Auswirkungen geplanter Maßnahmen stehen die informationstechnischen Möglichkeiten und Einsatzfelder zur Visualisierung und Simulation im Vordergrund.

Einhergehend mit den rasanten technologischen Entwicklungen ergibt sich eine nahezu unüberschaubare Menge an neuen Einsatzmöglichkeiten im Rahmen der Stadtplanung, zu deren Umsetzung eine Vielzahl an Methoden und Techniken zur Verfügung steht, die sich im Rahmen der Visualisierung vor allem durch weiterentwickelte Geografische Informationssysteme auszeichnet, durch die sich neben den herkömmlichen Anwendungsbereichen der raumbezogenen Datenverarbeitung in großem Umfang neue Einsatzfelder ergeben. In einer Web 2.0 basierten Welt mit einer ganzen Generation neuer Softwareprodukte und Anwendungen bei gleichzeitig unbegrenzter Daten- und Informationsverfügbarkeit wurde der Umgang mit raumbezogenen Daten, deren Analyse sowie deren Visualisierung revolutioniert (Hudson-Smith [2008]; S.8) was sich neben der wachsenden Bedeutung von dreidimensionalen Raum- bzw. Stadtmodellen, einer Vielzahl an Webmapping-Tools vor allem im Rahmen der Etablierung der so genannten „Neogeographie" (Eisnor [2006]) zeigt. Der unter dem Begriff Neogeografie stattfindende Wandel im Umgang mit räumlichen Daten abseits der herkömmlichen Methoden wird auch die Anwendungen zur Simulation städtischer Prozesse auf verschiedenen räumlichen Ebenen nachhaltig beeinflussen und zu deren Weiterentwicklung und/oder zur Synthese bestehender Methoden und Anwendungen beitragen.

Bezogen auf das Entwerfen im innerstädtischen Kontext ist es zunächst von großer Bedeutung, diese neuen Technologien und Anwendungen kritisch auf ihre planungsrelevanten Einsatzmöglichkeiten hin zu analysieren und daraus aus Planersicht Bedürfnisse abzuleiten (Berchtold/ Krass in: SRL [2009]; S.8), die den optimalen Einsatz sowie der zielgerichteten Weiterentwicklung bestehender Methoden und Anwendungen zur Darstellung der komplexen Rahmenbedingungen sowie zur Simulation räumlicher Prozesse und zukünftiger Entwicklungszustände ermöglichen.

So ist es beispielsweise durch den verstärkten Einsatz der Agumented Reality-Technik möglich, im Sinne einer Ergebnisvisualisierung sowohl Handlungsbedarfe in der Bestandssituation zu identifizieren als auch die visuellen Ein- und Auswirkungen von Vorhaben originalmaßstäblich, dreidimensional und in Echtzeit zu simulieren. Die baulich-räumlichen Auswirkungen eines Entwurfs im innerstädtischen Gefüge können durch den Einsatz der Augmented Reality-Technik visuell wahrnehmbar in der realen Umgebung vorab originalmaßstäblich abgebildet werden. Darüber hinaus ist es auch möglich, originär nicht visuell wahrnehmbare Informationen visuell abzubilden, beispielsweise Kaltluftströme oder Lärmimmissionen. Der Einsatz der Augmented Reality-Technik unterstützt als Alternative bzw. Ergänzung zum klassischen Zeichnen dementsprechend das Entwerfen an sich und darüber hinaus erfährt die Alternativendiskussion mit unterschiedlichen Akteuren eine entsprechende Qualifizierung. Neben den technischen Ausstattungen ist für den Einsatz der Augmented Reality-Technik ein virtueller, generischer Datenschatten notwendig, der ein digitales Abbild der Realität und der geplanten Vorhaben darstellt (Wietzel [2007]).

Diese und weitere Einsatzmöglichkeiten im Rahmen des innerstädtischen Entwurfsprozesses ergeben sich neben der Notwendigkeit zur Darstellung der Rahmenbedingungen und der Vorgabe eines Orientierungsrahmens auch aus dem Erfordernis zur fortlaufenden Visualisierung räumlicher Prozesse durch Simulation der städtischen Dynamik im Laufe des gesamten Entwurfsprozesses. Dies dient zum einen zur besseren Beurteilung und Einschätzung der getroffenen Entwurfsentscheidung und erlaubt zum anderen das kontinuierliche Qualitätsmanagement im Entwurfsprozess sowie im Ergebnis die bessere Beurteilungsmöglichkeit und Nachvollziehbarkeit der auf den verschiedenen Stufen des Entwurfsprozesses getroffenen Entwurfsentscheidungen.

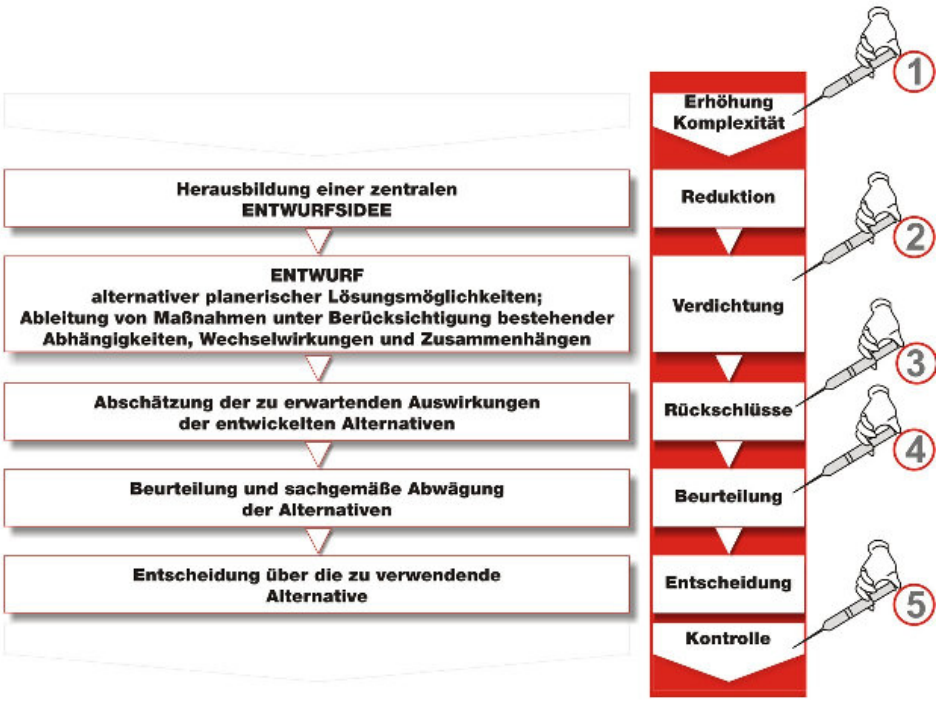

Abb.2: Qualifikationspunkte des stadtplanerischen Entwurfsprozesses durch Visualisierung und Simulation (Quelle: eigene Darstellung)

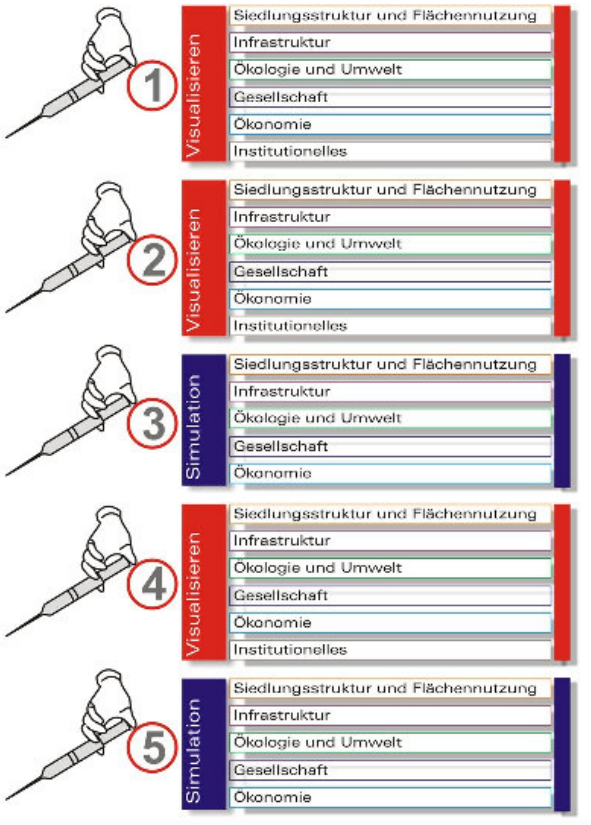

Abb.3: Einsatzfelder von Techniken der Visualisierung und Simulation anhand der identifizierten Qualifikationspunkte (Quelle: eigene Darstellung)

Zusammenfassend liegen die Möglichkeiten und Potentiale zur Qualifizierung des stadtplanerischen Entwurfsprozesses weniger im Finden abschließender Antworten oder im Aufzeigen konkreter Lösungen für ein gegebenes Entwurfsproblem als vielmehr im Angebot qualifizierter Instrumente zur Entscheidungsunterstützung sowie zur besseren Abschätzung und Beurteilung getroffener Entwurfsentscheidungen. Ausgehend von der grundsätzlich nicht objektivierbaren Entwurfsarbeit steht somit die Schaffung einer „objektiveren Subjektivität“ (Bielefeld/ El Khouli [2007]; S.32) im Vordergrund, zu deren Erreichen die informationstechnischen Möglichkeiten der I&K- Technologien in Form von Visualisierung und Simulation einen wesentlichen Beitrag leisten können.

Zentrale Fragestellungen, denen in diesem Zusammenhang nachgegangen werden soll, sind:

- Inwieweit können Methoden und Anwendungen der Visualisierung und Simulation die Qualität eines stadtplanerischen Entwurfs beeinflussen?
- Welchen Anforderungen müssen Methoden und Anwendungen der Visualisierung und Simulation zukünftig gerecht werden?
- Wo liegen Potentiale zur Weiterentwicklung und/oder zur Synthese bestehender Methoden und Anwendungen?

6 FAZIT

Auf dem Wege zur Schaffung von lebenswerten, gesunden und prosperierenden STÄDTEN FÜR ALLE sowie deren Erhaltung als räumliche und funktionale Zentren von Wirtschaft, Kultur, Kreativität, Wissenschaft und Innovation steht die Stadtplanung großen Herausforderungen gegenüber, die sich in den zentralen Handlungsfeldern der Innenstadtplanung widerspiegeln, die sich wie folgt darstellen:

- Wohnstandort Innenstadt stärken.
- Innenstädte als Zentren des Handels, der Dienstleistung und der Kultur reaktivieren und sichern.
- Stadtstrukturen hoher Dichte und Nutzungsmischung schaffen.
- Entwicklung und Bewahrung nachhaltiger, schöner Innenstädte.

- Chancen der Entwicklung zur Informationsgesellschaft nutzen.

Neben den Auswirkungen auf den gesamten Planungsprozess mit seinen formellen und informellen Planungs- und Entscheidungsabläufen beeinflussen genannte Handlungsfelder insbesondere den konkreten Entwurfsprozess auf der Ebene der Organisation räumlicher Strukturen und deren Wechselwirkungen.

Vor dem Hintergrund der Notwendigkeit zur Anpassung und Qualifizierung der Stadtplanung im innerstädtischen Kontext spielt der Einsatz von Informations- und Kommunikationssystemen zur zielgerichteten Bewertung und Abwägung aller relevanten Ansprüche und Bedürfnisse sowie zur Abschätzung der möglichen Auswirkungen geplanter Maßnahmen eine zunehmend tragende Rolle. Die Erarbeitung von Ansätzen zur Qualifizierung des stadtplanerischen Entwurfsprozesses durch Visualisierung und Simulation muss hierbei auf folgenden Ebenen des Entwurfsprozesses erfolgen:

- Visualisierung der gegebenen Rahmenbedingungen
- fortlaufende Visualisierung räumlicher Prozesse durch Simulation der städtischen Dynamik zur besseren Beurteilung und Einschätzung der getroffenen Entwurfsentscheidung
- kontinuierliche Qualitätskontrolle/ Qualitätsmanagement im Entwurfsprozess.

Bezogen auf die zur Verfügung stehenden Methoden und Techniken haben in den vergangenen Jahren tiefgreifende Veränderungen stattgefunden, welche die Möglichkeiten und Einsatzfelder zur Visualisierung räumlicher Informationen sowie zur Simulation städtischer Prozesse revolutioniert haben.

Hierbei ist es von besonderer Bedeutung, die Eignung der zur Verfügung stehenden Methoden und Anwendungen hinsichtlich ihrer Potentiale zur Qualifizierung des innerstädtischen Entwurfsprozesses zu analysieren und weiterführend nach Wegen zu deren Weiterentwicklung und/oder zu deren Synthese zu suchen.

1 ABSTRACT

MUVIS (Multidimensional Urban Visions) is an applied research project aimed to create an extensible platform for online participatory urban planning and multidimensional visualization. MUVIS will offer the people, local authorities, and investors a dialogue of all participants. In the Virtual Petrzalka case study we facilitate model creation and visualization as well as support discussion of urban visions and plans. MUVIS offers a recent technology solution, transfers the ideas from academy to practice and attempts to affect – in the best possible way – the future of our cities. Our ongoing project is supported from an EU structural grant scheme OPVaV-2008/4.2/01-SORO; with ITMS code 26240220009. In this paper we overview the methodology, technology, and digital content creation and presentation. We describe selected problems in Bratislava urban planning in the past and we discuss our approach.

Keywords: 4D visualization, urban planning, online presentation, virtual environment

Figure 1: Historic urban area visualizations: (a) left, a painted veduta of Bratislava, (b) right, a screenshot from Virtual Bratislava Navigation Tool by Stanislav Stanek. Aerial photo courtesy of Eurosense Slovakia, terrestrial photos by Matej Zeman. The popular painting from 18th century serves as a symbol for the old city, e.g. at http://www.bratislava.sk/.

2 INTRODUCTION

Bratislava (Pressburg, Posonium, Istropolis) belongs to those places in Central Europe where the urban development and phenomenon of genius loci [Norb00] suffered a lot from multiple historical and ideological discontinuities. One of the victims of urban deformations was the Bratislava Castle, visible in Fig. 1 in its old shape and from the aerial photo, dated 2003. In the year 2009, the archaeological research discovered an old Celtic castle underneath the current Bratislava Castle, probably – according to Austrian professor Werner Jobst - the lost Carnuntum [Mus10], the capital of the Noricum province, mentioned by Tiberius mission in written history - in the year 6. The castle building with its four towers, among others the favorite place of Mary Therese was destructed by fire in 1811. Considered as a symbol of feudalism, this ruined memorial without a roof and surrounding prominent urban area was not renovated until about 150 years later the fire. Next to the castle we can find probably the top anti-cultural damage of a historic old town – a highway between the Castle and the Coronation Church. The valuable historic urban area, an original place of history and local atmosphere, was cut by modern transport route built as a prolongation of a postmodern bridge. Despite these urbanistic atrocities, the biggest urban area under permanent public discussion is Petrzalka, illustrated in Figure 2. Petrzalka is a giant habitat built from the cheapest housing alternative – panel buildings. Its 150 000 population makes Petrzalka, so to say, the third biggest city in Slovakia. As the current urban disaster cannot simply be replaced, we hope to open a new communication channel for public

participation in its current and future urban development and improvement. The abovementioned context motivated our decision to choose Petrzalka as the study for the MUVIS project. Virtual model of Petrzalka will extend the existing virtual model of historic Bratislava southwards and MUVIS will be verified, tested, and evaluated using this urban database.

The alienation of modern architecture and urbanism is identified by many authors and public participation is often proposed as a promising alternative. MUVIS is an extensible platform for online participatory urban planning and multidimensional visualization. Exploiting a layered multidimensional content structure, aware of time and space in the virtual city, MUVIS users will share and co-author "The City as a Process in Time and Space" [Fers02]. At the CORP 2010 conference we present the current version of our solution.

The rest of the paper is structured as follows. We introduce the previous work, methodology and technology. In more detail, we present the project achievements and decisions. Finally, we conclude and discuss the future work.

Figure 2: Bratislava historic center is separated from Petrzalka by the Danube river. Petrzalka is a controversial urban area with many unsolved problems. The biggest and longest blocks of panel houses are nicknamed the Chinese Wall. One of the general solutions for the future urban development seems to be the public participation in decision making processes. (The whole area was subdivided into smaller areas for the purpose of model creation. Building our urban database starts with aerial images, rooflines and building footprints from Cadaster Portal of Slovak Republic. Aerial photo courtesy of Eurosense Slovakia.

3 PREVIOUS WORK

The planners of urban solutions search for shapes and functions on multiple scales, forming a new version of "urban text". However, there is no complex vocabulary of scales, shapes and functions, they are discovered and created ad hoc. There are lucky cases – as for example Graz, which is described by the UNESCO's World Cultural and Natural Heritage List: "The urban complex forming the historic centre of the city of Graz is an exceptional example of a harmonious integration of architectural styles from successive periods. Each age is represented by typical buildings, which are often masterpieces. The urban physiognomy faithfully tells the story of its historic development. Graz is a particularly fine example of the living heritage of a central European urban complex that was under Habsburg rule for many centuries. The old city is a harmonious blend of the architectural styles and artistic movements that have succeeded each other since the Middle Ages, together with cultural influences from the neighbouring regions." And there are unlucky case, one of which is Petrzalka, where the change causes alienation, anonymity, missing infrastructure and another entries on the long list of multidimensional damages.

The organicity of change and proportionality of shapes can be approximately measured using fractal geometry [Sali03]. We estimate the Waterfall by Wright induces a largely different measure compared to the Bratislava highway cut through the heart of the old town – placing the Coronation Church facade right next to everyday pressure of trucks, cars, and buses. The collective imagination in this case is not formed, but deformed. The first experiments with Bratislava fractal measurements arise in a PhD research project [Mesz10] at the Faculty of Architecture, Slovak University of Technology.

The city has, among other places (squares, riversides, streets, quarters), the city verticals, given by towers, memorials, silhouettes, rivers and wells (old water sources). The oldest known ancient algorithm for founding a new city has been preserved in Latin books. The founders of Rome were the Etruscans – "engineers" invited by the rural Romans who had no knowledge in the field. The Etruscans computed the city location, ploughed the city border around, erected the city tower to transcend the city to the sky and – nearby – they dug a mundus. The mundus was not necessarily a well. It was the root of the city, transcending the city downwards, into the earth and into the depth. (One can see in erecting and rooting the male and female principles.) The Etruscan language, being isolated from Indo-European languages, has been not preserved up to now. Despite the fact that we do not know the language, we have two fundamental Etruscan words in the international language – urbs (the city) and mundus (the world, the meaning was changed by the Latin users).

There are several well-known urban thinking milestones, for city creation [Vitr09], for its perception Lynch's Image of the City [Lync60]. His perceptual notions – especially imageability – express the readability, areas, squares, borders. Individual perception of a particular place, genius loci, has phenomenological explanation in [Norb81]. The place is, after Forte, the author of virtual museum definition [Qvor01], the opposite of an alienated space (e.g. hypermarket). The architectural alienation is discussed e.g. in [Bang07], the alienation of architecture and urbanism was studied e.g. by Rem Koolhaas, and socio-psychological problems of urbanism in [Mits69]. Bangs judges that the architecture missed classic craft in mastering proportions and preserving archetypes like cave, glade. The habitat (flat, house) should balance the needs for privacy and public space, which is not possible in noisy panel houses. Nowadays, nobody has a legal way to coordinate investors egoisms, which would lead [Mits69] to unthinkable limitation of private property rights. Therefore, long-term public participation (PP) is one of the experiments to overcome the alienation. The Aarhus Convention [Aarh98] is a new sort of an environmental deal, trying to harmonize both human and environmental rights [Jokl07, p. 73]. PP can be characterized as a forum for exchange of opinions, experiences, knowledge, organized to support communication of all segments, solving the specific problems in given area [Renn95]. PP can support social inclusion, better concurrency, social cohesion, environmental balance and public feed-back for decision making [Gave98]. PP classification and its computerized support is offered in [Jokl07, p. 73n] and PP is mandatory in Germany by law [Jokl07, p. 79]. The risky aspect of PP is that the public is not prepared for it. Therefore, MUVIS mission includes the technology enlightenment/evangelization part, as well. We distinguish GIS as a professional planning tool used for decision-making [Jokl07] from PPGIS (Public Participation Geographical System), combining methods and technologies, conveying interactive presentation of various alternatives of geospatial data, based on problem-oriented selection. A recent survey of PPGIS projects and dilemmas has [Kyem09]. Another alternatives represent geobrowsers (Google Earth [GooE09], MS Virtual Earth [MSVE09]), compared e.g. in [Lebe07], and VEPS (Virtual Environment Planning Systems) [Jokl07]. The functionality of each of the above alternatives necessarily covers file and database management, search and navigation in space, time, or semantics, calibrating, filtering and storage, versioning, urban database editing, multimedia presentation of ideas, feedback, comments, forum and voting subsystems. As they are VR systems, their architecture can be broadly subdivided into four categories scene graph, semantic database, generic system or distributed system [Guti07]

3.1 Cyber Cities

The vision of future internet outlines the Semantic Web [Bern01], requiring autonomous agents and globally built ontologies like CIDOC CRM [Crof05] for cultural heritage and [Jan09] for geodata. The cyber cities [VirC09] methodology started with a few chapters in [Leon00]. Work Flow Issues for automation analyzes F. Leberl et al. [Lebe00] in three parts 1. Aerial photogrammetry, 2. Digital canopy elevation model, and 3. Building geometry extraction. The Model Building Pipeline) is characterized by G. Roth [Roth00]: 1.

Callibration, 2. Acquisition, 3. Registration, 4. Point Creation, 5. Model Creation, 6. Model (Mesh) Compression, 7. Texture creation. Multiple modifications elaborated [Ferk04], [Lebe07], [Klei09], where even „ontologic scales " appear and from where the evaluation [Mose08] for virtual Berlin [VirB09] is inspired. MS Virtual Earth workflow is described in [Lebe07] as: 1. Surface Point Cloud, 2. Orthorectified Image, 3. Classification Map, 4. Bare Earth Topography, 5. 2.5D Textured Buildings. There are also experiments with procedural cyber city creation which can be used for less important city parts or in computer games where the exact model is not necessary. The goal of virtualization can be formulated as converting space into places, where place is defined by Christian Norberg-Schulz as "dynamic unity of architecture, population, and iteractions among them" [Came07, s. 337]. There are three levels of quality for virtual places 1. Visualization virtual places, 2. Activity-based virtual places, and 3. Hermeneutic virtual places – culturally coded places where one can hide himself, identify with, own or collect cultural objects (in our case visions, presentations, opinions). The fundamental double-book on semiotics for virtual reality is Virtual Space [Qvor01] and Virtual Interaction [Qvor02], whereas the VR technology seems to be best taught in [Guti08]. The alternative for W3C Semantic Web initiative are represented by digital libraries, e.g. Europeana [Euro09]. The quality measure for virtual museums can be found in [Came07], but a specialized cyber city reference and a generally accepted measure of the quality of virtual museums is stil missing. Obviously, the (low-level) geometric and radiometric errors in subspaces of 8D (x,y,z,t,r,g,b,alpha) state space can be evaluated using standard measurement or estimation methods. The complexity in the field is discussed in [Zara02].

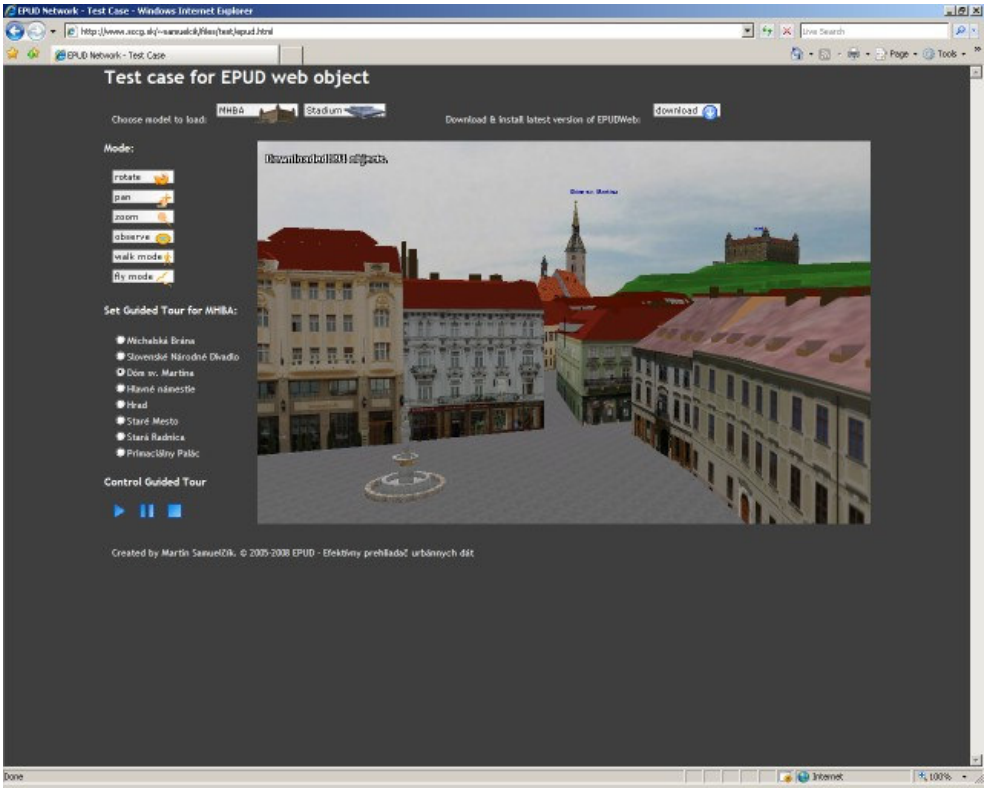

Figure 3: Historically, one of the first experiments to fly over virtual Bratislava using Microsoft Internet Explorer. The screenshot displays Bratislava Castle without vegetation and the Coronation Church tower as seen from the Old City Hall through Main Square. EPUD software tool used as web object here.

3.2 Virtual Bratislava

Chronologically, the development of Virtual Bratislava model and related methods can be traced back in time through multiple academic projects over a time span of about 10 years: MUVIS, Multidimensional urban visions (OPVaV-2008/4.2/01-SORO; 26240220009), Geometry Processing for Virtual Reality (VEGA 1/0763/09), Complexity of Geometric Algorithms for Realtime Rendering in VR (VEGA 1/3083/06), PM3Donline (AV 4/0023/05), EPUD (APVT-20-P05105), Natural Phenomena Visualization using Unstructured Grid (ASO SK-04-BA-010), STRAPAMO 18: MetropoVis, Virtual Heart of Central Europe (www.vhce.info, Culture 2000 n. 2003 - 1467/001/001 CLT CA12), Virtual Environments for WWW (VEGA 1/0174/03), Navigation and Cooperation in Virtual Environments - Virtual Bratislava (APVT 20-

025502), Advanced Methods for Virtual Habitat (Aktion AT-SK No. 323-6/2003), Computer Graphics and Image Processing Applications (VEGA 1/7666/20), and Multimedia Historic Bratislava DVD (MDPT 456/131/2005). These group projects were solved in accordance with tens of dissertations, master and bachelor theses [Beha08], [Dušk09], [Feki07], [Majo09], [Varh09]. The complete list of all coauthors includes up to 200 names.

In this paragraph we mention selected experience and/or results from the above projects, described more in [AMVH03], [Ftac07], [PMZA08], [Ferk09]. The first online 3D Bratislava models were cultural heritage highlights at [VHCE09], optimalized for IE (2004) [Ferk04], namely the Bratislava Castle, a National Cultural Monument and the well-known landmark (Figure 4), or St. Martin's Cathedral (also know as Coronation Church), a three-ships gothic church where 11 kings and 8 queens (including Mary Therese) were crowned between 1563-1830. The first Slovak virtual museum is specified in [Mrva07], [Ferk09] and published online [PMZA09]. As the real museum is in an old castle surrounded by a historic park, we also developed a method of park reconstruction using, to a certain extent, dendrological data [SmHe08], [Ferk09]. Laser measurements were needed for the Bratislava castle well reconstruction. Combining real data and hypothetic lighting scenario, we reconstructed the interior of Chatam Sofer Memorial, presented at [VHCE09]. For Multimedia Historic Bratislava DVD [Ftac07], [Boro08] we experimented with sound gallery for presenting the emotional history highlights and with a matrix-like organization of digital content – in one direction the memorials, city sights or themes and in the second direction, orthogonally to the first ione, the output media – photographs, videos, 3d models. The navigation thus becomes intuitive and idiomatic in sense of [Coop95] and even elderly people our novel multimedia kiosks can navigate quickly. The ideas from applied research project were combined with basic research findings – geometry processing using data-dependency [Toth06], mesh refinement [Noci07], specialized triangulations, false fundamental matrices for speeding-up epipolar reconstruction, extracting semantics from pictorial data [Šiku03],[Šiku06a], [Šiku06b], information visualization [Novo07], encrypting mutimedia data, video segmentation [Cern06], image-based and real-time rendering methods, reconstruction quality [Samu08], [Lack09], streaming, guided tours planning and empathic avatars [Stan09]. For presenting the past, we experimented with digital storytelling, which resulted into the discovery of LOD-stories [Pat10]. However, some problems remain open and the vision of a 3D xerox, i.e. an automatic conversion of input data into a cyber city or museum, requires much more efforts, ideas, and future work. For cybercity internet presentation the real-time rendering in an online environment seems to be the crucial one.

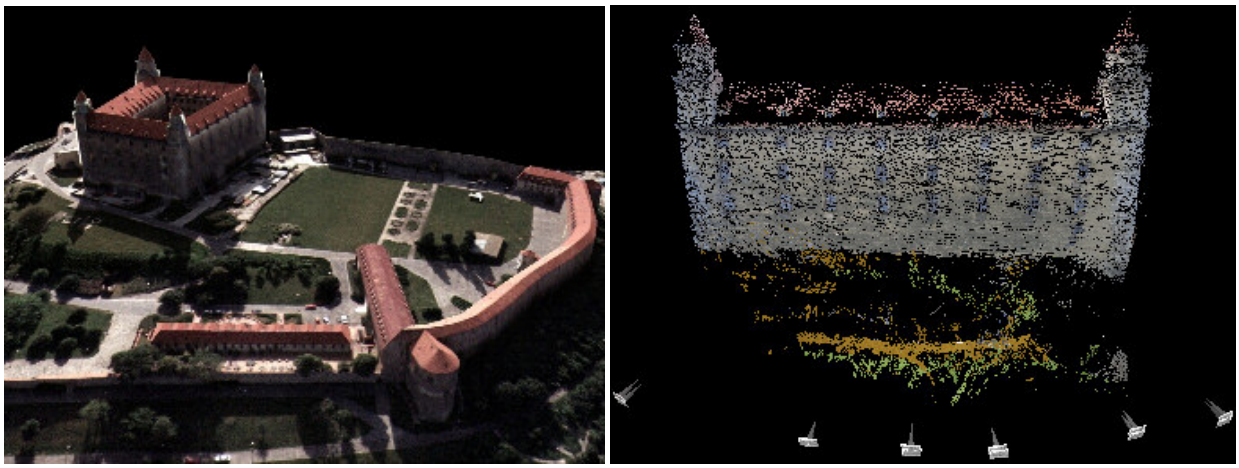

Figure 4: The first 3D urban models: (a) Castle reconstruction with the kind help of Eurosense Slovakia, provided by Peter Borovsky, and (b) the first MetropoGIS reconstructed castle façade by Stanislav Stanek. Input camera positions and the ghosts before their elimination are shown. By the way, the grass area in (a) covered the lost Celtic palace (Carnuntum?).

4 OUR APPROACH

We define our approach as a cooperative creation and evaluation of possibilities in geometric-semantic domain. It might seem natural to just adopt one of the existing PP GIS solutions, but the financial and legal situation in transforming countries differs heavily from established market economies. For short, there is neither legislative nor market prepared for cyber cities, virtual cultural heritage, digital libraries, or digitization of museum collections. The complete initiative in this segment comes from academy and EU

funding. This is the reason behind the obvious gap between functional virtual Berlin, Graz, or Vienna, already possible as everyday professional tool of respective divisions at city municipalities, and the striving virtual Prague, Bratislava, Budapest, Warsaw, Peterburg or Moscow, depending on academic projects and their (usually underfed) budget.

We identify three major target groups in the MUVIS project – authors, specialists, and public. Each of these groups comes with a different motivation, different skills and different information technology available. For example the latter are not well prepared for using modern information technology tools (e.g. we had to develop special urban reconstruction tutorials in Slovak for our own students [Ona07]). Wide public audience will share the MUVIS visualization and in given cases it will participate on urban planning forum. No special education is assumed and we can't count on a powerful hardware being used on their side either. These factors limit the amount of their active participation on creating or modifying the virtual space. The authors, on the other side, have the full access (passive and active) to the digital content and provide both the virtual working ground for the other two target groups and the administration of the project itself. They also maintain the database and develop future MUVIS version. The last group – the specialists – represent a force in the urban planning, coming either from the municipal administration domain or from the professional domain, such as e.g. architects, real estate developers etc. This group has a presumably higher level of experience than the general public yet still has not a limited access to the underlying digital content.

MUVIS cross-platform functionality necessarily covers file and database management, search and navigation in space, time, or semantics, calibrating, filtering and storage, versioning, urban database editing, multimedia presentation of ideas, feedback, comments, forum and voting subsystems for given localities. We combine two architectures - scene graph and semantic database to certain extent. Scene graph architecture supports the geometric criterion for visualization part. On the other hand, the urban database has to be constructed with respect to semantics. For possibly distributed memory system for preservation and storage of enormous datasets we take into account Bigtable [Chan06], proven in multiple similar projects, e.g. web indexing or Google Earth [GooE09].

The project development is subdivided into the design and development of three conceptually separate fields of functionality – a server-side application handling the storage, index and retrieval of digital content, an active-access providing client application (editor), and a passive-access client application (viewer).

The digital content used in our project is rooted in a 4D domain and extended by semantic relations between objects, by multidimensional object attributes and by multimedia content documenting the modeled places from an empathic point of view. The created database offers creating arbitrary and abstract relations through semantic triplets, thus supporting a higher-level knowledge built above the raw city model. The client-server protocol is open and platform-independent which creates opportunities for future extensions and involvement of other domain experts, such as statisticians, sociologists, ecologists and many others.

The editor is partly built upon our previous works on effective presentation of urban data and is being extended to facilitate both technological improvement, e.g. in the form of forming relations and higher-level semantics, and technical improvement, e.g. by introducing vegetation or variable lighting conditions.

The viewer development forks into producing a high-quality viewer oriented on the specialists and technically experienced public and a medium-quality viewer offering less options in both interaction and visualization but being more accessible to the wide audience. Thus, in the end, each of the user groups will be provided with tools to satisfy their needs without being bothered with excessive or overwhelming options or requirements. Each of them uses its own conveying technology, the high-quality viewer is based around our Effective Presenter for Urban Data [Samu08] and uses a GPU-accelerated client-side web object, while the medium-quality viewer uses Adobe FLASH technology which is available to the wider audience for the price of simpler and less detailed visualization.

As the specification of these modules is not open for public yet, we hope to present them in detail in one of our future publications.

We cooperate with EUROSENSE Slovakia, contributing with preprocessed aerial photos in the urban area shown in Figure 2. The detailed project requirements and functional specification take into account recent findings and they will be tested both with the full urban model and respective target groups within the case study Petrzalka.

5 RESULTS

Since the project start in September 2009, we continue to build the geometric model first. Data, tools, and methods from previous projects [Ferk04], [Boro07], [Boro08] are either adopted or under development to meet new requirements. Thinking about MUVIS in terms of cooperative creation and evaluation of possibilities in geometric-semantic domain, neither geometric nor semantic aspect can be reduced in given application area. This is why we require multidimensional attributes or metadata beyond the 3D/4D spatial domain. Current version of Virtual Bratislava model represents a cyber city heavy model, available on DVD. Microsoft® Virtual Earth™ is a geospatial mapping platform for layered data for given location [MSVE08], [WiVE08]. Google Maps is both service and technology [WiGM08], related to the virtual globe of Google Earth [GooE08], [WiGE08] and even extending to the outer space. Both global projects have limited use and precision and they simulate mainly flyover options and exploit satelite and aerial photos of Earth. Our previous project [Ftac07] can be considered as an analogy to Google Earth. The challenging task of online browsing or even editing higher precision urban models is done in Virtual Old Prague [VirP09] or Virtual Berlin [VirB09] by downloading data and/or viewer. MUVIS aims to offer an acceptable online solution. The result of the first experiments – with smaller dataset, part of Petrzalka - is illustrated in Figure 5. The model already includes the virtual vegetation and an inserted urban vision – visualization of one of the many alternatives of the ice hockey stadium for the forthcoming World Hockey Championship in Bratislava 2011.

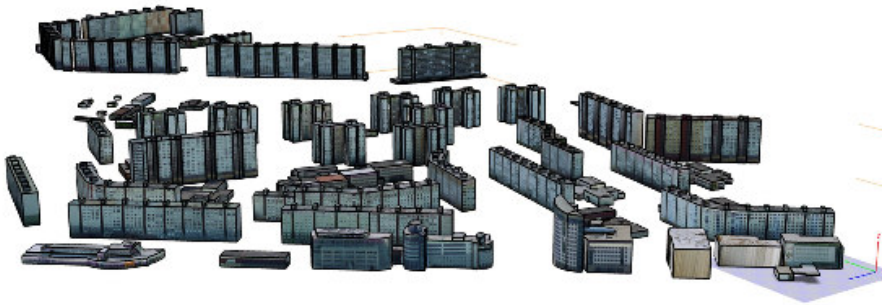

Figure 4: Initial Petrzalka dataset without terrain and vegetation. Data from EUROSENSE company.

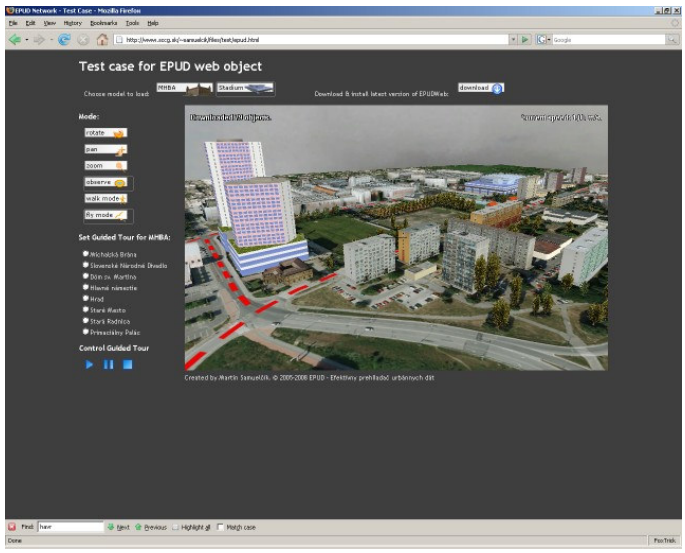

Figure 5: A model of a part of Petržalka in Mozilla Firefox using our EPUDWeb object.

The first piece of the final model and the parameters of the given experiment do not allow for interpretations. The design of the final interface will certainly differ from the prototype examples above. Last, but not least, the inserted urban vision was not included there by a member of the wide target group, but by an expert in the field. This is just the first view of Petrzalka part over internet. Our work is in progress and at the CORP conference we will present a more matured report.

6 CONCLUSION AND FUTURE WORK

MUVIS (Multidimensional Urban Visions) is an three-years applied research project for creating an extensible platform that will support online participatory urban planning and related multidimensional

visualization. MUVIS will support and initiate public discussion and dialogue between the people, the local authorities, and the real estate investors. We use Virtual Petrzalka as a place to demonstrate our efforts in a real-world case study, a place to support creation and visualization of the current state and the future visions. MUVIS offers a state-of-the-art technology solution, transfers the ideas from academy to practice and attempts to influence the future development of our cities in the best was possible.

From the point of view of the widest target group, our intention is to enable people not only in poor Petrzalka to be consciously and interactively participating with their contribution to the future of their own environment. We hope that our model of cooperation, our workflow, and project results might be inspiring within the arising information society.

7 ACKNOWLEDGEMENTS

Project MUVIS - Multidimensional urban visions - is an ongoing project supported from a structural grant scheme OPVaV-2008/4.2/01-SORO; ITMS 26240220009 in Slovak Republic. The authors of this paper would like to express sincere thanks to a project partner EUROSENSE Slovakia for aerial data acquisition and preprocessing. We thank to our colleagues at Comenius University for their support and fruitful discussions.

Instruments for sustainable urban development in Eastern Germany – the example of the "Wächterhäuser" (warden houses) in Leipzig

Kornelia Ehrlich

(Kornelia Ehrlich, Leibniz Institute for Regional Geography, Schongauerstr. 9, 04329 Leipzig, k_ehrlich@ifl-leipzig.de)

1 ABSTRACT

Since the collapse of the GDR, Leipzig, a middle-sized city in Saxony, is characterised by a dualistic process: on the one hand the reconstruction of around 80 per cent of its old dwelling houses. On the other hand the loss of more than 100 000 inhabitants since 1989. Although the number of inhabitants has increased since 2001, Leipzig still had around 38 000 empty dwellings in 2008[1]. Economic and demographic forecasts predict that it would need several decades to reconstruct and use all these empty buildings.

Especially the handling of around 2 500 buildings of the Gründerzeit is an urgent issue for the city. These dwelling houses are often located at central main roads and therefore important for the urban structure. But due to their unattractive location they often remain empty which leads to a constant decay. This has negative consequences for the image and infrastructure of the surrounding neighbourhood and city quarters (Heck and Will 2007 p. 24-25).

One self-governed instrument which was developed against this urban deterioration is the concept of the so called „Wächterhäuser"(warden houses). The principle of this instrument is the preservation of houses through usage.

On the one hand, the "wardens" receive a house for little money, which they can shape following their needs and ideas. On the other hand they only have to pay the running costs and are responsible for keeping the house in good condition and for removing damages. Especially social, cultural, and commercial users, who exercise a certain appeal on the quarter, are potential wardens[2].

The paper asks which type of users can be found, whether this instrument for urban development is a sustainable self-governance strategy for a city like Leipzig. And it asks whether this concept is also fruitful for other contexts.

2 INTRODUCING THE CONTEXT

2.1 Demographic- and Urban Development in Leipzig since 1989

Since the collapse of the GDR, Leipzig is characterised by a deep demographic transformation. The following table gives an overview of the demographic development of Leipzig since 1989 until 2008, in relation to the live birthrate and the number of people moving in and out of Leipzig.

	1989	**1994**	**1999**	**2004**	**2006**	**2008**[3]
Inhabitants	530 010	481 121	489 532	498 491	506 578	515 469
Live birthrate	5 961	2 531	3 582	4 274	4 410	5 096
People moving in	11 390	13 097	21 015	23 306	23 969	25 640
People moving out	27 191	19 102	20 700	21 463	19 030	20 419

Source: Land Statistical Office, Department for Statistics and Elections Leipzig

After a harsh decrease of inhabitants, due to unemployment, suburbanisation, and decreasing birth rates, the number of inhabitants has increased since 2001 and has reached around 515 469 by the end of 2008 (Stadt-Leipzig 2009d p. 3). At the level of urban development, Leipzig faces the problem of a high vacancy rate – in 2008 Leipzig had around 38 000 empty dwellings[4]. Especially the handling of around 2 500 buildings of the Gründerzeit is an urgent issue for the city. These dwelling houses are often located at central main roads and are important for the urban structure. Due to their unattractive location they often remain empty which

[2] See http://www.haushalten.org/de/waechterhaeuser_modell.asp, last visited: 11.12.2009.
[3] In 2009 the number of inhabitants for the city of Leipzig reached 519 300, LVZ article: „Leipzig wächst gegen den Trend", 17.03.2010, p. 21.
[4] LVZ article: „Weniger Wohnungen stehen leer", 18.02.2010, p. 17.

leads to a constant decay. One of the main problems the city faces is the fact that most of these empty Gründerzeit buildings are private property and the city does not have the financial resources to buy all these houses (Heck and Will 2007 p. 27).

Generally speaking Leipzig is marked by two developments:

First, the urban landscape of Leipzig is characterised by parallel shrinking, especially in western and eastern quarters, and growth, especially in the south of Leipzig (Heck 2005 p. 8-9). Especially the shrinking process has implications for almost every field of the city, concerning urban structure, functioning neighbourhoods, or social and cultural offers. The city has identified the problem and adapted several instruments for the revitalisation of empty areas and dwellings. One example are programs like URBAN II or EFRE with different funding focus. The aim of these programs is the development of disadvantaged city quarters through different instruments like urban rebuilding or interim usage (Heck 2005 p. 10).

Second, the predictions for the urban development of Leipzig are marked by a demographic obsolescence of its inhabitants.

Therefore it is necessary to develope further innovative ideas in order to cope with the problems that result from this ongoing demographic and urban transformation process (Heck and Will 2007 p. 24-26).

2.2 Self-governance strategy: HausHalten e.V.

An example for such an innovative idea is the private association HausHalten e.V. Since October 2004 HausHalten e.V. is concerned with the activation of empty (Gründerzeit) dwellings in Leipzig. The association functions as mediator between the owners, the potential wardens (users) of the houses, and the City administration. The latter has a promoting role in this project - the Department for Urban Regeneration provides the start-up financing (HafenCity 2008 p. 44).

An important precondition for the realisation of the warden house concept was the implementation of a regulation in 1999 that allows the temporary public use of empty private properties. Hereby the building law remains legal and HausHalten e.V. receives the usage right for five years. After this period the property owners shall negotiate directly with the wardens about the further usage of their houses (Heck and Will 2007 p. 29).

The strategy of HausHalten e.V. can be put in a simple phrase: preservation through usage. The association searches for suitable wardens who are willing to preserve a house even under difficult conditions (Heck 2005 p. 47). But the association is not only seeking for a simple preservation; it wants to reach a cultural, unconventional, and innovative usage of the houses because it wants to increase the local, national, and international attention, attract new investors and by that revitalise city quarters. The stabilisation of structural disadvantaged city quarters shall be realised through usage (Heck 2005 p. 41-47).

The advantages of the warden house project are amongst others the compatibility with the financial problems of the city and the attractiveness for the owners and wardens of the houses. The owners are responsible to provide functioning electronic and water connections and the restorage of the buildings for usage. Here, public fundings are available. The wardens receive information from HausHalten e.V. and the tools they need for the restoration of the houses. Additionally the wardens pay a membershipfee which is used for the activation of other empty houses. And they sign a contract with the association about their engagement in the restorage and usage of the house. These contracts present a commitment of the wardens and secure the alienability of the concpet into other contexts (HafenCity 2008 p. 44-45).

HausHalten e.V. pursues different goals with its warden house project: It wants to safe cultural monuments (Gründerzeit houses), advise the owners of the houses, find users who are willing to keep the houses in condition, revitalise city quarters through social and cultural offers, retrieve from the contracts between the owners and the wardens, so that both sides can contract directly, promote employment through integration of unemployed in the process of restoration of the houses, and spread their concept in other municipalities with similar problems like Leipzig (Heck, Pantzer et al. 2006 p. 36).

Although HausHalten e.V. is successful - until now they take care of about thirteen warden houses in Leipzig and they have more wardens than houses - the project cannot be continued abundantly due to the difficult financial situation of the municipality and the strict obligations for the signing of the contracts. That is why

self-governance strategies like this have to be strengthened and promoted in this field (Heck and Will 2007 p. 34).

3 THE WARDENS

HausHalten e.V. is looking for wardens that will exert positive effects on the quarter of the warden houses. Therefore especially social and cultural agents are potential wardens, because with their projects and initatives they help to revitalise disadvantaged quarters and integrate the citizens of the quarters (Heck, Pantzer et al. 2006 p. 36). The usage of the houses for living is not intended because then HausHalten e.V. would turn into a competitor on the housing market of Leipzig.

At the moment Leipzig has thirteen warden houses; the (potential) wardens are diverse, among them are artists, entrepreneurs (start-ups), and associations with a social focus (Friemel 2009 p. 98-99). In 2009 HausHalten e.V. had 700 potential wardens. Due to this huge interest, the potential wardens have to present a concept for the usage of a house[5].

Below, three examples of warden houses and their wardens are presented:

[5] http://www.haushalten.org/, last visited: 4th February 2010.

Warden house	Wardens	Profile
Lützner Str. 30 (western quarter)	- project- and audiogallery "A and V"	- a platform for exhibitions; the program is organised by graduates of the Academy of Visual Arts Leipzig and University Hildesheim; they show photographies, videos, drawings, and sculptures
	- two studios for artists	- studio Kathrin von Ow - studio Windisch/Schimkat/Weber
	- copy- and printing service	- first start-up in a warden house
	- warden community	- provides the wardens with information and tools for the restauration
	- cultural platform "Purpur"	- cultural platform and open stage for different theatre events
Kuhturmstr. 4 (western quarter): first released warden house – the wardens have signed directly a contract with the owner)	- KUHTURM	- room for exhibitions with focus on media art
	- studios for students of the Academy of Visual Arts Leipzig	
	- studio Winterhagen/ Schinkel/Kowalski	- three students of the Academy of Visual Arts Leipzig founded this studio
	- social association	- self-initative from migrants from eastern Europe, they offer language courses and cultural events
Eisenbahnstr. 109 (eastern quarter)	- Leipzig office of network operator MAXX on Air	
	- DSP – democracy and social work	- association provides people with food, books, clothes, and household stuff, legal advices; people can use the library, participate in cultural events and advanced training courses
	- gal.lery for digital culture e.V.	- gallery for digital gallery and installations; platform for exhibitions, events from the digital world (blog-lounges, spam-slams), and workshops
	- warden community	- participates in/organises events in the quarter

Source: http://www.haushalten.org/de/realisierte_objekte.asp (last visited: 21th February 2009)

The warden houses are not only seeking for start-ups or entrepreneurs from cultural, creative, or social fields. In the process of the restoration of the warden houses, HausHalten e.V. also integrates long-term unemployed who are living in the quarters in order to intensify the identification with their quarter and give

them the possibility to be active participants in the process of revitalising their neighbourhood (HafenCity 2008 p. 45).

4 OPEN QUESTIONS

The warden house project of HausHalten e.V. presents a self-governed strategy from below and deals with the revitalisation of disadvantaged quarters in Leipzig. The private association took over responsibility for an existing urban and social problem. The city of Leipzig depends on self-governed initatives mainly due to financial problems. At the same time the City administration promotes the project when it comes to the start-up finance.

Still, two questions remain: Is the instrument of the warden houses a sustainable self-governance strategy for a city like Leipzig or is it a convenient way for the City administration to shuffle off responsibility? And is this concept transferable into other municipalities?

4.1 Warden houses – sustainable self-governance strategy?

Like already mentioned above, the municipality Leipzig cannot restore all empty Gründerzeit buildings due to financial shortages. Therefore HausHalten e.V. plays a decisive role for the revitalisation of these buildings and the surrounding quarters. In order to realise their plan the associtation benefits from several structural decisions: in 1999 a regulation was implemented that allows the temporary public usage of unused private properties. Hereby the building law remains legal (Heck and Will 2007 p. 29). Furthermore the wardens sign a contract with the association about their engagement in the restorage of the house. These contracts present a commitment of the wardens and secure the alienability of the concpet into other contexts (HafenCity 2008 p. 44-45). And owners can rely on public funds in order to fulfil their duty to supply water and electronic connections and a basic restauration.

Karsten Gerkens from the Leipzig Department for Urban Regeneration describes the warden house project as a realistic economic solution for social and urban decay and derotation. The increased attractiveness of city quarters by restored Gründerzeit building might, in the long term, attract new investors and bring capital to the city[6].

The warden house idea is under further development: future plans include a program for owner-occupiers. Here, interested individuals form a building owners group and restore together Gründerzeit buildings and use them jointly[7].

All these facts show that the associtation has developed a sustainable strategy in order to cope with present and future problems of urban spaces, in relation to specific developments like the demographic shrinkage, vacancy, and municipalities with less money for social and urban issues. HausHalten e.V. integrates different issues into its project: it is not only concerned with a simple restoration of empty and decayed buildings, with its concept HausHalten e.V. also tries to overcome social and cultural deficits – it integrates long-term unemployed and neighbours of the warden houses, offers graduates and other entrepreneurs cheap space and development opportunities and gives mainly social associtations the chance to improve the coexistence of people living in disadvantaged quarters with high unemployment, and vacancy.

Especially when municipalities and states retreat more from social, cultural, and urban issues, like it is happening in the recent years, self-governed strategies will become even more important. The active participation of private associations and groups is an important instrument to overcome social and cultural divides – the warden house project is a good example for this concern.

4.2 Transferability into other cities?

Several examples show that the idea of the warden houses from Leipzig has become a role model for other cities with similar demographic and urban problems. Warden houses have opened in other Eastern German cities like Görlitz, Dresden, Halle, and Chemnitz; now also Western German municipalities like Bremerhaven and Wuppertal are interested in this idea.

[6] http://www.haushalten.org/de/haushalten_pressearchiv.asp#2007, last visited: 3rd February 2010

[7] http://mephisto976.uni-leipzig.de/sendungen/direkt/beitrag/artikel/waechterhaeuser-ruine-oder-raum-fuer-ideen.html, last visited: 3rd February 2010.

In order to advise other cities, HausHalten e.V. is funded by the Federal Ministry of Transport, Building, and Urban Development. The association advises other municipalities how to find new users for historical buildings in order to preserve these buildings.

5 CONCLUSION

In the middle of 2006, HausHalten e.V. made up a first balance of its project: it revealed that the basic restoration of the Gründerzeit buildings keeps them on a level for further preservation; the warden houses present new knots for identification of the people living in these quarters; networks are builded through the revitalisation of former stores in the warden houses by artistic projects and associtations; by that, new residents move to these quarters (Heck, Pantzer et al. 2006 p. 37).

The financial shortages of the municipalities bring self-governed strategies like the warden house project into the focus of the City administration. HausHalten e.V. works closely together with the municipality in order to realise sustainable urban development in disadvantaged city quarters. Additionaly the association is funded by the Federal Ministry for Education and Research in the frame of the project "Citizens initiate sustainability". HausHalten e.V. is also engaged in cooperations with different educational providers in order to promote local employment (Heck, Pantzer et al. 2006 p. 37).

The associtation hopes that the further development of the warden house idea might lead to more engagement of citizens in their city and their active participation in the shaping of a city image. That would be an alternative to expensive sanitation or, even worse, demolition.

1 ABSTRACT

For disaster risk management and risk-based urban planning, time-dependent knowledge on the spatial distribution of various social groups is of critical importance. However, in a highly dynamic urbanizing world data are mostly outdated, generalized, not area-wide, not reliable or even not existing. This paper explores the potential of interdisciplinary integration of social science and remote sensing to deal with the problem of area-wide and up-to-date information derivation of the spatial distribution of population, and especially the vulnerable groups. The integration of conventional socio-economic data (census and household survey data) with the structural information of the urban landscape extracted from remotely sensed data aims at assessing dynamic exposure of various social groups. The analysis was done for the case study in the tsunami and earthquake prone coastal city of Padang, West Sumatra, Indonesia. The information generated is particularly useful for giving an additional insight for urban planners, how land use and urban development shape the exposure of various social groups to natural hazards.

2 BACKGROUND AND RATIONALE OF THE STUDY

In light of global environmental change, building a safe environment for urban areas should be more emphasized. Two decades ago, an analysis of the world´s 100 most populous cities found that 78% were exposed to one of four major natural hazards-earthquakes, tsunamis, volcanoes, and windstorms (not including flooding)- and 45% faced being struck by more than one. In developing countries alone, 86% face more than one threat (Degg, 1992). For development of effective disaster risk reduction measures, vulnerability assessment is crucial. It should consider exposed, susceptible elements (e.g. population or various social groups) and coping capacities, which determine the expected harm resulting from a given hazardous event (Birkmann, 2006).

An exposure analysis that provides accurate and detailed information about distribution of population and various social groups in relation to the existing hazards is an important initial phase in vulnerability assessment. It serves as a basis for planning disaster risk mitigation, e.g. evacuation planning (short- to medium-term) or exposure reduction by means of land use planning (medium- to long-term). Due to the dynamic in urban activity pattern, spatiotemporal variation of population is a crucial component regarding vulnerability. A time-geography approach to spatial behaviour has long been developed by researchers (Hägerstrand, 1970; Pred, 1981). Presently, it has already been operationalized using various highly developed GIS-tools and methodologies and used in planning, e.g. development of transportation network, access to public services and infrastructures.

Since the 1970s, remote sensing estimation of residential population has been applied more frequently, as an increasing amount of spaceborne satellite data have become available (Elvidge et al. 1997; Lo, 2001; Sutton et al., 1997, Harvey, 2002; Li & Weng 2005; Taubenböck, Roth & Dech, 2007; Liu & Herold 2007; Lo, 1986; Lu et al., 2006; Schneiderbauer & Ehrlich, 2007; Mesev, 2003). The most recent study of Khomaruddin et al. (2008) shows the potential of Census data to derive weights for population distribution day and night by land use type, which is suitable for broadscale analysis (e.g. nation-wide). On the other hand, Taubenböck et al. (2008) presents capabilities of high resolution satellite data (Ikonos) to assess day and night urban population on building level which is suitable for the small-scale and heterogenous urban context. The method used is an object-oriented, hierarchical classification methodology, on very fine resolution. However, the result has not yet indicated the spatial distribution of the vulnerable social groups.

The study presented in this paper attempts to further develop the methodology used by Taubenböck et al. (2008) and Khomaruddin et al. (2008), emphasizing more on the socio-economic characteristics and daily activity pattern of the individuals / households. Analysis of conventional census data and household survey is conducted to build a model of population distribution that is combined with spatial data. In doing so, the identification of vulnerable social groups in various building - land use types is made possible.

3 STUDY AREA AND DATASETS

The study area is the coastal city of Padang, West Sumatra, Indonesia. Padang city with almost one million inhabitants is highly exposed to various natural hazards, especially earthquake and tsunami (Borrero et al., 2006; McCloskey et al., 2010). This city represents coastal urban areas in developing countries, which was initially developed through historical intensive trading activities at the coast during colonial times, and therefore, remains having central activities and densely populated areas at the coastal region. The recent strong earthquake events, of which the most recent one occurred in September 2009 with a magnitude of 7.5M (USGS, 2009), and their potential in generating tsunamis have triggered the city to revise their current urban plan and develop the city towards less-exposed areas, moving away from the coast. As one of the baseline information, it is important to show how the current urban structure has influenced the exposure of the population and various social groups to tsunamis. The required information should encompass the quantity of population and its spatiotemporal dynamic, as well as identification of vulnerable social groups, such as women, elderly and children. Presently, spatial data on population are only available at village level and contains no information on the temporal aspect. Therefore, analysis of ancillary data from remote sensing as well as additional surveys are conducted.

High resolution remotely sensed data from the Ikonos sensor, a Digital Surface Model (DSM) and a Digital Terrain Model (DTM) were used to provide area-wide, up-to-date and accurate information on the urban land cover and its spatial structural pattern in a 3-D city model. Additionally, data derived from field work on urban land use are available (Taubenböck et al., 2009a). The information on daily activity pattern obtained from household survey data 2008 (UNU-EHS Household Survey in Padang, 2008) cover an activity diary of about 800 respondents representing different gender groups, main activities and occupations. Additionally, data from the last population Census (BPS, 2000), and additional statistical data of year 2005 from Padang in Figures (BPS, 2006a), Padang`s Sub-Districts in Figures and Village Potential Survey (BPS, 2006b) are available for calculation of population number by social groups as well as concentration of economic activities and public facilities within the study areas, from which the weights for various land use types are derived.

4 CONCEPTUAL FRAMEWORK & METHODOLOGY

An analysis framework was developed to enable estimation of spatial distribution of exposed social groups and was applied for the case study. The starting point of the analysis is the assumption that exposure of social groups to tsunamis varies and influenced by the urban land use. Based on this assumption, the parameters were defined and analysed:

- classification of social groups with regard to vulnerability to tsunamis
- main activities that compose daily activity pattern & particular time of the day to show the temporal dynamic
- linkage between building-land use and daily activity

4.1 Vulnerable Social Groups and Daily Activity Pattern

With regard to tsunamis, the following social groups have been revealed as more vulnerable: women, elderly and children (See e.g. Birkmann et al., 2007). This particularly relate to lower physical capability of these groups to evacuate themselves during an emergency or tsunami events, i.e. low running (evacuation) velocity and stamina. It is important to analyse the population distribution disaggregated for these social groups. Aside from demographic characteristics, there are other parameters to be considered in assessing vulnerability, e.g. households with lower income and marginalized social groups are most likely to have lower access to disaster preparedness interventions such as early warning and training activities, as well as to face more difficulties during recovery process after a disaster event. In this case study, however, the linkage

between such parameters with the dynamic spatial distribution have not been explored sufficiently, thus, not integrated yet.

The time geographic model of society potrays individuals and households as following a series of daily paths through time and across space, with their movement at such settings as home, office, school, shops, and sites of discretionary activities such as the church or community center (Pred, 1981). Time-budget studies, in which respondents are asked to keep an activity diary specifying the duration and location of activities, are permitting to emerge a fine-grained picture of the temporal and spatial use of the city (Anderson 1971, Chapin 1974).

In this study, the daily activity was derived from an activity diary from the household survey. It was summarized in three main categories: working activities (occupation in built areas: service, trade, industry), education (school and higher eduction), and other activities (care and social activities). The daily activity pattern was found to be different particularly between women and men, with main activity of working and non-working (Figure 1).

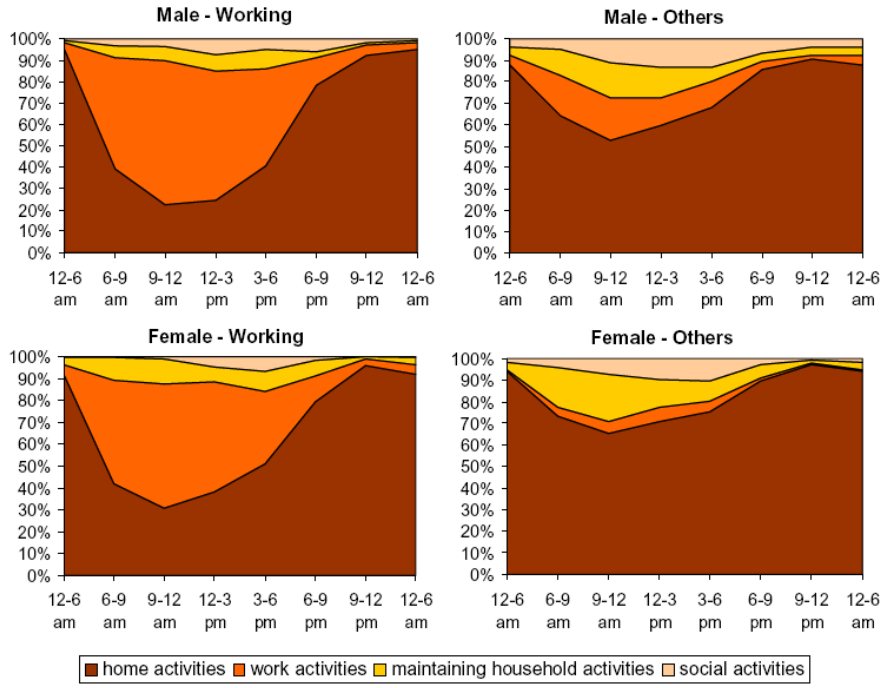

Fig. 1: Daily Activity Pattern of Various Social Groups

For the exposure analysis, three different times over the course of a day were selected to show the temporal dynamic of the daily activities: 9-12 am (morning), 3-6 pm (afternoon), and 12-6 (night).

4.2 Urban Morphology and Daily Activity

Urban morphological analysis seeks to identify distinctive regions in the city according to the functions of tangible land use types and to some extent show the social urban segregation. For the detailed extraction of the small-scale and heterogeneous urban morphology, Ikonos imagery with 4 spectral bands (blue, green, red, nir) and a geometric quality of 1 meter were used. The Digital Surface Model (DSM) and the Digital Terrain Model (DTM) are also available. Additionally, data derived from field work on urban land use were surveyed. The combination of the various data sets provides information on the physical urban morphology of the city, building use and available space for living and working (Figure 2).

Regionalisation is performed to classify areas that contain homogeneous urban morphology parameters (See Taubenböck et al., 2009b). Areas with similar built-up density, building sizes, building heights and building usage are combined citywide as homogeneous sectors (Figure 3). Particularly areas with low built-up density, big building sizes, and high height are mostly representing public buildings.

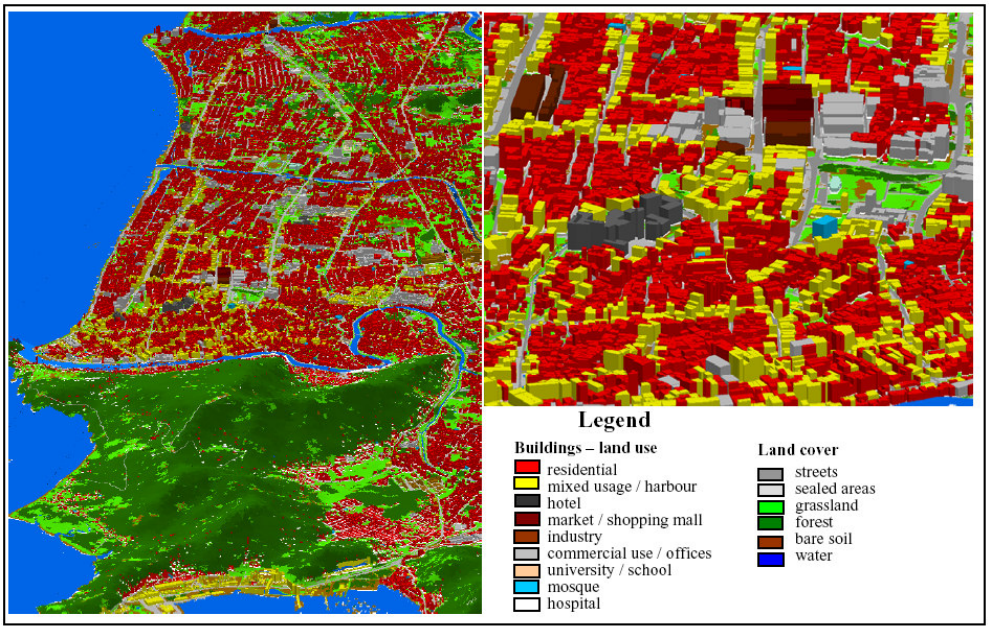

Fig. 2: Building - Land Use of the Study Area in Padang City

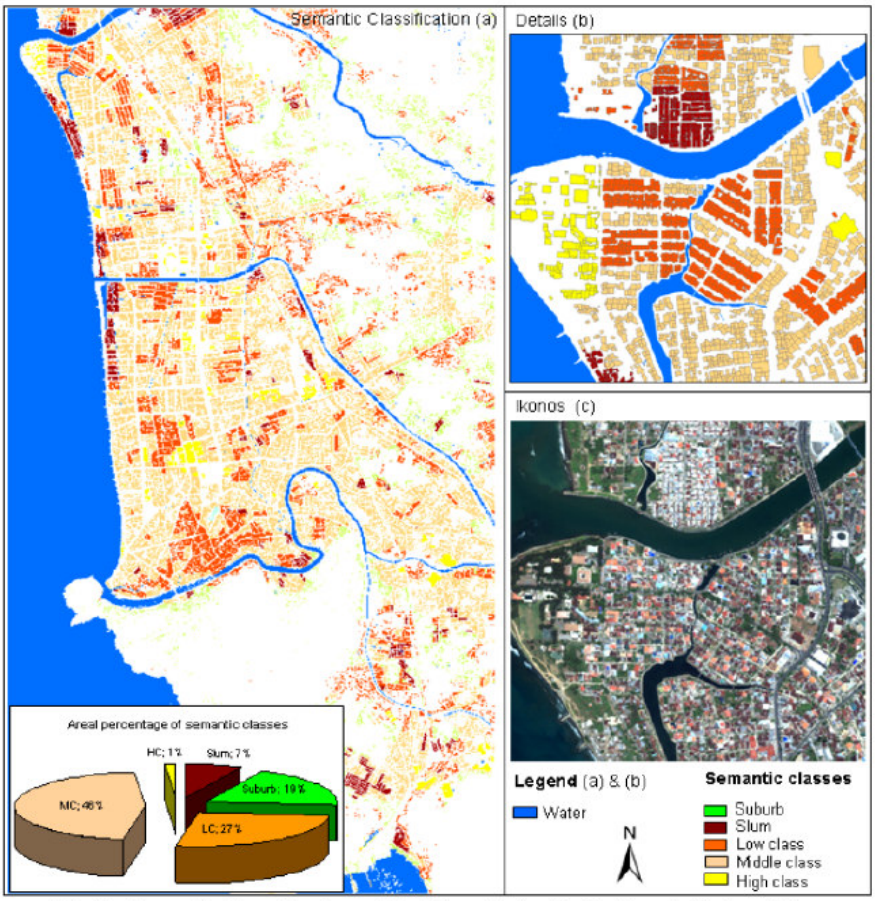

Fig. 3: Semantic Classification of Buildings in the Study Area in Padang City

The correlation between the static elements of physical urban structures with the socio-economic parameters of the people was tested. The findings proved that socio-economic characteristics like household income level and price of housing correlate to some extent with physical urban patterns and thus enable extrapolation on the complete urban landscape (See Taubenböck et al, 2009b). The classification of the physical urban structures are particularly used for the residential buildings. For the working activities, the building-land use is summarized in several main categories which match the activities of the population from the Population Census and Household survey data, namely office, commercial, and industrial buildings.

4.3 Development of weighting

Similar with the methodology used by Khomaruddin et al. (2008), weights are derived from the available socio-economic data to calculate population distribution in the study area, but putting more emphasize on the social groups and their daily activity pattern. The important parameters are the main activity, occupation of the social groups and their mobility (to what extent the individuals travel to conduct their daily activities). For the purpose of our analysis, mobility is defined as whether or not the daily activities are performed at home/neighbourhood (in the residential buildings) or in public facilities and buildings where economic and business activities are concentrated in the city. The overall analysis framework is presented in a simplified manner in the following figure (Figure 4), showing the example of the activities of female population.

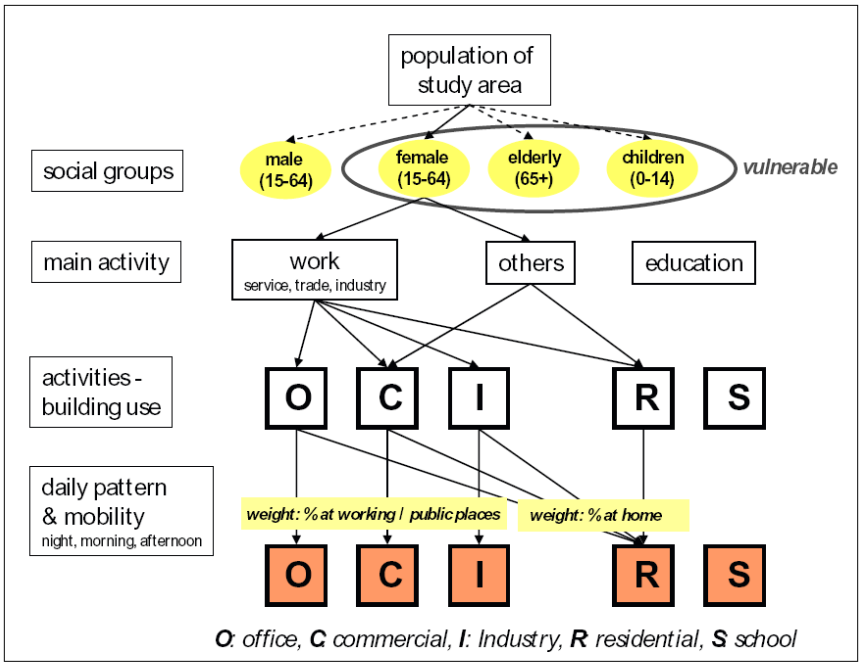

Fig. 4: Analyis Framework

During the analysis, some additional assumptions for the weights had to be made due to inexistence of information e.g. activities in the mosques and in public facilities. However, this involved relatively small part of the total population and did not change the results significantly.

5 RESULTS

Basically we observe and quantify high concentration of people in the urban center during morning and afternoon, while at nighttime the people are more equally distributed. During daytime we measure higher exposure of the total population due to the fact that more people linger in the urban core near the coastline. The analysis results of population distribution show that there is an immense spatial shift in population distribution for non residential areas between day- and nighttime, and slightly less during the afternoon time (Figure 5). The non-residential areas are mostly located in the city center and along the main roads, where the economic and business activities are concentrated. Thus, the spatial pattern of vulnerability transforms significantly over the course of a day and e. g. with immense impact on the situation for evacuation in case of tsunami events (Lämmel et al., 2008).

Disaggregated analysis on vulnerable social groups show in general similar pattern with the total population, nevertheless different weighting in activities of various social groups show noticable variation. Overall, the activities outside house (residential buildings) of the vulnerable groups is lower due to the fact that the proportion of working female (29.4%) and working elderly population (40.3%) is much less than the working male population (63.9%). Additionally, the household survey showed that the proportion of working activities of the working vulnerable population that are conducted at home is higher compared to of the male population. This variation has implication on the population shift during the day of vulnerable and male population, as well as difficulties that these social groups would face in evacuation during emergency events. More vulnerable population stay in residential areas during the morning and afternoon time, while increasing male population are concentrated in the non-residential areas during the day. In terms of evacuation, it

indicates difficulties lower access of the vulnerable population to the main roads (evacuation routes) in the dense residential areas with mostly narrow street networks, while the concentrated population in the city center and along the main roads might already initiate traffic jam Moreover, some punctual variations in different building – land use types are also visible for the vulnerable groups as can be seen in Figure 6 below. In this example, the low proportion of vulnerable groups working in the industrial sector (20.5%) show variation in changes during the day, compared to changes in university, where participation of vulnerable groups is higher (55.1%). Such disaggregated information of vulnerable groups is also significant in e.g. hospital buildings, that consist of almost 90% vulnerable people.

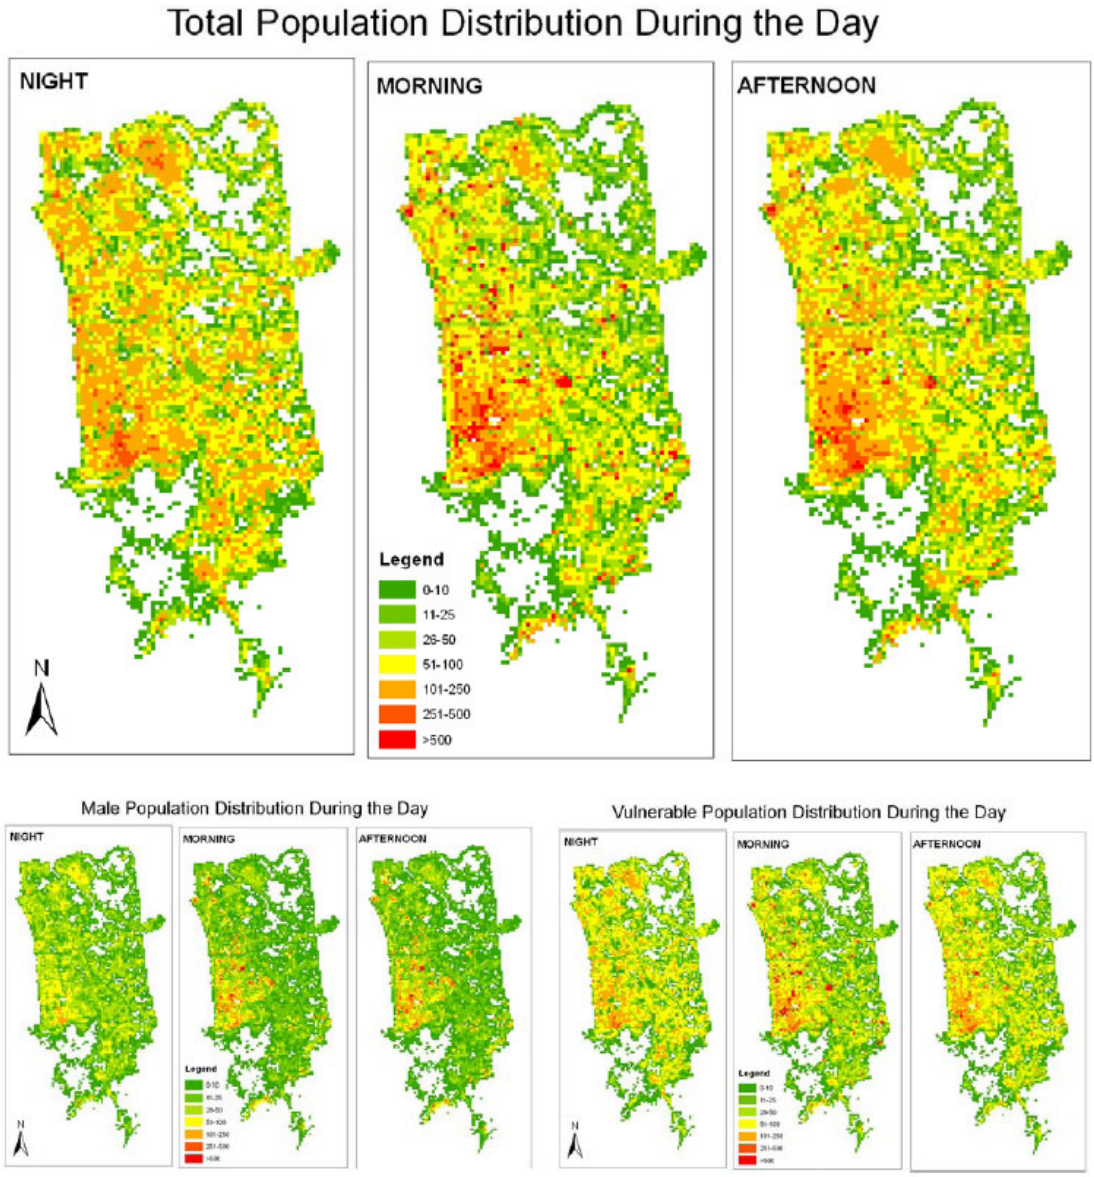

Fig. 5: Distribution of Population by Daytime (Visualization of Summary in Grids 100mx100m)

To check the accuracy of the basis population (night population in the residential areas) of our calculation, the results were compared with the available population data of year 2005 in the villages, where the study area is located (BPS, 2006b). The total population in the study area coverage within the selected villages is summed up to 428,452, including 275,845 vulnerable population, while the total population in the residential buildings based on our calculation is 387,450, of which 257,682 are vulnerable population. The comparison shows that a difference of about 10%, nevertheless, our calculation generated the same magnitude of population as well as vulnerable population. Comparison was also done using single household data from the household survey, showing that the proportion of vulnerable population at building level is on average similar, but vary at the building level with the standard deviation of 20%. This also conforms to variations at the household level from the analysis of Census Population Data (BPS, 2000). Accuracy analysis of the

population distribution in the morning and afternoon time at the building level was not possible, since there is no validation data available.

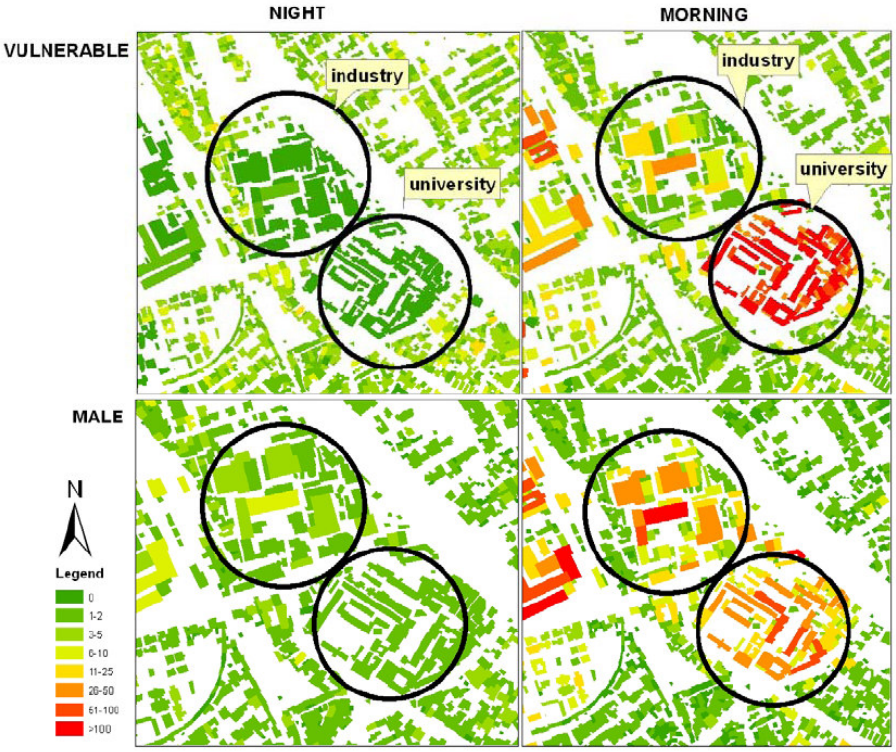

Fig. 6: Variation in Distribution Different Building-Land Use by Daytime and Social Groups

6 CONCLUSION AND OUTLOOK

The study presented above shows that detailed analysis on population distribution for high resolution exposure analysis is made possible through the combination of remote sensing analysis and conventional socio-economic data of census and household surveys. In spite of high level of details of the information, the analysis method can be easily understood and implemented for continuous updating by the local risk managers and urban planners, in contrast to complex modelling analysis. It provides an overview of "who", "when", "where", as a basis information for risk managers and urban planners to develop effective mitigation strategies such as evacuation planning. Moreover, the analysis results can easily be linked and overlayed with data on tsunami as well as other hazards to assess exposure. For longer-term urban development planning, it would also be interesting to develop a set of scenarios for the analysis, e.g. how the population distribution would change if urban activities would be intensified in areas away from the coast. In case more comprehensive and detailed data on mobility or transportation pattern would be available, such analysis can be further developed and include more complexity. However, this also implies assessment on how much added-value it would bring and its applicability.

1 ABSTRACT

Im Rahmen des Deutschland – Online E-Government Standardisierungsvorhabens XPlanung (Benner, Krause 2009) werden ein semantisches Datenmodell und ein objektorientiertes Datenaustauschformat XPlanGML für raumbezogene Planwerke (Bauleitpläne, Raumordnungspläne, Landschaftspläne) erarbeitet. Die Zielrichtung des Projektes XPlanung lag zu Beginn des Vorhabens zunächst auf der Etablierung eines verlustfreien Datenaustauschs von Planwerken des Baugesetzbuches (BBauG: 1960 – 1987 / BauGB seit 1987) wie dem Flächennutzungsplan (FPlan) oder dem Bebauungsplan (BPlan) zwischen unterschiedlichen CAD / GIS Programmen über Verwaltungs- und Akteursgrenzen hinweg. Im Laufe der Modellierung und eingehender Analyse bestehender Planwerke der Bauleitplanung hat sich herausgestellt, dass der Fokus auf FPlan und BPlan zu eng gesetzt war. In den Flächennutzungsplänen der Stadtstaaten wie der Freien und Hansestadt Hamburg (FHH) werden ebenso Festlegungen der Raumordnung getroffen, die Plan-Art „regionaler Flächennutzungsplan“ ermöglicht es, Darstellungen der Flächennutzungsplanung und der Festlegungen der Raumordnung in einem gemeinsamen Planwerk zu visualisieren. In Bebauungsplänen finden sich Huckepackfest-setzungen aus der Landschaftsplanung.

Auf Grundlage dieser Erkenntnisse wurden Kernmodelle der Raumordnung und der Landschaftsplanung im Objektmodell XPlanung modelliert. Diese Modelle geben jedoch „nur“ die gesetzlichen Möglichkeiten der aktuellen Gesetzgebung wieder. In der FHH existieren sehr viele Planwerke der Bauleitplanung, die auf alten, nicht mehr rechtsgültigen Gesetzeswerken basieren, aber immer noch ihre Gültigkeit besitzen. Um durchgängige E-Government Lösungen in der Bau- und Planungsverwaltung (z.B. elektronisch gestützte Baugenehmigungsverfahren) etablieren zu können, ist es notwendig, das gesamte gültige Planungsrecht digital abbilden zu können. Von daher besteht die Notwendigkeit, neben aktuellen Bauleitplänen auf Basis des BauGB ebenso die Altpläne in dem Objektmodell XPlanGML abbilden zu können. Damit ergibt sich die Notwendigkeit, dies Objektmodell länderspezifisch zu erweitern.

Ziel des Beitrags ist es, nach einer kurzen Einführung in den Entwicklungsstand des Austauschformats XPlanGML (Kap. 2) und einer Analyse des aktuell in Hamburg gültigen Planungsrechts (Kap. 3) verschiedene technischen Möglichkeiten zur Erweiterung des Objektmodells XPlanung zu erörtern, durch die Interoperabilität bei Austausch digitaler Planwerke nicht gefährdet wird (Kap. 4). Dabei wird u.a. diskutiert, in wie weit sich der Application Domain Extension (ADE) Erweiterungsmechanismus im Objektmodell CityGML auf das Objektmodell XPlanGML übertragen lässt. Als Grundlage der Analyse dient das vorhandene Digitale Informationssystem Planrecht (DIP), in dem alle in der FHH gültigen Bebauungspläne – derzeit in einem proprietären Datenformat und inhaltlich nicht vollständig - erfasst sind. Ein Vorschlag zur Erweiterung des XPlanGML Datenmodells wird im Kap. 5 formuliert.

2 EINLEITUNG

Im Rahmen des Deutschland – Online E-Government Standardisierungsvorhabens XPlanung werden seit dem Jahr 2004 ein semantisches Datenmodell und ein objektorientiertes Datenaustauschformat XPlanGML für raumbezogene Planwerke (Bauleitpläne, Raumordnungspläne, Landschaftspläne) erarbeitet. Für die Ableitung des XPlanGML Modells (Krause, Benner 2006) wurden die Regelungen des BauGB, der BauNVO, der PlanzV sowie des ROG und des BNatSchG analysiert und umgesetzt. Alle nach diesen Bestimmungen möglichen Darstellungen, Festsetzungen, Kennzeichnungen, Hinweise und nachrichtliche Übernahmen der vorbereitenden und verbindlichen Bauleitplanung werden im Objektmodell als Klassen mit zugeordneten Attributen abgebildet. XPlanung ermöglicht bei Aufstellung oder Änderung von Plänen einen einfachen und verlustfreien Datenaustausch zwischen den verschiedenen Verwaltungsebenen und den unterschiedlichen öffentlichen und privaten Planungsakteuren. Dies erhöht Schnelligkeit und Sicherheit des

Planungsprozesses und senkt langfris-tig die Softwarekosten. Ein standardisiertes Datenformat ermöglicht weiterhin die einfache und verlustfreie Übernahme der Pläne in Fachinformationssysteme (z.B. Raumordnungskataster, Umweltinformationssysteme).

Im Zuge der Einführung von E-Government Verfahren werden immer mehr Dienstleistungen der Verwaltung auf elektronischem Wege, mit Unterstützung durch das Internet, angeboten. Durch die neue EU-Dienstleistungsrichtlinie wird sich dieser Trend in den nächsten Jahren noch erheblich verstärken. Im Bereich der kommunalen Bauleitplanung sowie in der Raumordnung sind E-Government Lösungen nur auf Basis eines standardisierten, semantischen Datenmodells von Bauleitplänen sinnvoll einsetzbar. Einheitlich strukturierte digitale Bauleitpläne bzw. Planwerke der Raumordnung erleichtern im Rahmen des Aufbaus von Geodateninfrastrukturen die Bereitstellung elektronischer Beteiligungsplattformen für die Öffentlichkeit, Behörden und Träger öffentlicher Belange. Weiterhin ermöglichen einheitlich strukturierte Bauleitpläne die Etablierung unterschiedlicher Recherche-Dienste über die Inhalte von Bauleitplänen und deren anwendungsspezifische Visualisie-rung.

Um weiterreichende durchgängige E-Government Lösungen in der Bau- und Planungsverwaltung (z.B. elektronisch gestützte Baugenehmigungsverfahren) etablieren zu können, ist es notwendig, das gesamte gültige kommunale Planungsrecht digital abbilden zu können. Von daher besteht die Notwendigkeit, neben aktuellen Bebauungsplänen ebenso die sonstigen Planwerke des besonderen Städtebaurechtes auf Basis des BauGB sowie Altpläne, die nicht nach den Regelungen des BauGB erstellt wurden, im Objektmodell XPlanung abbilden zu können. Da bislang das Objektmodell von XPlanung auf die Abbildung der Bauleitpläne gemäß BauGB beschränkt ist, ergibt sich die Notwendigkeit, das Objektmodell zu erweitern.

Das Objektmodell XPlanGML 4.0 wurde deshalb um die Möglichkeit erweitert, Planwerke des besonderen Städtebaurechtes abzubilden. Dazu gehören gemäß BauGB Planwerke, die städtebauliche Sanierungsmaßnahmen (§§ 136 ff. BauGB), städtebauliche Entwicklungsgebiete (§§ 165 ff. BauGB), Stadtumbaumaßnahmen (§§ 171a-d BauGB), Maßnahmen der sozialen Stadt (§ 171e BauGB) sowie private Initiativen zur Stadtentwicklung (§171f BauGB) beschreiben. In Bauleitplänen werden eine Vielzahl nach anderen gesetzlichen Vorschriften getroffene Festsetzungen in Flächennutzungsplänen (§ 5 Abs. 4 BauGB) und Bebauungsplänen (§ 9 Abs. 6 BauGB) nachrichtlich übernommen. Die Bundesländer können ferner durch Rechtsvorschriften bestimmen, dass auf Landesrecht beruhende Regelungen in den Bebauungsplan als Festsetzungen aufgenommen (§ 9 Abs. 4 BauGB). Bislang wurde versucht, diese Vielzahl von möglichen Festsetzungen auf Basis andere gesetzlichen Vorschriften (in der Regel Fachplanungsrecht) in den Fachschemata Bebauungsplanung und Flä-chennutzungsplanung des Objektmodells XPlanung abzubilden. Mit diesem Vorgehen wurde der ursprüngliche Ansatz, die Regelungen des BauGB, der BauNVO, der PlanzV im Objektmodell XPlanung abbilden zu können, stark ausgeweitet. Dieses Vorgehen führte zu einer Vielzahl von Problemen. Zum einen ist es nicht immer gewährleitet, dass der Sachverstand hinsichtlich der Modellierung eines Fachplanungsthemas in den Arbeitsgruppen ausreichend besetzt ist. Zum anderen ergeben sich hinsichtlich einer vollständigen Implementierung des Standards XPlanung für Softwarefirmen Probleme, die auf die Bauleitplanung spezialisiert sind, da diese ebenso die Objektklassen, die Fachplanungsrecht abbilden, in ihren Softwareprodukten implementieren müssten. Das Objektmodell XPlanung XPlanGML 4.0 beschränkt sich in den Fachschemata Bebauungsplanung und Flächennutzungsplanung wieder auf die Abbildung der Regelungen des BauGB, der BauNVO, der PlanzV. Nachrichtliche Übernahmen, Festsetzungen des besonderen Städtebaurechtes sowie weitere Schutzgebiete werden in einem eigenen Fachschema zusammengefasst. Bei Bedarf können diese Modellierungen auch gegen Modellierungen aus der Community des jeweiligen Fachplanungsrechts ersetzt werden.

Mit diesen beschriebenen Konzepten können zwar das aktuelle Planungsrecht nach BauGB sowie die Inhalte von Bauleitplänen inkl. der Abbildung von Festsetzungen des Fachplanungsrechts abgebildet werden. Der Anspruch, das gesamte gültige kommunale Planungsrecht zur Unterstützung von E-Government Anwendungen digital gemäß einem einheitlichen Objektmodell abzubilden zu können, kann noch nicht vollständig erfüllt werden. In vielen deutschen Kommunen gibt es Gebiete (z.B. Berlin, Hamburg, Stuttgart), die auf Basis heute nicht mehr gültigen Planungsrechts beplant worden sind. In diesen Bereichen gilt das historische Planrecht faktisch weiter. Um das in diesen Bereichen gültige Planungsrecht als Basis für E-Government Anwendungen abbilden zu können, muss das Datenmodell XPlanGML individuell erweitert werden können. Da dieses historische Planungsrecht in der Regel nur Gültigkeit für bestimmte Länder (z. B. Gesetz über den Aufbau der Hansestadt Hamburg von 1950) oder Kommunen hatte, ist eine Erweiterung des

XPlanGML-Kerns nicht sinnvoll. Stattdessen müssten auf Ebene einzelner Länder oder Kommunen spezifische Erweiterungen definiert werden. Dafür gibt es verschiedene Möglichkeiten und technische Konzepte, die jeweils Vor- und Nachteile haben.

Ziel des Beitrags ist es, diese Konzepte am konkreten Beispiel der Freien und Hansestadt Hamburg aufzuzeigen und zu vergleichen. Dazu werden, nach einem Exkurs in die historische Entwicklung des Hamburger Planungsrechts, verschiedene Erweiterungsmöglichkeiten innerhalb und außerhalb des Standards XPlanGML beschrieben und in ihren Vor- und Nachteilen verglichen. Am besten geeignet erscheint die Definition spezifischer Codelisten in Verbindung mit einer Adaption des Application Domain Extension (ADE) Mechanismus, der im Rahmen des OGC-Standards CityGML (OGC 2008) erstmals beschrieben wurde, Eine mögliche XPlanGML ADE für das historische Hamburger Planungsrecht wird abschließend in diesem Beitrag skizziert.

3 DAS HAMBURGER PLANRECHT NACH 1945

Ab 1950 begannen auf Grundlage des Aufbauplans von 1950 die städtebaulichen Planungen für einen Neuaufbau der FHH mit dem Ziel, für alle Flächen der Stadt verbindliches Planrecht zu schaffen. Die Umsetzung erfolge in erster Linie über die Baustufenpläne. Gesetzesgrundlage für die Baustufenpläne war die Baupolizeiverordnung für die Hansestadt Hamburg (BPVO) vom 8. Juni 1938, die nach der Etablierung von „Groß-Hamburg“ am 1. April 1938 das zersplitterte und veraltete Planrecht vereinheitlichen sollte. Baustufenpläne wurden für größere Teilbereiche wie z.B. Ortsteile im Maßstab 1:5.000 aufgestellt. Inhalte waren die zulässigen Nutzungsarten entsprechend § 11 BPVO (Kleinsiedlungsgebiet, Wohngebiet, Mischgebiet, Geschäftsgebiet, Industriegebiet), die Geschosszahl von Gebäuden sowie die Abgrenzung der Baugebiete von den Außengebieten und die Bauweise. Der allgemeine Rahmen für die bauliche Nutzung der Stadtgebiete wurde durch die Baustufenpläne gegeben. Die endgültige Festsetzung der baulichen Nutzbarkeit von Grundstücken sowie Straßen- und Baulinien erfolgte anhand der Teilbebauungs- und Durchführungspläne. Insgesamt wurde Hamburg mit 62 Baustufenplänen fast vollständig überplant.

In der Zeit des Aufbaus ab 1950 bedurfte die städtebauliche Planungsarbeit einer gesetzlichen Handhabe vor allem für die Verkehrsplanung in Wiederaufbaugebieten, um nicht durch andere Bauvorhaben verhindert zu werden. Daher wurden private Flächen für öffentliche Zwecke mittels Teilbebauungsplänen nach dem Bebauungsplangesetz (BPlanG) vom 31. Oktober 1923 gesichert. Dies umfasst die Flächen für den Straßenverkehr, den Gemeinbedarf und Grünflächen. Wichtigstes Kriterium war dabei das im Vergleich zum Verfahren für Durchführungspläne kurze Verfahren zur Aufstellung von Teilbebauungsplänen. Nach § 3 Abs. 1 BPlanG von 1923 gelten die Pläne über einzelne Straßen- und Baulinien als Teilpläne. Die rechtliche Grundlage zur Feststellung eines Teilbebauungsplans stellten die §§ 2 (Beschränkungen der Grundstücke) und 4 (Feststellung des Bebauungsplan) des BPlanG von 1923 dar.

Aufgabe der Durchführungspläne nach dem Aufbaugesetz war der Wiederaufbau von Teilgebieten in Hamburg. Rechtliche Grundlage für die Durchführungspläne waren die §§ 10 bis 14 des AufbauG vom 11. April 1949. Da die zum Teil sehr detaillierten Festsetzungen in den Durchführungsplänen nicht immer vollständig zum Ausdruck gebracht werden konnten, wurde diese regelmäßig durch die weiterhin geltenden Bestimmungen der BPVO von 1938 ergänzt. Die Durchführungspläne wurden für einzelne oder mehrere Baublöcke erstellt und beinhalteten eine detaillierte Darstellung als Baustufenpläne. In der Regel wurden diese Pläne in einem Maßstab von 1:1000 erstellt und umfassten daher nur kleinere Gebiete wie z.B. einen Baublock. Inhalt der Pläne waren alle Festsetzungen, die für die Bebauung der Grundstücke nach Fläche und Höhe notwendig waren. Weitere Inhalte der Pläne waren die Aufteilung der Gebiete in Flächen öffentlicher und privater Nutzung, die Verkehrseinrichtungen, die Versorgungsleitungen, die Mindestgröße sowie die Nutzungsart und der Nutzungsgrad des Grundstücks.

Mit dem Inkrafttreten des BBauG im Jahre 1960 verloren das BPlanG von 1923, die Baupolizeiverordnung von 1938 sowie das AufbauG von 1949 seine Rechtskraft, dennoch gelten die Festsetzungen der Altpläne entsprechend § 173 Abs. 3 Satz 1 BBauG von 1960 fort.

4 ERWEITERUNGSMÖGLICHKEITEN DES STANDARDS XPLANGML

Die im Kap. 3 durchgeführte Analyse des historischen, aber dennoch in vielen Gebieten der Stadt weiterhin gültigen Hambuger Planungsrechts hat deutlich gemacht, dass eine vollständige Überführung der Inhalte des DIP in das XPlanGML-Format nicht möglich ist. Da die zusätzlichen, durch das XPlanGML-Datenmodell

nicht abgedeckten Planinhalte sehr spezifisch für die FHH sind und in dieser Form wohl nirgendwo anders in Deutschland auftreten ist es nicht sinnvoll, sie im bundesweit gültigen Standard zu berücksichtigen. Es muss vielmehr eine technische Möglichkeit geschaffen werden, den Standard für die Abbildung derartiger kommunal- oder landesspezifischer Inhalte flexibel erweitern zu können. Dabei sollte die Erweiterung konsistent mit dem Basis-Datenmodell sein und ihre Auswirkungen auf den interoperablen Austausch digitaler Planinformationen minimiert werden.

4.1 Intrinsische Erweiterungsmöglichkeiten des XPlanGML Standards

Dass XPlanGML mit seinen spezifischen, auf ganz bestimmte Inhalte der gesetzlichen Rahmenbedingungen bezogenen Klassen und Attributen nicht jeden existierenden oder gesetzlich zulässigen Plan wiedergeben kann war den Entwicklern des Datenmodells von Anfang an klar (Krause, Benner 2006). Deshalb wurden bereits innerhalb des Standards Möglichkeiten zur Öffnung des Datenmodells definiert. So kann

- der diskreten Wertebereich vieler zur Klassifikation genutzter Attribute durch sog. Codelisten kontrolliert erweitert werden;
- jede Klasse um zusätzliche generische Attribute mit einfachem Datentyp (Text, Ganzzahl, Dezimalzahl, Datum, URL) ergänzt werden;
- ein durch den Standard semantisch nicht abgebildeter Planinhalt mit punkt-, linien- oder flächenhaftem Raumbezug durch eine generische Objektklasse erfasst werden.

Attribute mit diskretem Wertebereich spielen in einem semantischen Datenmodell wie XPlanGML eine wichtige Rolle. Die zulässigen Werte dieser Enumerations-Attribute („Schlüsselnummern“) sind über das XML-Schema des Standards definiert, und den Schlüsselnummern werden über externe Wörterbücher auch für den Anwender verständliche Bedeutungen zugeordnet. Die korrekte Verwendung der Schlüsselnummern kann deshalb in einem XPlanGML Instanzdokument softwaregestützt überprüft werden. Damit können Enumerations-Attribute für spezifische Klassifikationen (z.B. „Art der baulichen Nutzung“ oder „Zweckbestimmung einer Gemeinbedarfsfläche“) benutzt werden. Eine automatische Auswertung und Interpretation von Schlüsselnummern, z.B. zur Flächenbilanzierung oder graphischen Darstellung des Plans ist möglich.

Die explizite Festlegung der zulässigen Werte eines Enumerations-Attributs durch das XML-Schema hat aber auch Nachteile, da sie die möglichen semantischen Bedeutungen dieses Attributs abschlie-ßend festlegt. So kennt der Standard XPlanGML in der Version 4.0 insgesamt 10 „allgemeine Zweckbestimmungen“ einer Gemeinbedarfsfläche (z.B. „Öffentliche Verwaltung“ oder „Soziale Zwecke“), die mit 32 „besonderen Zweckbestimmungen“ (wie „kommunale Einrichtung“ oder „Einrichtung für Kinder“) spezialisiert werden können. Insbesondere auf der Ebene der speziellen Zweckbestimmungen können aber nicht alle Begriffe berücksichtigt werden, die eventuell in einem Plan vorkommen können und bei der Plandarstellung durch spezielle Symbole wiedergeben werden sollen. In diesem und vielen anderen Fällen gibt es deshalb ein Attribut „detaillierte Zweckbestimmung“, dessen Wertebereich außerhalb des Standards durch eine Codeliste frei definiert werden kann.

Mit Codelisten wird aber nur der Wertebereich schon vorhandener Attribute erweitert, es können keine zusätzlichen Attribute definiert werden. Dies ist aber notwendig, wenn für eine im Standard definierte Klasse zusätzliche Informationen wie z.B. neue Maßzahlen, Datumsangaben oder Texte erfasst werden müssen. Für diesen Zweck definiert XPlanGML generische Attribute, mit denen jede vorhandene Klasse erweitert werden kann. Bei der praktischen Anwendung gibt es aber eine Reihe von Einschränkungen:

- Die semantische Bedeutung eines generischen Attributs ist nur durch den Attributnamen definiert. Da dieser nur ein freier Text ist kann die korrekte Verwendung nicht softwaregestützt überprüft werden.
- Es können keine zusätzlichen Enumerations- oder Codelisten-Attribute definiert werden.
- Es können nur Attribute mit einfachen Datentypen definiert werden, aber z.B. keine Attribute mit (physikalischen) Maßeinheiten.

Die dritte Möglichkeit zur Erweiterung des XPlanGML-Standards sind generische Objekte. Für jede in Standard berücksichtigte Plan-Art (BPlan, FPlan, ..) gibt es eine entsprechende Klasse für generische

Objekte. Sie kann verwendet werden, wenn keine vorhandene Klasse mit explizit festgelegter semantischer Bedeutung zur Abbildung eines bestimmten Planinhalts in Frage kommt. Jede generische Objektklasse hat ein Attribut „zweckbestimmung“, dessen Wertebereich durch eine Codeliste definiert wird. Damit können generische Objekte auch zur Wiedergabe unterschiedlicher Planinhalte klassifiziert werden. Wenn neben der reinen Klassifikation noch eine zusätzliche Attributierung notwendig ist kann dies über die schon erwähnten generischen Attribute - mit allen beschriebenen Einschränkungen - realisiert werden.

4.2 Erweiterung durch Spezialisierung von XPlanGML-Klassen

Der zentrale Schwachpunkt der innerhalb des Standards XPlanGML vorgesehenen Erweiterungsmöglichkeiten ist, dass keine zusätzlichen komplexen Attribute definiert werden, deren Syntax durch ein XML-Schema definiert ist. Dies ist aber zur objektorientierten Modellierung komplexer Sachverhalte unverzichtbar.

Bei der Erweiterung der auf bundesweit gültigen Rahmengesetzten beruhenden „Kernmodelle“ der Regional- und Landschaftsplanung ist man deshalb anders vorgegangen (Benner et al. 2008). Für die Entwicklung der landesspezifischen Datenmodelle wurden die Klassen des jeweiligen Kernmodells mit dem objektorientierten Mechanismus der Vererbung bzw. Spezialisierung erweitert. Diese Erweiterung wird durch ein eigenes UML-Diagramm und daraus abgeleitetes XML-Schema definiert, so dass die syntaktische Korrektheit von Instanzen des erweiterten Datenmodells automatisch geprüft werden kann.

Diese Erweiterungsmethode durch objektorientierte Spezialisierung kann im Prinzip auch außerhalb des Standards zur Modellierung landesspezifischer Inhalte von Bauleitplänen oder zur Abbildung historischem Planrechts benutzt werden. Als Ausgangsklassen für die Spezialisierung können entweder Basisklassen des XPlanGML Objektmodells wie BP_Flaechenobjekt oder fachspezifische Klassen wie BP_BaugebietsTeilFlaeche benutzt werden. Abb. 1 zeigt zwei Beispiele, wie auf diese Art und Weise Baugebiete modelliert werden, die nach der Hamburger BPVO von 1938 festgesetzt sind (BP_BaugebietsTeilFlaeche_FHH), sowie Flächen ausgewiesen werden, die keine Nutzung haben oder von jeder Bebauung freizuhalten sind (BP_SonstigeFestsetzung_FHH).

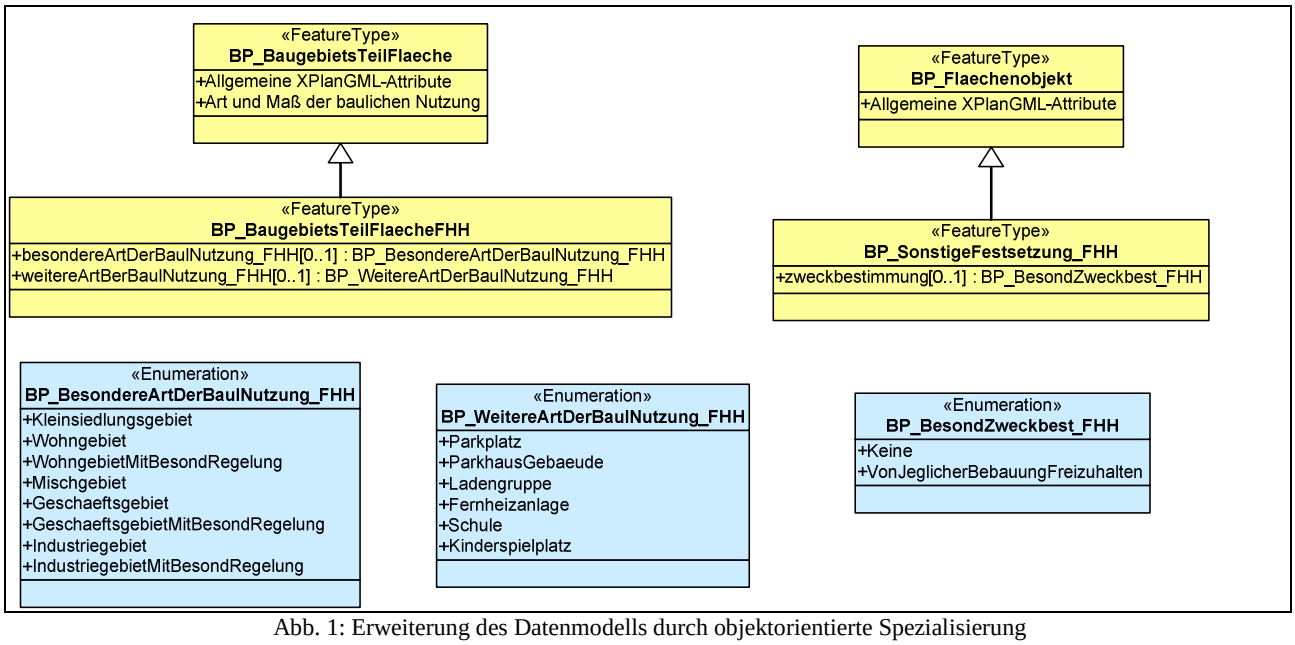

Abb. 1: Erweiterung des Datenmodells durch objektorientierte Spezialisierung

In den abgeleiteten Klassen stehen alle Attribute der Basisklasse (Raumbezug, Höhenangaben, Referenzen auf externe Dokumente, Maß der baulichen Nutzung, …) zur Verfügung, sowie zusätzlich die spezifischen Attribute der Erweiterung. Der zentrale Nachteil des Vererbungsmechanismus ist, dass die abgeleitete Klasse immer einen anderen Namen als die benutzte Basisklasse hat. Beim Datenaustausch mit Systemen, die nur den Basisstandard XPlanGML implementiert haben, werden Objekte der Klasse BP_BaugebietsTeilFlaeche_FHH deshalb im Regelfall nicht als spezielle, nur auf anderer gesetzlicher Grundlage ausgewiesene Bauflächen erkannt. Die Objekte dieser Klasse können von Standardsystemen nicht interpretiert werden und gehen beim Datenaustausch eventuell verloren.

4.3 Erweiterung durch eine Application Domain Extension (ADE)

Der Mechanismus der Application Domain Extension (ADE) wurde für das CityGML-Datenmodell (CityGML 2008) entwickelt und ist Bestandteil des OGC-Standards CityGML 1.0. Er dient dazu, den Basisstandard mit möglichst geringen Einschränkungen der Interoperabilität applikationsspezifisch erweitern zu können. Unter anderem existieren ADEs zur Lärmschutzkartierung (Czerwinski 2007) sowie zur Modellierung von unterirdischen Objekten oder Brücken. Einige dieser Erweiterungen sollen in der nächsten Version CityGML 1.1 in den Basisstandard aufgenommen werden.

Jede ADE wird durch ein eigenes XML-Schema spezifiziert, so dass die Gültigkeit von Instanzdokumenten einer ADE automatisch geprüft werden kann. Eine ADE gestattet es, neue semantische Klassen durch Spezialisierung von Klassen des Basisstandards (siehe Kap. 4.2) zu bilden. Zusätzlich ist es aber auch möglich, eine existierende Klasse des Basisstandards durch zusätzliche Attribute zu ergänzen. Die ADE Erweiterung des XPlanGML-Datenmodells zur Abbildung von Baugebieten nach der Hamburger BPVO zeigt Abb. 2. Entscheidend ist, dass auch in der Erweiterung der Klassenname „BP_BaugebietsTeilFlaeche“ verwendet wird. Damit kann jede Software, die den Standard XPlanGML unterstützt, die zugehörigen Objekte und die verwendeten Standard-Attribute verarbeiten. Die ADE erweitert die Attributierung von BP_BaugebietsTeilFlaeche um zwei spezifische, nur innerhalb der FHH relevante Attribute, die von Standard-Implementierungen überlesen werden.

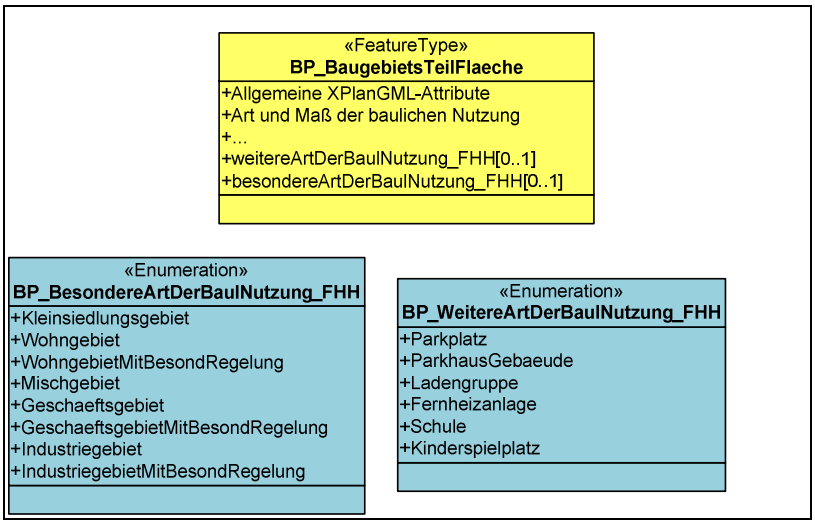

Abb. 2: Erweiterung mit Hilfe einer ADE

Damit ein Standard wie XPlanGML mit einer ADE erweitert werden kann, muss das zugehörige XML-Schema modifiziert werden (CityGML 2008). Die Modifikation beschränkt sich aber darauf, die vorhandenen Klassen um zusätzliche abstrakte Attribute zu ergänzen, die dann der ADE als Ansatzpunkte für die Erweiterung dienen. Damit hat die Modifikation keinerlei Auswirkungen auf Instanzdokumente des Basisstandards.

5 XPLANGML ERWEITERUNG „HISTORISCHES HAMBURGER PLANRECHT“

Wie schon erwähnt muss das XPlanGML Datenmodell zur vollständigen Abbildung des Hamburger „Digitalen Informationssystem Planung“ erweitert werden. Dies geschieht am zweckmäßigsten durch eine problemgerechte Kombination der standardinternen Öffnungsmechanismen (Codelisten, Generische Objektklasse, s. Kap. 4.1) mit einer speziellen ADE (s. Kap. 4.3). Im Einzelnen sind die folgenden aufgeführten Erweiterungen bzw. Anpassungen notwendig.

- Zur Unterscheidung der Festsetzungen nach aktuell gültigem Planrecht von Planinhalten, die auf historischem Planrecht beruhen ist es notwendig, zumindest bei letzteren die rechtliche Grundlage zu spezifizieren. XPlanGML hat dafür das Attribut „gesetzlicheGrundlage“ der Basisklasse „XP_Objekt“ vorgesehen, das in allen Fachobjekten spezifiziert werden kann. In XPlanGML 4.0 wird der Wertebereich dieses Attributs durch eine Codeliste spezifiziert, die um die Einträge „BPlanG 1923“, „BPVO 1938“ und „AufbauG 1949“ zu ergänzen ist.

- Der spezielle Typ eines Bebauungsplans wird im Datenmodell durch die beiden Attribute „planArt“ (Enumeration) und „sonstPlanArt“ (Codeliste) der Klasse „BP_Plan“ spezifiziert. Die Enumeration umfasst nur BPlan-Typen nach heutigem BauGB, zur Abbildung eines auf älterem Planrechts beruhendem Plans ist die Plan-Art „Sonstiges“ zu verwenden. Die Codeliste muss um die Einträge „Fluchtlinienplan“, „Durchführungsplan“, „Teilbebauungsplan“ und „Baustufenplan“ ergänzt werden.
- In Hamburger Bebauungsplänen bis 1970 wurde teilweise nicht zwischen den Nutzungen „Landwirtschaft“ und „Forstwirtschaft“ unterschieden (Kirchenbauer 2009). Deshalb können diese Festsetzungen nicht durch die XPlanGML Klassen „BP_Landwirtschaft“ bzw. „BP_WaldFlaeche“ modelliert werden. Die historischen Ausweisungen haben im DIP keine weiteren Attribute und können damit prinzipiell durch die generische Klasse „BP_GenerischesObjekt“ abgebildet werden, wenn die Codeliste „BP_ZweckbestimmungGenerischeObjekte“ um einen Eintrag „Land- und Forstwirtschaft“ er-weitert wird.
- Die Modellierung von Baugebieten nach BPVO kann durch eine ADE-Erweiterung der Klasse „BP_BaugebietsTeilFlaeche“ erreicht werden (s. Kap. 4.3).
- Zur Abbildung der restlichen Inhalte des DIP sind noch drei neue Klassen notwendig, die durch eine ADE-Erweiterung des Basisklasse „BP_Flaechenobjekt“ gebildet werden können:
    - „BP_Aussengebiet_FHH“ zur Abbildung von Außengebieten nach BPVO; die spezielle Nutzung der Außengebiete (Sportplatz, Kinderspielplatz, …) wird durch ein Enumerations-Attribut abgebildet;
    - „BP_SonstigeFestsetzung_FHH“ zur Abbildung der Festsetzungen „Keine Nutzung“ sowie „Von jeglicher Bebauung freizuhalten“ (s. Kap. 4.2);
    - „BP_BesondereZweckbestimmung_FHH“ für nicht näher differenzierte Flächen in Altplänen, die verschiedenste Nutzungen aus dem Bereich Gemeinbedarf und Ver- / Entsorgung haben.

6 ZUSAMMENFASSUNG UND AUSBLICK

Die vollständige Erfassung aller Inhalte des Hamburger „Digitalen Informationssystem Planung (DIP)“ ist mit dem XPlanGML Datenmodell, das auf den Inhalten der aktuellen, bundesweit gültigen Planungsgesetzgebung basiert, nicht möglich. Viele Inhalte des DIP geben Planfestsetzungen nach älteren Landesgesetzen wieder. Diese Festsetzungen sind weiterhin rechtlich gültig, auch wenn die zugrunde liegenden Gesetzeswerke inzwischen durch Bundesgesetze abgelöst wurden. Die zugehörigen Inhalte des DIP können deshalb im Datenformat XPlanGML nicht adäquat wiedergegeben werden.

Der Beitrag hat deshalb verschiedene technische Möglichkeiten zur Erweiterung des Standards aufgezeigt. Neben den im Standard bereits angelegten Erweiterungsmechanismen von Codelisten, generischen Objekten und generischen Attributen wurde dabei vor allem auf Application Domain Extensions (ADE) eingegangen. Diese Technik wurde für den OGC-Standard CityGML entwickelt und lässt sich leicht auf XPlanGML übertragen. Die vollständige Modellierung des historischen Hamburger Planungsrechts ist am besten mit einer Kombination standardinterner Erweiterungen mit einer geeigneten ADE zu verwirklichen.

Der ADE Erweiterungsmechanismus bietet im XPlanung Kontext noch vielfältige weitere Anwendungsmöglichkeiten. So bräuchten zukünftige landesspezifische Datenmodelle für die Regional- oder Landschaftsplanung nicht mehr im Rahmen des bundesweit gültigen Standards XPlanung definiert und gepflegt werden, sondern dezentral als ADE-Erweiterung der jeweiligen Kernmodelle. Auch zur Erweiterung des Standards auf andere Fachplanungen bietet es sich an, diese zunächst außerhalb des Standards als ADE zu definieren, die bei Bedarf leicht in eine neue Version des XPlanGML-Basisstandards überführt werden kann.

KornetCity: An Operational Model for Belgrade, Serbia

Maja Dimitrijevic, David C. Prosperi

(Maja Dimitrijevic, CITYPLAN, majaditri@gmail.com)
(David C. Prosperi, Florida Atlantic University, Fort Lauderdale, FL, USA, prosperi@fau.edu)

1 ABSTRACT

KornetCity is a conceptual model that focuses on reducing start up and operational costs for small and medium enterprises by equipping office buildings in mostly residential areas. The conceptual model has the advantages of reducing the need for traditional transport investments, parking, and reduced GHG emissions. In this paper, the conceptual model is further elaborated for the specific case of Belgrade, Serbia. Here, the focus is on contextual economic conditions (described and analyzed in terms of economic cluster theory applied to tertiary sector), occupational characteristics (described and analyzed in terms of the local occupational structure and potential areas of strength), and the distribution of potential office buildings. Three typical "kornets" – based on a sector-occupational characterization – are described.

2 INTRODUCTION

The prospects for urban planning, particularly efforts that rely on urban technologies, on being able to help create liveable, healthy and prosperous cities for everyone require, at their core, some notion of economic processes. Economic opportunity is a fundamental principle of the current, market-oriented global economy. In the current world, economic opportunity ranges from global businesses to the local entrepreneur who "fills in the agglomeration effects" necessary for the global businesses to compete successfully. That is, global businesses rely on the existence of a local pool of small and medium size enterprises (SME) to fill in necessary pieces of their production function, ranging from idea creation, to idea visualization, to printing, advertising, and negotiation. A major problem facing these small and medium size firms is the entry cost into the market of firms and capital.

KornetCity is a conceptual model that focuses on reducing start up and operational costs for small and medium enterprises (Dimitrijevic, 2008; Grozdanic and Dimitrijevic, 2009). There are two key ideas. The first is to provide the office space in pedestrian distance for the people working in the tertiary sector that mostly perform their work using computers. There are two ways of doing that: by constructing new Kornet office buildings or by reconstructing the vacant and/or underutilized buildings located in or near residential areas. In virtually every medium sized city in Europe there is a ring of vacant and/or underutilized buildings around a revitalized core. These buildings create dark spaces between the revitalized core and the nearby residential districts. The second idea is to equip office suites in these buildings with the IT functionalities necessary to carry out the business aspects of small and medium size firms. Similar to the efforts of IBM and CISCO in promoting the use of technological innovations to solve urban and metropolitan issues, KornetCity is based on the idea of individual "kornets" – individual office suites appropriately equipped. The very first "kornet" is currently in the seed stage of development in Belgrade, Serbia.

The expected results of using the Kornet concept is to create a more balanced level of development in the whole territory of cities than it is the case today in most of them (i.e. "city" zones with concentrated office buildings). Such a scheme could reduce the number of passengers that participate in every day commuting in motor vehicle traffic in cities, the time and money people spend commuting, GHG&CO2 emission caused by motor vehicle traffic, re/construction costs of office buildings and last, but not least reducing the start up and operational costs for small and medium enterprises. The bottom line is that this concept offers a more efficient (public budget savings!) way to development.

The purpose of this paper is to demonstrate how the idea of KornetCity, originally created as an advocacy position by the firm CITYPLAN, is and can be further grounded within mainstream economic strategies and policies consistent with the workings of the contemporary global economy. The paper is organized as follows. In the next section, we review the major theoretical treatments of role of small and medium size enterprises in the overall competitiveness of urban areas, including considerations of economic cluster theory and the role of the IT sector. This is followed by a general discussion of the KornetCity concept. The research problem here is to develop an operational model of the KornetCity concept based on the characteristics of the Belgrade's economic status and potential. The penultimate section contains three

typical "kornets" – for a creative office, for a government-like service office, and for a producer service office. The final part of the paper presents an overview of results, our contribution to the literature, and suggestions for future research.

3 THE ROLE OF SME'S IN THE ECONOMIC "PRODUCTION FUNCTION"

Here, we do two things. First, we review prevailing literature regarding the creation of a sustainable economic structure for metropolitan regions, focusing on the role of small and medium size enterprises in economic processes. Second, we provide a brief overview of the economic characteristics of the Belgrade metropolitan region

3.1 Theory of Small and Medium Size Enterprises

The role of small and medium enterprises (SME) in the economic production function of a city region is often overlooked in an era that focuses on globalization and transnational corporations. The hard reality is that in most economies, small enterprises are major players. One recent estimate contains the following "parameters": globally, 99% of all businesses are small and medium size enterprises, they account for 40%-50% of GDP; in the EU, SME's comprise 99% of all firms and employ over 65M people (http://en.wikipedia.org/wiki/Small_and_medium_enterprises, accessed 5 February 2010).

The term SME, and its close associate SMB, is in common use throughout both the developed and developing world. As is a common problematic, the term has many definitions, depending on country or place. The EU has attempted standardization as follows: micro (fewer than 10 employees), small (those with fewer than 50 employees) and medium (those with fewer than 250 employees). Another interesting term is SOHO that describes "small offices" of fewer than 10 employees. Very little is really known about these SOHOs.

The importance and role of SMEs in the overall economic production function raises a number of important strategic and economic policy questions, one of which is the general economic issues of "ease of entry" into the marketplace" with its often-associated corollary "start-up costs" or "investment capital".

Finally, their role in the economic production function of metropolitan regions is related to principles of economic cluster theory, aspects of the occupational structure including attributes of the creative economy, and the potentials of the IT sector to promote urban growth.

3.1.1 Cluster Theory

The most important stream of strategic thinking and research is economic cluster theory. Two attributes of cluster theory are particularly important. First, that "clustering" is normatively the (only) mechanism that could guarantee economic success. Notice that a cluster does not necessarily guarantee economic success, but success cannot be achieved without clustering. Second, that there is NOT a direct correlation between "concentration of economic activity" and "economic cluster." Magnitude of employment in a specific place may or may not be for example a competitive arrangement but simply co-location of activities. The case of a declining shopping center is sufficient to make the point.

Three cluster theorists provide guidance for how to know and measure the existence and value of a set of economic activities. Porter's industrial cluster theory (2002) and its application to urban areas (1995) appear most appropriate for the design of new clusters. Yet clusters are more than unsubstantiated policy tools and can be empirically verified. At the evaluation level, Van den Berg et al. (2001) provides a clear set of intuitive criteria to assess existing and emerging clusters. Focusing on different sectors (cultural, electronics, telecommunications, health, media, and tourism), Van den Berg et al. lay out three broad potential criteria. They, and their components, include: (1) spatial economic conditions (strong local demand, intra- and inter-regional accessibility, quality of life, and 'cultware'); (2) cluster specific conditions (initial size and development, cluster engines, strategic interaction, and level of new firm formation); and (3) organizing capacity (strong shared vision, political/social support, and public-private partnerships). Finally, Mommaas (2004) is concerned with "place-based development." Mommaas' criteria to evaluate clusters include: horizontal aspects; vertical aspects; internal organization factors; external organizational factors; integration and/or openness; specific development paths; and spatial organization. These are all recognizable terms in the language of agglomeration and urbanization economics (cf. Bogart, 1998). Mommaas then examines these criteria in terms of five attributes of overall development practice including: (1) strengthening the

identity, attraction power and market position of places; (2) stimulating a more 'entrepreneurial approach, (3) stimulating innovation and creativity, (4) finding a new use for old buildings and derelict sites, and (5) stimulating cultural diversity and cultural democracy.

3.1.2 Creative Enterprises

Once again, there are three theorists that dominate this arena. First, Howkins' The Creative Economy: How People Make Money from Ideas (2001) focuses on industrial groups and employment categories deemed "creative." His fifteen industrial sectors are (quoting from Florida, 2002, p. 47): R&D, Publishing, Software, TV and Radio, Design, Music, Film, Toys and Games, Advertising, Architecture, Performing Arts, Crafts, Video Games, Fashion, and Art, listed in descending order of global expenditures. The message is clearly one of "creativity at work": those industrial sectors covered by intellectual property law – aspects of law that cover patents, copyrights, trademarks, and designs (Healy, 2002).

Landry's The Creative City (2004, in its fourth edition since 2000) is one of the mantras of local politicians and economic development practitioners. Landry's book and practice (www.comedia.org.uk) emphasize place. The descriptions and precedents are particularly useful in the UK and other European contexts where the planning of cultural quarters (one, but not the only, use of the word "creative") is an instrument of downtown revitalization. Any benefit to the economy is, at best, circumstantial. A number of scholars have described, evaluated and/or suggested improvements to this kind of practice (e.g., McCarthy, 2005).

Finally, Florida's Who's Your City (2008), based on concepts and ideas originally developed in Rise of the Creative Class (2002) focuses on occupations and characteristics of workers, particularly in the "creative" class. There are arguably three basic premises. First is that the economy can be broken down into four or five categories of workers, defined on the basis of occupations, some of which are called "creative." The creative group is composed of two groups – the super-creative and the (merely?) creative. Second, over the long term (roughly the 20th century) the proportion of the total working in these classes of occupations has been rising. Third, and perhaps most controversially, that this class is responsible for growth and that this class is "attracted" to places that are well endowed with talent, technology and tolerance (the 3 T's) of economic development.

Taking a somewhat broader and empirical approach, Prosperi (2005) examined the distribution of the set of creative firms in the South Florida context. The key point is that all creative firms do not have similar locational attributes. Some prefer the center city location; others more suburban locations. Among those preferring center city locations are lawyers, architects, and other firms that tend do business with governments.

3.1.3 THE IT DIMENSION

The literature on the role of the IT revolution (e.g., Castells, 1996) and sector on urban growth, form, and liveability accounts is voluminous. The trilogy of work by Audirac (2005, 2003, 2002) presents a general overview of the contours of the debate. The general literature points to two "opposite effects": the concentrating effect (agglomeration economics are still important and since IT is the new 'capital' of business operations it must be part of the urban-oriented business location decisions) and the deconcentrating (distance is irrelevant as long as the business is hooked up with the virtual world; people can work from anywhere). More specifically, the IT revolution points to both the "potential reconcentration of certain activities but also to the furtherance of exurban development, sociospatial segregation and traffic gridlock" (Audirac, 2005, p. 212).

Since there is no clear cut answer, the key is to uncover specific synergies in specific contexts – probably based in the principles of economic cluster theory, as above. Yet, a careful tracing of the types of firms that are likely to benefit from center city locations has not been attempted empirically, other than location studies like the empirical findings of Prosperi (2005) above.

In such an environment, it is not surprising that the real estate and IT infrastructure sectors have responded with the twin notions of "smart buildings" and "smart social consciousness". Smart buildings (capable of supporting high end computer systems as part of the building infrastructure) are not new. The clustering of smart buildings into advanced office park for creative, IT dependent, workers is a hallmark of contemporary economic development strategies. What is becoming newer is the notion that the IT providers are developing applications to direct "smarter" decisions. The IBM Smarter Planet campaign

(http://www.ibm.com/smarterplanet/us/en) seeks to work with clients to make the world "smarter" by working on systems to improve performance on roadways, health care, power grids, and food production, among others.

3.2 Belgrade and the Belgrade Region

As the EU expands, cities and regions in central and eastern Europe (CEE) are attracting increasing attention, both academically and professionally. For example, Hirt (2009) outlined the development path of Belgrade focusing on five periods of growth and change the most recent being communist, transitional, and contemporary and shows how its recent past is marked by abrupt shits in political status from a capital of a relatively small nation-state, to a center of larger and prosperous multi-national federation back to a capital of a nation-state. Arguably, economic development policies and strategies are context sensitive; the search for competitive and comparative advantage is at least partially determined by local territorial capital.

There is a Master Plan for the City of Belgrade 2001-2021 (Belgrade Land Development Public Agency, 2003). In the subsequent draft SMART PLAN – a transportation plan (Belgrade Land Development Public Agency, 2008), planners conducted a background analysis comparative study of "comparable" cities. Comparable means populations between .7M and 2.1M and include: Bucharest, Vienna, Glasgow, Copenhagen, Helsinki, Lyon, Munich, Prague, Stockholm, and Torino. The analysis was conducted for twelve other variables including: share of work places in city central zone, GDP per capita, motorization ratio, mobility rates, length of road network per 1000 inhabitants, parking lots per 1000 work places in the city central zone, public transit vehicles, modal split, average road speed, average public transit speed, and a ratio of speed on road v. transit. According to this report, Belgrade has the highest proportion of jobs in the central business district and the highest percentage of workers travelling by public transport (53%), and about average percentages of people walking to work. But Belgrade also has the lowest GDP per capita, motorization ratio, mobility rate, road network length, number of downtown parking lots, average travel speed on public transportation, and share of financial assistance to allocate to transport, and number of downtown parking lots. However, the ratio of road speed/public transport speed is second, lagging only behind Torino. Interestingly, only Munich has a negative number on this indicator, meaning that it is the only city among the comparables in which public transportation speeds are higher than road speeds.

3.2.1 Some General Population Characteristics

According to Wikipedia, the population recorded in the 2002 census revealed a population of 1.576M in the "larger-city" area and 1.273M in the "inner-city" area. Recent polls show that the "larger-city" area has increased by 400K in just five years, yielding an official estimate in 2007 of 1.63M. The "inner-city" area, which is consistent with the political boundaries of the City of Belgrade, has, according to Master Plan (2003, chap 1.3.2, table 1) a population of 1.352M in 2005. The official planning estimate by this agency predicts an "inner-city" population of 1.4M by 2021, an estimate that is probably too low.

The population is spread over 17 municipalities, ten of which belong to the "urban zone": Vracar, Stari Grad, Savski Venac, Novi Beograd, Cukarica, Zvezdara, Palilula, Zemun, Rakovica and Vozdovac. The largest in terms of population is Novi Beograd (218K); the smallest is Sopot (20K) in the suburban zone. The geographic extent of the metropolitan area is 3.22K sq km; the city is 396 sq km. Simple calculations reveal a population density of the "inner-city" area of approximately 3414 persons/sq km. This makes it equivalent to Vienna, and higher than Glasgow, Munich (3100), Glasgow, Budapest (2550), and Helsinki (2100), (source: http://www.citymayors.com/statistics/largest-cities-density-125.html).

3.2.2 Economic Sector Analysis

Belgrade is located in the center of South East Europe, at the intersection of the strategic Pan-European transportation corridors No 10 and No 7 linking western and central Europe with the Middle East. It lies at the confluence of the Sava and Danube rivers. The Belgrade airport contains direct connections to 43 European and Asian cities.

Belgrade was the winner of a competition for cities and regions of the future in 2006 and 2007 organized by the Financial Times magazine (other winners were: Paris, Western Europe; Brno, central Europe; Baku, Eastern Europe; and London, northern Europe). This award is based on criteria such as economic potential, operating costs, human resources, transport, IT/telecommunications, and quality of life for foreign investors.

Today, it is estimated that over 35% of Serbia's GDP is generated by the city, which also has 31.4% of the employed population. Belgrade is the most economically developed part of Serbia and is home to the country's National Bank. Other notable companies include Jat Airways, Telekom Srbija, Telenor Serbia, Delta Holding, Comtrade group. Belgrade is a regional center for Societe Generale, Asus, Intel, Motorola, MTV Adria, Draft Foods, Carlsberg, Microsoft, OMV, Unilever, Zepter, Japan Tobacco, P&G, and others (http://en.wikipedia.org/wiki/Economy_of_Belgrade).

Recent studies by Danos Consulting (2009) indicate a number of macroeconomic trends from 2006 through 2009; they are shown below in bullet form:

- GDP has grown by 25%.
- GDP/capita has risen from 3.278 to 4.186 Euros.
- Exports of goods have increased over 200%; imports have declined (but these numbers are particularly sensitive to an "end point" bias, reflecting unique activity in 2009).
- Foreign direct investment in the aggregate and as a percentage of GDP is declining, but not as fast as the "end point" bias would suggest).
- Unemployment has declined somewhat.
- Inflation is higher in the post 2007 fiscal environments.

Some other characteristics, culled from the Master Plan except where noted, are shown below in bullet form:

- The size of the consumer market is 1.7M (source: current market estimates provided by Danos International).
- The ratio of employed persons to total population is .403 (545K/1.352M).
- Of these workers, 73.55% work in the tertiary sector (so, approx 401K). The average monthly income per capita is 47,500 dinar (572 Euros, 903 dollars). Updated numbers suggest monthly grosses of 59,897 dinars (746 Euros, 1082 dollars) and nets of 42,901 (535 Euros, 774 dollars). The average GDP per capita is 10836 dollars in real terms and 18204 in terms of purchasing power parity (http://en.wikipedia.org/wiki/Economy_of_Belgrade).
- There are 62 university-level institutions. Belgrade boasts well educated, fast learning, multilingual and IT literate labor force. Over 8K students graduate from Belgrade University every year, with 1/3 of them adding to the traditionally strong engineering base. According to Gallup International, the percentage of English speakers is the highest in the CEE, and an increasing number of western business schools open their affiliates in Belgrade.
- There are 3.5M trips per day in Belgrade, of which 16% or 530K are for business purposes. The modal split for the journey to work is: 59.07% public transportation, 24.75% private care, 13.87% walking, and 2.31% other.
- According to the Eurostat methodology, and contrasting sharply to the Balkan region in general, 53% of the city's households own a computer and 39.1% of households have an internet connection. These figures are above those of the other regional capitals such as Sofia, Bucharest and Athens. (http://en.wikipedia.org/wiki/Belgrade).

According to Danos, the office market in Belgrade increased between 2008 and 2009 by 8% and now represents approximation 700,000 sq m. Most of this development is in Novi Beograd, with the notable exception of the B2 building in the traditional downtown. The B2 was developed in partnership with Cisco, a leader in the IT industry, has connected IT and real estate development in an attempt to reduce both operation and energy costs. In 2008, the intelligent building B2 was opened. B2 is an almost 24,728 sq m (approx 2.5M sq ft) complex that combines a shopping mall, offices, residential and business apartments with four levels of underground parking. The idea is to create a world-class living and working environment in a smart building that can be operated in a cost- and energy-efficient ways with high levels of physical security. At the heart of the approach is a service-oriented network architecture designed to reduce costs and complexity by replacing formerly disparate systems with one simplified, flexible and scalable Internet Protocol (IP) network. The estimate is that this approach can reduce capital costs by 20-25%, total operating costs by 30%, including a 40% reduction in energy consumption. With significant technological capacity,

this project is targeted at high end residential consumers and firms. However, the office space in this building is only 4K sq m. .

The following data come from the Economic Potential Report obtained from the City's website. They are also highlighted in bullet form:

- Among registered businesses, there are approx 53K businesses and 48K entrepreneurs
- Among the municipalities, Novi Beograd has the largest number of companies and entrepreneurs (9642 and 6689, respectively)
- Stari Grad has the second largest number of companies and the second lowest number of entrepreneurs; Zemun has the third least number of entrepreneurs.
- Among the municipalities in the urban zone, the municipalities with the largest number of entrepreneurs (and hence possible tenants for a KornetCity type activity are: Cukarica, Palilua (which has the second lowest number of "companies", Vozdovac, and Zvezdara.
- Among SME firms, the largest percentages are in "trade, including repair", real estate business and renting, and construction. Of these, only real estate is a tertiary sector activity. Government, health care and social protection, and personal and social services are other possibilities.

4 THE KORNETCITY CONCEPT

The KornetCity concept has several basic building blocks: work spaces, notions of a business plan, and when applied to a geographical locality a geographical distribution based on gravity flows of workers. Each is discussed in turn.

Regarding work spaces, the concept seems to connect the best characteristics of work in the office and work from home. It is especially appropriate for SOHO type businesses, particularly during their start up stage. These work spaces are particularly appropriate for firms and/or occupations that rely on the use of the computer as a principle source of work material. These work spaces are called and are equipped as a NetCell, that is, a place that has all necessary software, hardware, and internet connection as well as sufficient information flow for conference connections to be performed without interruption. These NetCells are aggregated into a specific "kornet" or specific office building.

Regarding the notion of business plans, the KornetCity concept relies on the idea that working in Kornet provides the possibility of renting software per usage, that is, "you pay exactly what you use". This enables the usage of any kind of software with a certain fee. This way software would become economical and legally more accessible which would improve the level of informatics literacy of the population.

Regarding the notion of geographic distribution based on the gravity flow of workers, the basic idea is that these buildings could be spread over the city at a distance of up to 1.6km from each other. This distance is equivalent to a maximum commuting distance of up to 800m, which represents a 10 minute walking distance.

4.1 A Proto-typical Kornet Building

"The schematic appearance of Kornet building exposes differences from traditional office building in the level of integrity of ICT installations. This is shown in Figure 1.

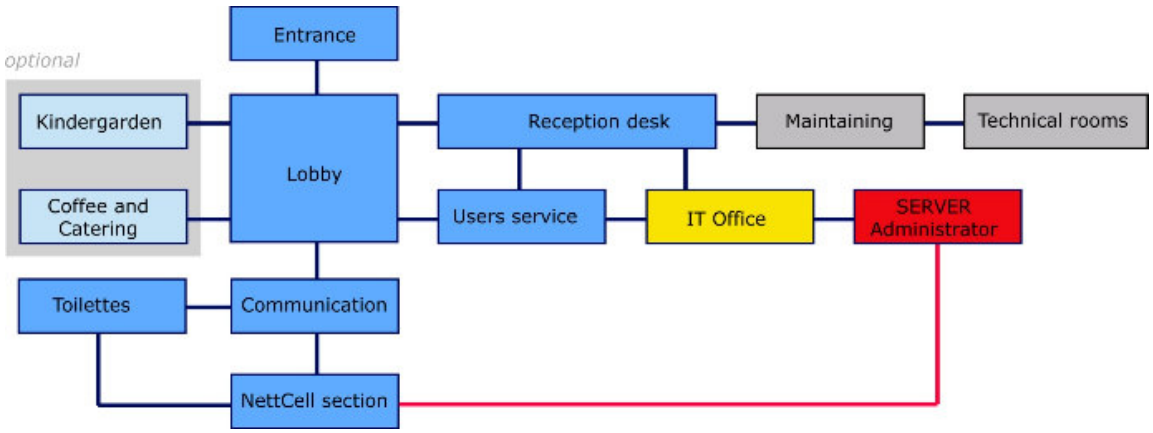

Figure 1: Schematic Presentation of Kornet Office Building Organization

4.2 Business Model

Grozdanic and Dimitrijevic (2009) have argued that KornetCity should be acceptable and convenient for SME and SMB, especially for startup investments.

At the beginning of an entrepreneurial activity, a fundamental idea is that the scope of work and the extent of business will expand. The entrepreneur needs to buy or rent work space. The typical tendency is to both: (1) find space that is usually bigger than current company currently needs, and, (2) buying more software and hardware.

In the Kornet City model, the company rents only what it currently needs, which provides a usage rate of 100%. No matter if the number of employees is increasing or decreasing, this does not require change of company's residency and increased investments in office space. Hardware and software is always 100% used and is most economically and ecologically justified.

4.3 A System of Kornets

Grozdanic and Dimitrijevic (2009) have shown that a system of fully occupied "kornet" buildings distributed at 1.6km apart would decrease traffic in Belgrade and reduce GHG by 8%. These results are based on the notion of capturing employees who would work near their residences. The value of the KornetCity model is based on the transfer of a large percentage of work trips from "mechanized" to "walking".

5 RESEARCH PROBLEM AND METHODOLOGY

What has been missing to date is some firm understanding of the types of firms, and the reasons why they would consider KornetCity considerations. To now, the assumptions are based on market share. To add meat to the overall proposal, this paper begins to focus on what kinds of firms, and what outfitting is needed. The previous work is extended by inclusion of graphic representations of what a Kornet NetCell might look like, and consideration of what the "outfitting" might look like for three proto-typical potential users.

6 RESULTS: AN OPERATIONAL MODEL FOR BELGRADE, SERBIA

There are two major results. The first is general design ideas for basic and advanced NetCells. The second is a description of how these could work for three proto-typical types of firms.

6.1 Designing Typical Kornets for Belgrade, Serbia

Here, we discuss the interior design of a kornet NetCell, and basic ICT considerations for these NetCells.

6.1.1 Basic Rendering of Basic and Advanced Net Cells

A kornet building is based, initially, on the idea that there are two basic types of potential users: basic and advanced. The Basic NetCell has minimal dimensions of 3.0x1.7m (5.1m2). Natural light is provided. The interior design would cost less than 450 Euro/m2 (current Belgrade Fit Out costs). Acoustic insulation between NetCells performed in the rank of sound-proofing as in the standard offices.

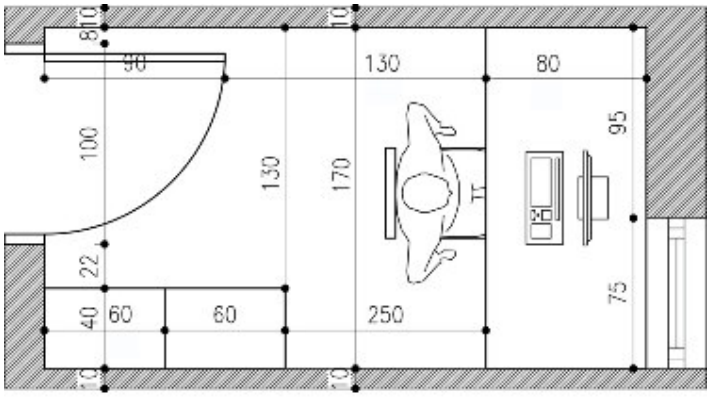

Figure 2: Basic NetCell Layout

The Advanced NetCell has minimal dimensions of 3.0x2.7m (8.1m2) with a window offering a good view. The interior design would cost between 600 and 800 (current Belgrade Fit Out costs), Euro/m2 areal and aesthetic higher quality of office space. A workstation chair that can be converted to a comfortable berth chair in a horizontal position for brief moments of rest or an area designed for coffee breaks. Acoustic insulation between NetCells provides better sound proof conditions (for the need of the specific occupations (radio DJ, musicians, necessity for higher confidentiality when the information needs to be exposed/delivered through talking).

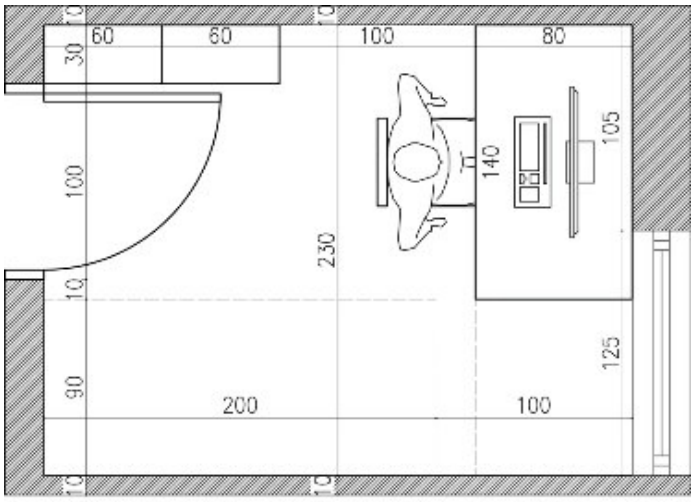

Figure 3: Layout of an Advanced NetCell

6.1.2 ICT parameters for Basic and Advanced Net Cells

The Basic NetCell would have standard network data flow capacity, including those normally used by public service employers (monitor, mouse, keyboard, and other peripherals). Expected users would be: employees of regular importance in companies as well as “additional workers” that could be called in for temporary spikes in workload. These users deal with information up to medium levels of importance.

The Advanced NetCell would have maximum data flow capacity, high level of data transfer security, high quality hardware (large monitors, exclusively latest hardware components, well-known and recognized brand manufacturer). Expected users would be: people running SME or people working as high positioned employees/consultants, etc. dealing with Information of medium to high level of importance.

6.2 Examples for Belgrade, Serbia

Both the theoretical discussions and the discussions of the Belgrade economic situation suggest that there are certain types of businesses that could benefit from a kornet type solution. The theoretical literature suggests very small, SOHO-scale firms in the creative, governmental, and some advanced producer services. Illustrative examples are provided for each.

6.2.1 Example 1: An Architectural or Similarly "Creative Office

The beginning of functioning of an architectural studio as a SOHO-SME considers for the start just one architect working in the studio (as the Owner). It requires the start up investment in Kornet service that includes office space (NetCell), IT support, fast Internet flow, certain level of data security, rent of software according the specific demands of user and usage of external services (printing of large format drawings, scanning, etc.).

During the start period of this architectural studio, the income is almost zero and the expenses in a classical office would demand the significant start up investment like renting a space for studio that would be appropriate for at least two more people for a period of at least twelve months (standard practice for rent agreement in Belgrade). In case of equipping this space with appropriate interior elements hardware and software (performed at the beginning of studio functioning), the risk of investment in an architectural studio is significantly higher than investment in same SME but located in Kornet.

In the first few months of functioning of architectural studio, the one who runs it will spend most of the time trying to get the business engagements. Possibility to work in Kornet as in business incubator provides many options that one SME at the beginning of functioning might experience as an advantage (gathering at the same place companies that might be seen as a potential partner rather than a potential competitor, sharing a "floor secretary", possibility to use meeting hall upon the necessity, IT services upon request and software renting etc.).

If or when the newly founded architectural studio obtains a job that requires the engagement of more than one architect, that creates the necessity to employ co-workers of a certain profile (additional architects, technicians, other engineers). The engagement of those people does not required that they need to be located in the same space, since almost all of their data exchange can be performed through the Internet. This kind of communication enables "additional workers" to work from Kornet that is closest to their home. Thus, the team could work on one project; communicate with no interruption but to be physically dispersed.

Since each of employees is working from his own cubicles, the investment in NetCell renting is always optimal for SME since the rent will last for as long as the employee works for SME. Thus, SME using Kornet is actually using their employees as "outsourcing" and the flow in the number of employees would not create the need for larger/smaller office space. As soon as the job is finished, SME will let go the "additional workers", until other work increase occasions.

6.2.2 Example 2: A Call Operator Service (as an example of a NGO Office)

This example uses a call operator service as an example of a NGO. The more specific association to the work of NGOs or local government is those call centers that are created in and during various sorts of political or public opinion campaigns.

In a call center office, there are two way communications. First, external communication that uses the telephone as major device for communication with users and second, internal communication that is processing collected data for clients. Contact with target group of people is mostly performed in verbal communication that creates a certain level of noise.

Operating the call center in the form of campaigns can last from few days to a few months. According to the specific need of a client, a call center is hired that provides a certain number of operators to the campaign of that client and designates them information they need to provide to target group. Thus, call centers employ large number of operators creating a pressure on spatial demand in classical call operator organization.

Moreover, there exists the possibility that, when work load increases, to disperse additional workers to a nearby Kornet office. That way, the external communication remains the same (telephone) and the internal communication is performed through the Internet connection with the headquarters of the call center.

6.2.3 Example 3: An Advanced Producer Service (Accounting, Legal, etc.) Office

The final example is that of an advanced producer service office such as an accounting or legal office. These services, like most administrative services have an obstacle of overcoming the prevailing preference for analogue form of documents. Still, the validity of electronic signature (the law of the validity of electronic signature was adopted in 2004 in Serbia) creates the expectation that these obstacles can be overcome and that the use of digital forms and electronic signatures will continue to grow.

Considering that, functioning of one accounting office in Kornet is possible today. Invoices could be sent through the internet and authorization of documents could be done in digital form. Since accountant, governance, legal, in one word – all administrative work has as ultimate obligation of archiving files thus, the potential usage of cloud computing (that Kornet could provide) could provide a significant benefit considering safe managing and storage of endless amount of data.

7 CONCLUSION AND EXTENSIONS

The KornetCity concept, previously postulated as a tool for reducing energy-dependent travel, is argued in this paper as a tool for economic development. It has placed the concept within the more general urban economic development literature, which among other things focuses on small and medium enterprises, the need for agglomeration economies, and the role of IT. Using the Belgrade, Serbia context as an example, the results are framed with the need for both design (characteristics of buildings, including the lack of parking spaces) and economic (what types of firms) considerations. Examples of three proto-typical kornet work spaces are provided.

Potential future research topics could include: (1) more "kornet" examples; (2) results of implementation of a "kornet"; and (3) a larger scale "economic" analysis. Each is briefly discussed. First, consider as an example of other types of kornet spaces, the game NetCell. Physically, the minimal dimension is 3.0x2.7m (8.1m2). There is no need for natural light. The orientation and view of the surrounding space is unnecessary and even undesirable. Interior design would cost less than 400 Euro/m2, since such things are of secondary importance. Acoustic insulation between NetCells should be of high quality. Such NetCells that do not require the natural light could be very useful tool in providing the maximum parameters in re/designing Kornet building in the high density constructed areas. The IT parameters include high network data flow capacity. Hardware equipment should provide excellent graphical solution – large high-resolution monitors, fast processors, etc. in short – expensive hardware. Additionally, specific equipment is needed – VR helmets/headsets, gloves, "weapons", steering-wheels, joysticks, and headphones. The option for on-line gaming should be anticipated – therefore, high-volume network data flow is required. The Game NetCell for gaming should be profiled, in terms of size, to the User in sitting position, as well as to allow the said User the room for limited maneuvering (leg se apart, crouching, jumping, lying down, simulation of sitting in a vehicle/a flying craft/on a motorbike, etc). Second, a pilot project underway, consisting of just 7 NetCells, "KornetCity: an IT Business Concept that reduces Motor Vehicle Traffic in Cities" has been endorsed by the European Commission's Sustainable Energy Europe Campaign as an Official Partner. (http://www.sustenergy.org/tpl/page.cfm?pagID=15&id=2698&submod=details). Monitoring and evaluation of this project, estimated to provide significant energy savings, will provide further empirical evidence of the usefulness of this approach. Third, it could be interesting to conduct two related studies: an inventory of potential "kornet" buildings – those that are available for such conversion as well as a much more detailed inventory of SOHO-type firms in the Belgrade context. The forthcoming paper by Dimitrijevic and Prosperi (2010) begins this line of research. The current research reported here indicated that certain sections of the Belgrade have more entrepreneurs than others, areas that would be particularly amenable to KornetCity solutions.

1 ABSTRACT

The compact Mediterranean city is undoubtedly synonymous with the sustainable and libeble city.

Barcelona, constructed in a relatively small area of 92 (square?) km, with a density of 16,000 inhabitants per square kilometer –still one of the highest in Europe–, represents a model that serves to put into question the relationship between the compact city and its administration. It is an administration that, up until Ildefonso Cerdà's 1859 [ensanche] urbanization project, has been understood as "forthcoming developments" leading to a compact and complex city.

Nowadays the first steps towards urban sustainability should include planning tools, understood as the supports that allow for forthcoming developments.

The big challenge for new master plans is to introduce progress made in other disciplines –far removed from strictly urban roots or disciplines–, highlighting those innovations that stress the sustainability of those planning instruments.

Thus, for a while now, urban planning has incorporated urban ecology recommendations, aiming for compacity, allowing for denser and more energy efficient urban patterns, clearly departing from low density, extensive models.

In the same way, the introduction of generous proportions of complexity or a higher diversity of uses and activities makes it possible to move away from the unintentionally single use functionality of exclusively residential areas. Mixed patterns promote social integration and diversity.

2 INTRODUCTION

Even though livability is primarily a subjective experience, and one of the main questions that planners are concerned with, there is currently a growing consensus regarding the characteristics of a livable city for designing livability.

In fact, cities are now emphasizing the importance of competing on the basis of livability and the quality of life offered, and it is becoming an increasingly important factor in modern business location decisions, especially among high technology and knowledge firms (Richard Florida, 2008).

Standard economic criteria for the livable city comes fundamentally from Mercer's Quality of Living Survey and from Monocle Magazine.

In the first case, they adopt 39 criteria that include safety, education, hygiene, health care, culture, environment, recreation, political-economic stability and public transportation. On the other hand, Monocle Magazine includes some non-scientific criteria, such as safety/crime, international connectivity, climate/sunshine, quality of architecture, public transportation, tolerance, environmental issues, access to nature, urban design, business conditions, proactive policy developments and medical care.

But the criteria adopted by citizens are, at least in part, different. The Livable City Organization has as its goal to help create "new community models that focus on the interconnected relationships among growth issues such as transportation, housing, environment, affordability, neighborhoods, culture and the economy in an equitable and sustainable manner".

But from the early 1960s, economists and planners such as Jane Jacobs, Gordon Cullen, Lewis Mumford and Kevin Lynch, who shared a mainly negative image of suburbanization after the massive construction during the 1950s and 1960s and during the first petroleum crisis in Europe and the United States, were focusing on the change in the meaning of the livability of public space, reclaiming, basically, the missing sense of identity in the territory (MOORE,C.W., 1965). More recently, Michael Sorkin (1992) demands a more

authentic urban reality, a city based on physical and cultural proximity (FREESTONE,R., GIBSON, 2006), beginning an appreciable chapter in the recuperation of public space. Relations of proximity that not only improve security on the street but also encourage economic and cultural creativity as a consequence of the fluidity of connections.

Our article stresses on idea of the importance of liveable and sustainable society, based on the relation of proximity, as one of the basic criteria of a liveable city inside compact city model linked to its territory. As Richard Florida (2009) explained a great city is not a big village, but a number of relationship that are multiply their potential

The manner in which Barcelona has developed through the expansion project of Ildefonso Cerdà in the middle of XIX centuries, which for almost a century was denied, may have a new interpretation in terms of liveability in a different and compact city.

2.1 The communication is divided into two sections

Interpretation of the project by the engineer Ildefonso Cerda, 1855-63 of Barcelona expansion and its actual construction, using criteria of the urban ecology as like compactness, complexity, efficiency, stability and social cohesion (BUSQUETS J., COROMINAS M, 2009; MAGRINYÀ, F., 2009; RUEDA, 1995)

The result is that the project includes some of the criteria of a good liveability like those we adopt nowadays in the era of globalization.

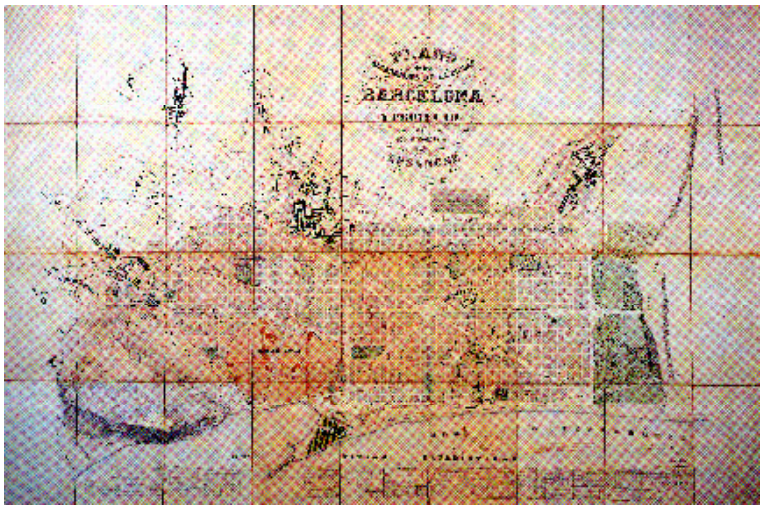

Fig. 1: Ildefonso Cerdà, Expansion project for Barcelona, 1859

Fig. 2: Barcelona, 2008

A prospective scenario for the Barcelona of the 21st century using criteria of urban ecology in particular made by the Agenzia di Ecologia Urbana of Barcelona(Rueda, 1995). It is an intentional model, based in the functional model proposed by Gatpac (Group of technical architects for Contemporary Architecture) in 1934,

that aims to lay down the patterns and the direction that Barcelona must follow in a process towards sustainability in the new information age

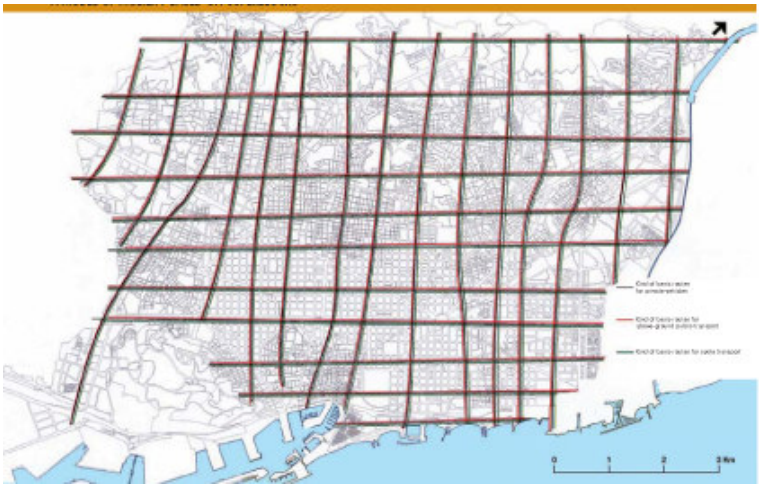

Fig. 3: Model of mobility based on superblock

Fig. 4: The public space that appears in the proposal of superblock

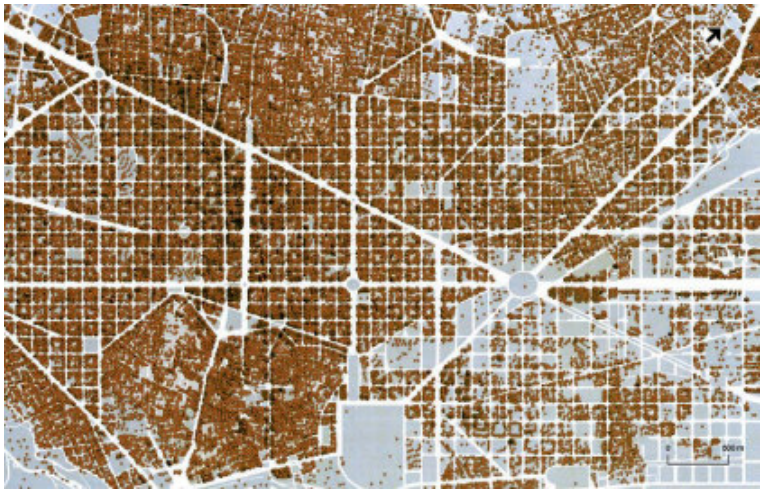

Fig. 5: Activity density of the superblocksuperblock

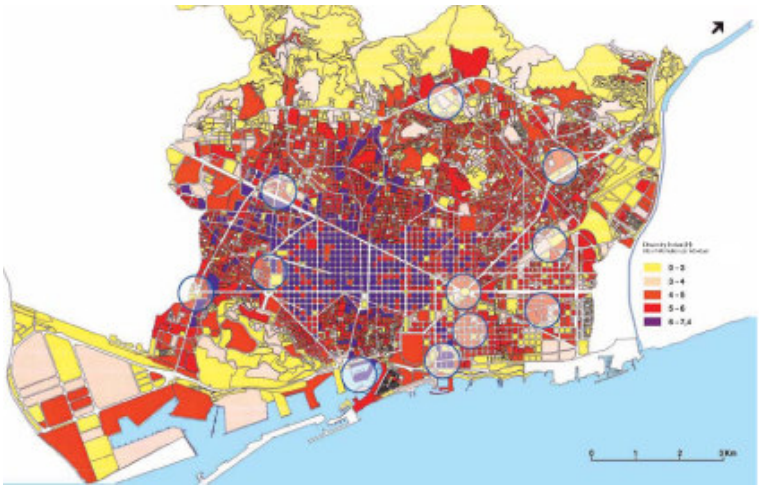

Fig. 6: Areas of new centrality

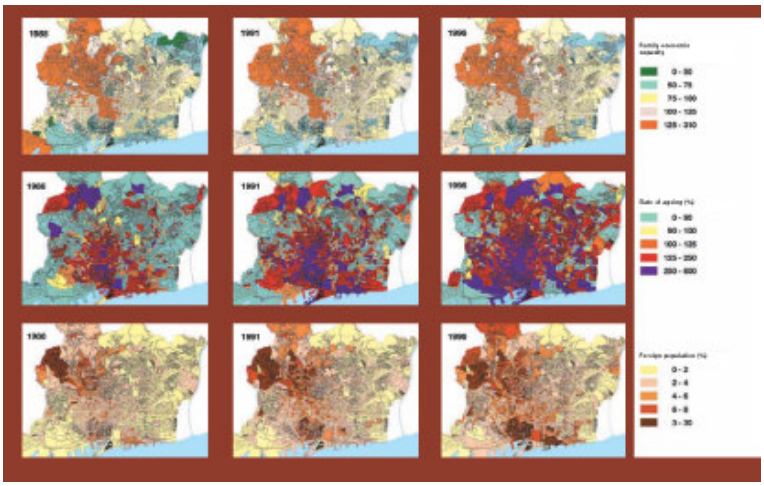

Fig. 7: Stability a social choesion

3 CONCLUSION

The project of Cerda, that this year is the 150 anniversary, has its first quality in to be a processual project with a big introspection abut which are the qualities of the mediterean city.

From the analysis of its evolution emerges that the history of the transformation of Barcelona teaches some objective for the mediterrean cites in order to preserve their liveability:

- To defend the compact and diverse city, with a public space of quality.
- To improve mobility and to make the street a welcoming environment.
- To achieve optimum levels of environmental quality and to become a healthy city.
- To increase social cohesion, reinforcing the mechanisms of equity and participation.
- To reduce the impact of the city on the planet and to promote international cooperation.
- To protect the free spaces and biodiversity and to extend the urban greenery.

Liveable and resilient Ho Chi Minh City: Tackling the challenges of climate change, energy security and sustainable urban development

Harry Storch, Nigel Downes

(Dr. Harry Storch, Brandenburg University of Technology (BTU) Cottbus, Department of Environmental Planning, Germany, storch@tu-cottbus.de)
(Nigel Downes, BTU Cottbus, Department of Environmental Planning, Germany, downes@tu-cottbus.de)

1 ABSTRACT

Emerging Megacities in East Asia face common challenges in responding to rapid population growth and there is an urgency to develop these cities in a more liveable and sustainable manner. Future Asian Megacities can play a key role in improving energy efficiency and addressing the effects of climate change through practical and pragmatic urban environmental planning measures. This contribution illuminates the way adaptation to climate change is tackled in spatial planning strategies. The possible impacts of climate change on mega-urban regions in South-East Asia are highlighting that spatial design and urban environmental planning are a promising tool in adapting to climate change, because its integral responses are capable in dealing with uncertainties.

Dealing with adaptation to climate change in the context of emerging Asian megacities requires a shift in policy options towards more proactive response strategies. While urban development trends in HCMC are addressing both mitigation needs and the rationale of adaptation to the effects of climate change, the main focus of combating climate change impacts in the mega-urban region of HCMC has to be the practical implementation of adaptation measures. Planned adaptation implies spatial planning decisions and measures at the urban-scale that facilitates the reduction of the adverse impacts of climate change. Further however adaptation has the potential to realise new opportunities for defining livability and sustainability in an Asian context of urban development planning, scoping planning issues and opportunities at different spatial scales.

2 ADAPTATION TO CLIMATE CHANGE IN VIETNAM

Vietnam has a long history of coping with natural disasters and mitigating their effects in many ways. However, the country must recognize that some impacts of global climate change are unavoidable, and as such there is an urgent need at present to start adapting the mega-urban regions to the current impacts of extreme weather events and the predicted impacts of climate change with which they are likely to be confronted in the future. With more than half of Vietnam's population now living in low elevation zones, coastal urban settlements are becoming increasingly vulnerable.

Recently climate change and its future impacts on Asian megacities in high-risk zones, such as the continent's main river delta regions, have emerged at the top of the international research agenda. Since then, international policy agreements have been established to limit the emission of greenhouse gases. Nevertheless, even if a reduction in these emissions is achieved, the time lag in the climatic system will inevitably cause a substantial degree of climate change. The impacts of this change are, however, uneven with inter-tropical, densely populated delta regions exposed to rising sea levels among those expected to be hardest hit. Here unprecedented cooperation and research is needed to identify the planning options available for adapting these regions to changing climate, advancing and disseminating knowledge and understanding. Spatial planning strategies which focus on the adaptation strategies to climate change require information regarding future changes at a scale relevant to the area under investigation.

2.1 Adaptation needs in the context of mega-urban regions in South-East-Asia

The overall objective of adaptation measures to reduce the future impacts of climate change is to assist the relevant authorities, in particular developing countries, including many of the least developed countries, firstly to improve their understanding and assessment of impacts, vulnerability and adaptation; and secondly to improve their ability to make informed decisions on practical adaptation actions and measures to respond to climate change on a sound scientific, technical and socio-economic basis, taking into account, of course, current and future climate change and variability. Adaptation tools are however only practical at the local level, in concrete spatial localities. For our research project a mega-urban approach is the main guiding element. Only at the urban level is it possible to integrate the many layers of site specific information and to work closely with the many administrative actors. The presence of a megacity enables the site specific

weighting of options, the integration of stake-holders and administrative institutions and the results and success of measures to be evaluated.

Table 1: Population Changes (2004-2009) in HCMC at district-level

Name of district	Area (km^2)	Population (Oct 1. 2004)	Population (Apr 1. 2009)	Population Difference 2004-2009	Population Density Difference 2004-2009(Inh./km^2)

3 URBAN DEVELOPMENT TRENDS IN HCMC

The spatial form of urban areas must be considered for adaptation planning. Asian cities, like HCMC, are getting more and more dispersed (see table 1), increasing their land areas without taking into account the natural conditions. This urban expansion processes are at the root of many urban hazards, especially urban floods. The later identification of risk areas and the resettlement of populations from these urban areas is a complex process which involves social, technical and financial questions not easily managed. As long as the current model of urbanization in Asian megacities continues to ignore the environmental constraints, no planned adaptation to climate change is possible. The current patterns of urban development, expansion and land use must be re-examined, because the generated dispersed urban forms (see figure 1) are reflections of processes which reproduce climate change related risks in new contexts, amplifying their intensity and increasing the numbers of vulnerable urban areas and population.

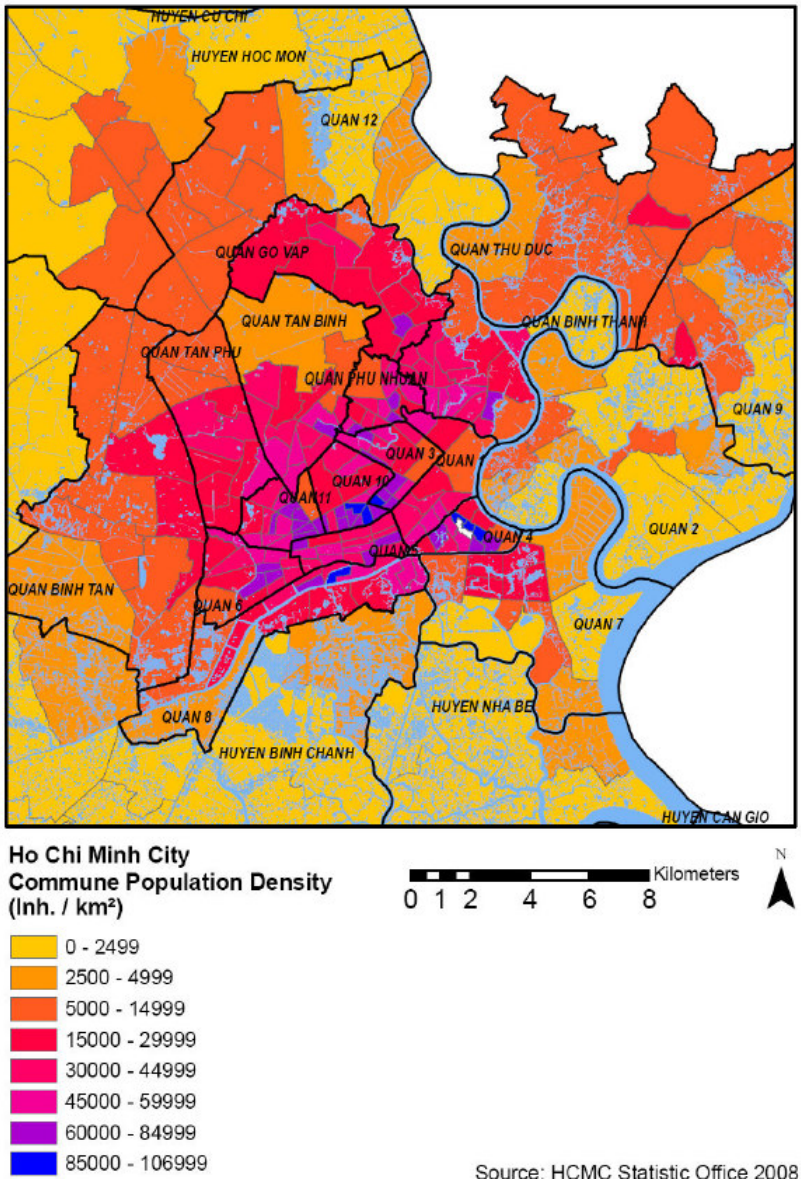

Figure 1: Ho Chi Minh City's Population Density in 2008 at Commune-level

Asian cities will play a specific role in adaptation research related to Climate Change. With population increasingly concentrated in urban spaces, and considering their dense nature and diverse urban forms and disrespect for the natural site conditions and climate phenomena, cities are among the spaces of greatest vulnerability to Climate Change. Ho Chi Minh City constitutes a hotspot where Climate Change related natural hazards are intensified, also congregating social and economic risks, whether or not they are produced at the urban scale. Emerging megacities, like HCMC, therefore, constitute a specific focus for adaptation measures guided by spatial planning science, since they are and will increasingly be the principal spaces of vulnerability.

4 SPATIAL PLANNING AND CLIMATE CHANGE

Climate change exhibits a strong influence on HCMC and its surrounding areas. Adaptation of the urban pattern and form, natural areas and the water system as well as housing and buildings is essential to protect HCMC from both the present and future impacts of climate change and extreme events to its complex system of physical, economic and social structures. Many of the components are interrelated, and therefore research needs to focus on the different scales evident in the mega-urban context (building, street block, neighbourhood, district, city, mega-urban conurbation) and their respective interaction. Due to the fact that investments in cities are long-term (sewage system, industrial areas, urban development projects, transport and water infrastructure etc.), finding the appropriate timing intervals in which action can be undertaken additionally plays an important role. These transitions in HCMC demand a careful organisation and

allocation of space, which is difficult not only to plan but also to manage. Therefore future climate scenarios, with all their associated uncertainties, must now be taken into account in development plans, urban design and environmental urban management concepts.

4.1 Adaptation tools for indicator-based decision-making in spatial planning

To gain insight into the effects of climate change on the urban level, such as the risk of flooding, heat stress in built up areas, a higher level of land subsidence and inadequate sewer capacity and to deal with them, the planning authorities of HCMC have the need to use spatially explicit information of climate effects highlighting which problems are to be found where, as well as diagrams of promising adaptation measures and projects. The indicator-based assessment approach we are taking calls for knowledge – and the dissemination of knowledge – to comprehend the consequences of climate related impacts on the urban area of HCMC. To draw up a well-considered climate adaptation strategy or to enable an assessment of its effects, certain tools to enable decision-making are needed. These include vulnerability assessment tools – which play a role particularly in policy preparatory work of spatial planning, such as urban development scenarios, spatially explicit assessment frameworks, such as risk and vulnerability assessment tools based on Strategic Environmental Assessment (SEA) for land-use planning– and evaluation tools that can be utilized at the implementation stage of concrete projects (planning studies, pilot project), such as monitoring and evaluation methods.

5 THE INTEGRATING CONCEPT OF “SPACE”

An adaptation of the mega-urban region of HCMC to climate change can only be achieved through the broad integration of urban and environmental planning approaches. The scale of the megacity itself presents the opportunity for sector-specific adaptation and mitigation approaches to combine into an integrative planning approach. As a result the central integration concept is `spatially referenced`. The concept ´space` allows the impacts of climate change on the megacity to be positioned on different spatial scales. Here spatial planning as a central strategy within our project can meaningfully combine individual approaches through the integrating concept of “space” as well as the embedment of the goal orientation of local stakeholders from administration and science. The spatiotemporal process of urban development, next to climate change, is the central dynamic element which enables spatially explicit scenarios. The integrative process of developing an Adaptation Planning Framework forms a comprehensive basis for implementing urban development adapted to climate change. For this, the broad inclusion in the administrative and political decision-making structures is necessary. An important contribution to the future political agenda for urban development in HCMC can thereby be made.

5.1 Administrative spatial planning framework

The most important agencies which determine overall land use, spatial zoning and environmental quality in HCMC are the Department of Natural Resources and Environment (DoNRE), the Department of Architecture and Planning (DPA) and the Department of Construction (DoC). Urban planning (in Vietnam, also referred to as urban development planning) is an essential tool for steering urban development processes and the spatial arrangement of land uses in HCMC. Theoretically, in Vietnam land-use and urban planning are a practical expression of socio-economic development strategies. In HCMC there are three master plans: the Socio-economic Development Plan, the Urban Development Plan (Master Plan) and the Land Use Plan. The Socio-economic Development Plan is designed to provide a context for the Urban development Plan and the Land Use Plan. Although these three plans differ in both their legal origins and their responsible administrative agencies, in principle they should share common targets for a coordinated and sustainable urban development. One important condition for the effective use of these urban environmental planning tools and guidelines is that they take into account the specific characteristics of climate change and adaptation policy. These include not only the inherent political character of planning processes in general, but also the long-term perspective, the uncertainties that arise and the dependence on other societal interests and developments. The planning administrations in HCMC require clear and unambiguous, spatially explicit and location-specific information that must be available and usable in the short-term. At the same time they are confronted with the need to draw up long-term spatial land-use and urban development plans with regard to climate change and are faced with major uncertainties of climate projections on the local level.

6 INDICATOR SYSTEM TO SUPPORT INTEGRATIVE URBAN LAND-USE PLANNING

The main objective of the proposed indicator system is to support the research project and the relevant administrative bodies in HCMC with indicator selection and the application of vulnerability and risk assessments in the context of impacts resulting from climate change and associated natural hazard impacts. The indicator system combines the challenge of theoretical conceptual improvement with the required integration of remote sensing and GIS techniques for both the monitoring and mapping of vulnerabilities and risk. The main tasks of the integrated indicator concept hereby are to: (1) assimilate existing vulnerability concepts from various scientific disciplines (e.g. flood management, urban climate assessment, urban energy security and transport planning); (2) apply indicators for spatially explicit vulnerability assessments for climate change and natural hazards; (3) apply and improve GIS-based quantitative approaches for analysing and modelling vulnerabilities and risks; (4) undertake complex spatially explicit vulnerability and risk assessments for the mega-urban region of HCMC based on advanced GIS techniques and the integration of remote sensing data for data management, data analysis and up- and downscaling in the framework of mapping vulnerability and risks.

6.1 Spatially explicit indicator system

According to the redefined role of urban environmental planning in times of climate change, spatial planning concerns the vulnerability assessment of space and place as a basis for action or intervention. Accepting this new task, spatial planning goes beyond traditional urban land use planning to bring together, draw upon and integrate policies for urban development and land use. The challenge of a changing climate influences both the nature of urban spaces and profoundly how they can function. Therefore, the integration of climate change adaptation planning into the spatial planning framework at the urban level is necessary. Here the main task of an indicator system is to capture the degree of integrated adaptation measures of spatial planning in a quantifiable manner. The development of the proposed indicator system has been guided by the following principles: (1) Indicators for adaptation planning in a spatial planning context need to be based on adaptation and mitigation objectives that can be derived from spatially explicit land-use and urban development plans, (2) These indicators must reflect spatial planning's contribution to the achievement of integrating specified key sector-specific adaptation and mitigation policies in the urban areas of HCMC.

Indicator sets can then be incorporated into a monitoring system that can assess spatial planning outcomes in terms of cross-sectoral adaptation and mitigation policy integration. A major consequence therefore is that the analysis of spatial adaptation plans will no longer solely focus on single indicator values, but increasingly on the combination of single base-indicators to yield meaningful policy measures, guiding adaptation and mitigation measures. Naturally, this type of analysis has to include the spatial dimension of the indicator system, by emphasising the importance of functional areas, spatial linkages and connections. Urban planners and key stakeholders can then utilise these plan-led indicators to revise their assumptions and core strategies that initially led to the policy actions. They will then be able to modify climate-related adaptation and energy-related mitigation policy in light of new issues identified. As a result the adaptation planning framework will help provide a communicative and iterative learning approach to monitoring, which will embed monitoring right in the centre of the policy-making process.

In our indicator system, single indicators are not intended for use in an isolated manner, but rather within an integrative framework which views them as parts of the resulting zoning guidelines in spatially explicit planning recommendation maps. Similarly, by using an Urban Structure Type approach the indicator system views individual locations as parts in a much wider spatial context rather than as isolated entities. This approach provides adequate flexibility to stretch the potential of obtained data to yield the necessary spatial information base, allowing effective monitoring of planning policy deliverables in combating adverse climate change impacts at the urban level.

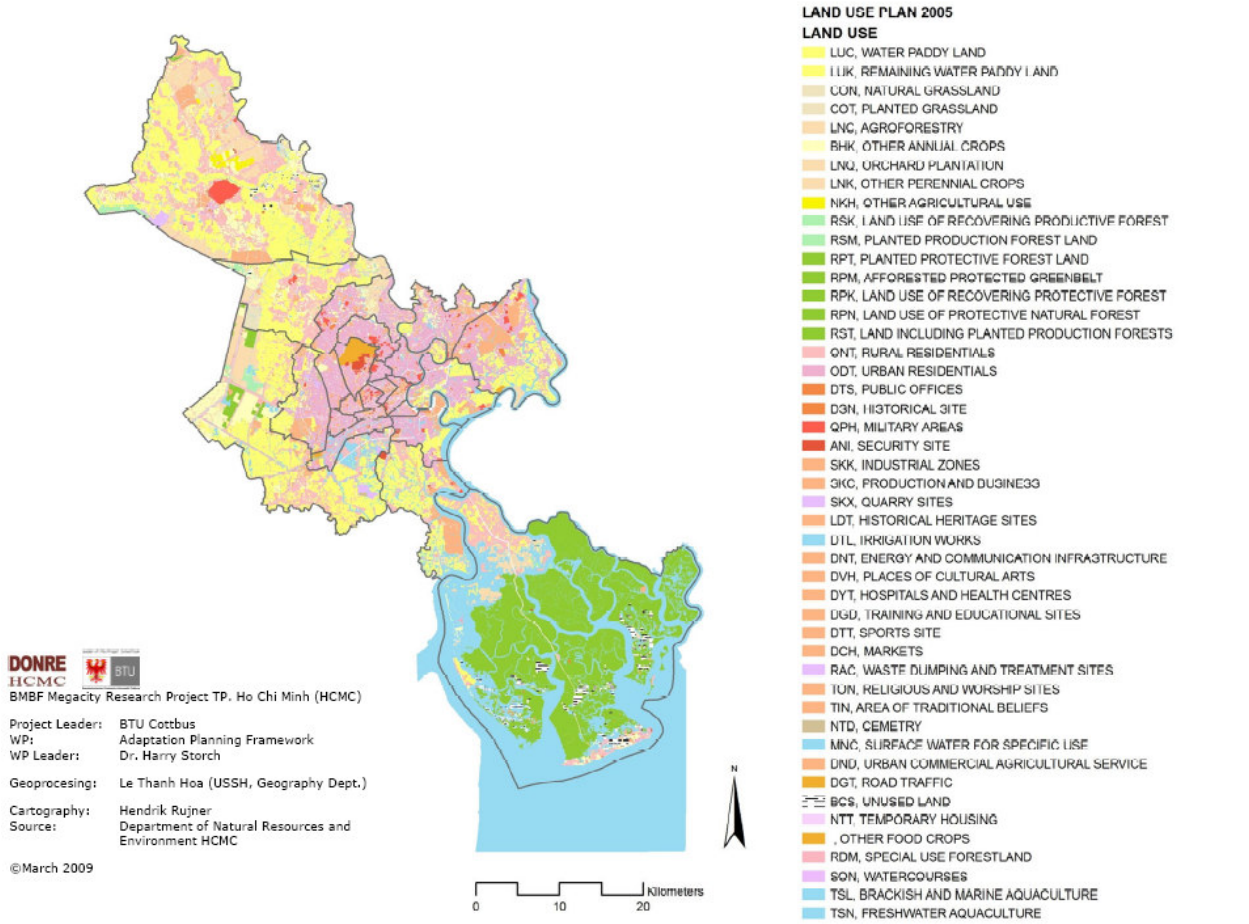

Figure 2: Land use map of HCMC as central component of the spatial information system

6.2 Spatial Urban Information System

Given the complexity of spatial policy implementation for adaptation and mitigation measures, the analytical and model-driven integration of base indicators is an essential tool for providing a more rounded view of different aspects of climate change policy. The emphasis is on developing a group of indicators within each thematic sector (Flooding, Climate, Energy and Transport) and collectively analysing them to understand the broader thematic spatial planning outcomes. This approach facilitates cross-cutting analysis by combining indicators across different thematic sectors, as well as including other more contextual sets of indicators.

If spatial planning activities involving indicator-driven spatial databases are not coordinated with the local administrative planning bodies, the indicator-specific data generated at various levels for urban planning and management purposes remains uncoordinated and limits their use to support decision making. In order to address these issues in a holistic manner, the central Spatial Urban Information System, developed from our specific GIS databases, will assist spatial planning decisions at the most relevant scales for the HCMC megaurban region. The Urban Information System will also be useful for assisting the modification and preparation of the upcoming versions of the Land Use Plan and the Urban Development Plan. Furthermore it can support more detailed urban planning schemes and serve as a decision-making support and strategic environmental assessment platform.

The Urban Spatial Information System has the key objective to meet the requirements of land-use, urban and environmental planning in the existing organisational and institutional environments of the administrative spatial planning departments of HCMC. The basic spatial data such as the base map, land use map and thematic maps generated can be utilised by various planning departments as well as for the further generation of derivative themes and sector-specific information.

7 TOOL FOR INTEGRATION INTO THE INSTITUTIONAL ENVIRONMENT FOR CLIMATE CHANGE RESPONSES

For the process of adaptation to climate change, land use planning is a key criterion for effective strategies to deal with the coming challenges. Adaptation is unattainable without improvements in the usability of scientific results for decision making and their integration into the existing planning process. Within the HCMC administration there is profound awareness in regards to the necessity of integrating environmental aspects, in particular the requirements from global climate change into the existing planning system. Nevertheless, the challenges of climatic change require a new level of cooperation to emerge between politics and administration, between the different sectors of administration and between academics, planners and decision makers in general. In order to identify possible starting points for the integration of climate change relevant planning requirements into the existing planning process, on the one hand, the organisation of the administration and governance structures within HCMC and the paths for decision making and on the other hand the problems concerning the integration of environmental requirements in the planning process, all these have to be analysed. To identify and estimate the local risks and adverse impacts arising from climate change, the project supports the HCMC administration to establish a well-founded data base with reliable information. The organisation of data access and the process of data exchange and dissemination between different sectors of the administration are important challenges in this context, not only in a technical sense but even more in the administrative respect. On the basis of such, data sets and maps with planning advice in reference to measures (restrictions, bans, conditions and development objectives) can be developed.

Some of the main spatial data for indicator base maps and land use maps will be obtained from remotely sensed sources, which will then be used for integration with the official land-use map using our Urban Structure Type approach. The focus of the indicator-driven Urban Spatial Information System is primarily to address the urban land-use planning and management functions. The data currently used has been collated from the respective urban administrative bodies and relevant departments, integrated into the GIS environment, and spatially geo-referenced. This data is then processed to derive spatial explicit ‘base indicator maps’.

7.1 Developing Planning Recommendation Maps: Goals and Problems

In further steps, domain specific GIS applications, analytical models and thematic assessment methods will be used to develop customised packages which in turn will generate sector-specific risk and vulnerability analyses in a spatially explicit manner. On the back of the obtained results from these procedures, so-called planning recommendation maps, an essential element for future urban planning and management will be generated. The overall aim here is the interlocking of the planning recommendation maps (multifunctionality of the landscape functions) or at the very least endeavour to consider the joint heighten significance of spatial areas, provided by the fact that many areas share a common requirement profile and should not only be individually represented in a plan. In this respect the same area may contain significant unsealed surfaces, or exhibit an infiltration, retention and or evaporation potential. In addition the same or adjacent area may also render itself suitable for preferential roof greening or for the development of retention water bodies or even for the protection of nature river banks.

The official HCMC Land Use Plan itself displays only the pure designation of land use utilisations. The inherent qualities i.e. environmental significance or the exposure or resilience of areas or structures, the urban structural densities or the real utilisation are not illustrated. For measures and planning recommendations maps, an initial differentiation between the restoration of the existing asset and the planning recommendations/guidelines for new designated areas has to be undertaken. Using the example from the Urban Climate and Urban Flooding viewpoint the focus here lies on recommendations and measures for the protection of Green- and Open Spaces and the establishment of more urban green in existing structures. Additionally the fundamental guidelines for new development sites i.e. regulations regarding building height, building density, and soil sealing degree will be suggested. For the thematic fields of Urban Climate and Urban Flooding, the formation of planning recommendation maps for the HCMC urban area arranges itself along the following considerations:

7.1.1 Reducing the surface runoff following extreme rainfall events.

Through the utilisation of the water household model ABIMO, in the framework of the research project, the mean surface water runoff can be investigated on the one hand due to the effects of climate change and on the other by the processes of urbanization. Hereby the additional problems associated with rainwater drainage will be seen. Planning recommendation maps are not specially localised, but inherently general suggesting increasing evaporation and where possible also infiltration by appropriate measures, i.e. rain water utilisation.

7.1.2 Protection of the Existing Forest and Green and Open Spaces

The protection is valid for all green and open spaces which are able to counteract or reduce the adverse effects of climate change for the urban area, i.e. are able to act as retention surfaces, urban-climatic functionally important areas etc. It is to be assumed that the Urban Climate investigations will validate their significance as local evaporation areas and temperature compensating areas/zones. Hereby, highlighting more precisely their interactions and specific importance and function to the surrounding settlements.

7.1.3 Planning of New Residential Developments with low flooding risk

The classification of development sites in areas which are at risk of flooding. In this context, in next working step of the project, the scientific justification and identification of such risk areas will be strengthened.

7.1.4 Enlargement of the Urban Green on the basis of urban climate considerations

This is the central goal of the work package Urban Climate. The main strategy is to improve the local urban ventilation patterns/ cold and fresh air generation zones and decrease the overall heat Island potential of the urban area. The designation of protection worthy zones in potential new development areas and within existing developments and the determination of small proportions of green areas for the entire greater regions should be implemented. Naturally a significant enlargement of the Urban Green will not be possible, since widespread demolition is not an option, but in light of the present situation in HCMC, the protection of these current areas is an asset. As widespread demolition is not an option, options include the potential “networking of green areas and “eco-belts” along the existing traffic arteries or the possible roof greening of existing structures. These measures could also lead to a reduction in the Urban Heat Island effect (and associated health impacts).

7.1.5 Classification/Designation of Retention Surfaces

On the one hand, the reservation of retention area (protected areas) for flood waters associated with Sea Level Rise or fluvial flooding events. While on the other hand, additional surfaces for the intermediate storage of rain waters must be identified and safeguarded for heavy rainfall events (rainwater retention functions).

7.1.6 Focus areas for measure to reduce surface runoff in existing area

Measures include unsealing, roof greening, rain water storage and –reuse. Whether it is however both possible and meaningful to locate these areas must be discussed (i.e. areas with high soil sealing rates, areas which are often flooded, areas where the existing canalization is inadequate). In the field of Urban Climate, a similar strategy is required, i.e. existing development on the basis of the “Thermal Load Map” are required to be defined and which are primary envisaged to be suitable for unsealing and greening.

8 OUTLOOK AND SUMMARY

In HCMC autonomous environmental planning for concretisation of the regional requirements is presently not recognizable. Therefore, the working results should be capable of fulfilling the needs for the new Master Plan in terms of transparency and professionalism. The process of joint development and discussion of planning bases will enable the administrative planning bodies to treat other aspects of environmental protection and the protection of natural resources in a similar way. Their interest in the approach of classification of protected areas and the determination of impact and priority areas or even “taboo areas” have an important role for the improvement of the the planning process. The consistent processing of spatial data from the database to the planning map is a substantial part of the knowledge transfer in the context of the project. Thereby an important role for cooperation arises in work-sharing groups of equitable scientists

and planners with a common obligatory objective. Via the cooperation of German and Vietnamese scientists from various universities on the one hand and different administrative bodies of HCMC on the other, the research project strengthens the willingness to cooperate for mutual benefit.

In regard to the administrative deficits, which exist in the administration of HCMC, large improvements are foreseen to result from this research project and by the incorporation of the Vietnamese partners. In the centre stands the consistent processing of reliable core indicators as planning information as well as their exchange between the different actors and the administrative bodies of development and environmental standards in spatial planning. Altogether a high demand for consulting exists, in regard to the development of environmentally referenced spatial data and their implementation into planning.

9 ACKNOWLEDGEMENT

The contribution is based on results of the research project 'Integrative Urban and Environmental Planning for Adaptation of Ho Chi Minh City to Climate Change' which is financed as part of the research programme 'Sustainable Development of the Megacities of Tomorrow' by the German Federal Ministry of Education and Research (BMBF).

1 ABSTRACT

In the last decade 3D city models received an increasing amount of attention from both, the scientific community and the professional field. One of the requirements for city models is that they should be maintainable, i.e., the system should be kept going and not be created for a specific decision and then abolished. What is the effect of such a requirement? Creating a model that represents the current status of a city is only problematic due to the vast amount of data to be collected and processed. Keeping the resulting model up-to-date, however, is more complex. This requires, for example, the introduction of 'time' as a concept in the model because then it can comprise the history and current status of the city as well as future development scenarios. The processes that lead to changes in the city must thus be represented in the city model to allow the changes. In the paper we discuss these problems and show necessary properties for city models and systems maintaining them to reach a reasonable level of maintainability.

2 INTRODUCTION

Digital city models are an important topic in current research. Topics include automatic building detection (Brenner 2000; Früh and Zakhor 2003) or sub-surface infrastructure (Forkert 2006). Applications of 3D city models include noise modelling (Kurakula and Kuffer 2008). Cities like Berlin (www.3d-stadtmodell-berlin.de/3d/seite0.jsp) or Vienna

(www.wien.gv.at/stadtentwicklung/stadtvermessung/geodaten/stadt¬modell/produkt.html) invest large amounts of money to create such models. Applications must then create enough revenue to justify these expenses. However, cities change constantly and thus the models will be outdated one day. There are two different scenarios to counter this problem:

- 1.The revenue from the applications is large enough to reach the break-even point before the model is outdated. Then again money can be invested to create a new model.
- 2.The model is constantly updated and can thus be used over an extended period. Revenues from applications will then pay for the updates and any profit provides down-payments for the investment.

The remainder of the paper is structured as follows: We start with some definitions to avoid misunderstandings. Then we briefly discuss the different quality levels that have been defined for city models and observation processes suited to collect data for these levels. We then show typical applications where city models are used. These applications demand specific levels of quality from the city models. The next section discusses changes in a city that need to be captured to keep the model up-to-date. Finally, we discuss possible update processes for each quality level and relate it to the applications. Some conclusions finish the paper.

3 DEFINITIONS

Several definitions are necessary as a starting point. We discuss maintainability of city models. Thus we have to explain what we mean by maintainability and city models. A term frequently used when discussing spatial decisions and city models is sustainability. We show how this concept is typically used and argue why this should not be used for the questions addressed in this paper.

3.1 Models of Cities

Models of cities can mean different things. It may be a model of the interactions within a city or a model of topographic relations between objects in cities. We use the second type of city models. Many objects in cities can only be reasonably well described in three dimensions and thus city models are often 3D models. A standard frequently used for structuring the data is CityGML (Kolbe and Bacharach 2006).

3.2 Sustainability

The definitions of sustainability are manifold. It is said, for example, that it "relates to the maintenance or improvement of the integrated natural systems that collectively comprise life on our planet" (Egger 2006, p. 1236) or that it "is related to the life and more specifically to the survival of all beings and humans in the environment" (Mitoula and Economou 2007). Sustainable urban development can then be seen in the context of "environmental stewardship, inter-generational equity, social justice, and geographical equity" (Haughton 1997, p. 189). The goal is typically ecological sustainability (Bandyopadhyay, Bandyopadhyay et al. 2009; Cerreta and Salzano 2009; Mahmoudi and Fanaei 2009) but also economical and social sustainability are discussed (Ostermann and Timpf 2007; Meir 2009; Ostermann 2009). These three kinds of sustainability have been defined in the Agenda 21 (United Nations 1992). These definitions extend the meaning of the term sustainability to cover different kinds of impacts. This is crucial when discussing city development. In this paper we discuss digital city models that serve as data basis for decision making. Above definitions complicate the discussion for the kind of application addressed in this paper and impede the concentration on the core technical problems for digital city models. A completely different definition can be found in the Brundtland report, which defines sustainable development as "development that meets the needs of the present without compromising the ability of future generations to meet their own needs" (Brundtland, Khalid et al. 1987, p. 24) but this is even more difficult to translate to technical issues of 3D city models.

3.3 Maintainability

"To uphold as valid, just, or correct" is another definition of sustainabiliy (Nichols 2001). This is a perfect definition for the purpose of this paper. It is, however, not a typical definition in spatial planning. Thus talking of sustainable models could lead readers to wrong conclusions about the content. We thus decided to use the term maintainability for the fact that the model should be used during an extended period for multiple decisions and applications. The model must then be adapted whenever the city itself is significantly changed. The significance of a change depends on the application.

4 QUALITY CLASSES OF 3D CITY MODELS AND HOW TO OBTAIN THE DATA

CityGML defines five different quality levels for city models (Kolbe, Gröger et al. 2005):

- Level of detail 0 (LoD0): digital terrain model (DTM) + aerial image
- Level of detail 1 (LoD1): Block models of buildings
- Level of detail 2 (LoD2): Roof structures, textures
- Level of detail 3 (LoD3): Detailed roof and wall structures including balconies and vegetation
- Level of detail 4 (LoD4): Interior structures like rooms, doors, stairs, and furniture

These levels of detail require different types of data collection. Models with LoD0 to LoD2 can be produced automatically from aerial images whereas interior structures, for example, depend on the availability of either detailed surveys or architectural documents. Table 1 shows the level of detail needed for different applications.

Aerial photogrammetry can provide information on 3D geometry (height of terrain and buildings, footprints of buildings, and roof structure) and ground texture. It is difficult to get texture for vertical walls from aerial photogrammetry because of the wall's distortion in the image. Aerial images have been used to provide texture because it is cheaper and sometimes no other sources are available (see, for example, Steidler and Beck 2005). However, aerial images do not lead to high resolution textures. When creating views from a pedestrian perspective then the texture must be applied in resolutions which can be provided only by terrestrial photography (Göbel and Freiwald 2008). Thus many projects use terrestrial images for texturing the objects (Holzer and Forkert 2004; Poesch, Schildwächter et al. 2004).

Airborne laser scanning (ALS) can provide more accurate geometrical data. ALS data have been successfully used for automatic detection and modelling of buildings (Rottensteiner 2003). ALS data contain no information about the texture. However, they may be used to detect vegetation since the different reflection characteristics allow a classification (compare, for example, Maier and Hollaus 2008).

Terrestrial surveys can provide all necessary data but the costs are higher than those of airborne methods. Thus methods like car-mounted fisheye cameras have been adopted to reduce the costs (e.g., Forkert, Haring et al. 2005). Still, these methods are expensive and can only provide data for LoD2 (textures) and LoD3 (façade details). Interior structures still require classical surveys using, for example, laser scanners. However, available architectural maps can provide some information as shown in the case of the Vienna underground modelling (Forkert 2006).

5 USAGE OF 3D CITY MODELS

3D city models have usage in various domains, e.g., urban planning and management, noise and air pollution, disaster management, tourism, facility management and environmental management simulations, homeland security, real estate management, vehicle and pedestrian navigation, and training simulators etc. A rough categorization of tasks in spatial planning includes (Navratil 2006)

- planning for future development,
- planning for dealing with a specific situation where planners propose solutions and a discussion leads to a decision, and
- planning for dealing with a specific situation where the affected agents (lay people) develop a solution.

The three kinds of tasks have different demands for the quality of 3D city models. The planning of future development requires a complete inventory of relevant objects. Precise information on colour, patterns, or shape is not necessary. The presentation of a specific solution to a wide audience, however, is typically done with virtual reality. Then not only the completeness of the inventory is important, but also the detailed graphical representation. In the following paragraphs we give a brief account of the usage of 3D city models for urban planning, disaster management, and noise and air pollution.

Virtual 3D city models enable urban planers to visualize the existing city state, and take decisions for future developments accordingly. The development plans can be simulated before execution, thus enabling intelligent decision making. The possible data sources for a 3D city model are cadastral data, digital terrain models, building models, street-space models and green space models (Döllner, Kolbe et al. 2006). Urban planning is a complex task involving the interplay between multiple aspects of a city, e.g., transport, pollution, and crime. Hamilton, Wang et al. (2005) introduced the concept of nD urban model that provides a holistic view of the city by integrating diverse data sources like 2D maps, 3D urban models, thematic information, historical data, national statistics, local survey, and various policy and regulations.

3D city models are tools for rescue operations during disasters, e.g., flooding, earthquake, and fire, etc. The disaster situations can even be simulated so as to train rescue operators and even preplan the strategies to tackle emergency situations, e.g., location of damaged site, indoor and outdoor navigation for helpers, and determining escape route for affected people from effected site or building (Kolbe, Gröger et al. 2005).

With the growing population in urban areas, there is a dire need to address the issue of noise pollution. The major source of noise is the traffic noise and affects the inhabitants along road sides mostly. In order to mitigate the effects of noise pollution, 3D noise maps in combination with 3D city models are used (Kurakula and Kuffer 2008). Since noise propagation depends on topography, building structures and other structures (trees etc), 3D city models help the decision makers to envisage the intensity, propagation patterns of the noise in cities and take appropriate actions. The data required for noise modeling include road networks, noise sources (traffic information, construction sites, industries etc.), buildings (residential, schools, offices, hospitals etc.), population (inhabitants) and green areas (parks), etc.

3D city models are important tools to visualize and simulate air pollution levels. The pollutants carried by the wind may be trapped in the high building structures and street canyons thus causing high pollution in such areas. One of the dominant sources of air pollution is the traffic pollution. Information about traffic air pollution and distribution of pollutants is therefore important for taking effective decisions for air quality improvement and future urban designs (Wang, van den Bosch et al. 2008). The data sources include pollution sources (vehicles, industry etc), wind data (speed, direction etc.), surface temperature, street canyon geometry (Métral, Falquet et al. 2009), and the shape of buildings etc.

Application Area	Model LOD
Urban Planning	LOD0-LOD3
Noise Pollution	LOD1-LOD3
Disaster Management	LOD3, LOD4
Traffic Management	LOD1
Air pollution	LOD0-LOD3

Table 1: Model LoD for different applications

6 CHANGES IN CITIES

Cities are changing constantly. There are two categories of changes:

- Constant changes, e.g., replacement of a building, construction of a new road, etc.
- Temporal changes, e.g., snow on the streets, trenches along streets to install supply lines, etc.

Typically, only the first kind of change is important for 3D city models. Temporal changes are only necessary for analysis of situations that are affected by the change. Traffic guidance, for example, may be influenced by road construction work because roads are blocked. Such tasks are usually not solved by 3D city models but they may become relevant, e.g., in disaster management. However, such information could be integrated in the application from outside sources and need not be stored in the city model itself. They would not be relevant for the city model itself.

Constant changes may influence different aspects of a 3D city model:

- Creation, change, or destruction of a single object: Examples are the creation of a new building or road, the change of a building façade, the replacement of an old bridge, or the clearance of an old gas station.
- Changing objects in a specific area: The construction of a new road is an example for a situation where above actions are performed on a number of different objects: fences are relocated, traffic signs placed, and trees cut down.

The first type of change has been modelled for database objects (Medak 2001). It not only applies to large changes like the reconstruction of parts of a building since applications may also be sensitive to small changes like repainting a façade. The second type of change comprises a set of changes of the first type. Thus the mechanisms shown by Medak also apply to this case.

All of above examples occur at a specific point in thime. Thus they have a date attached to them. This date may be fuzzy like in ‘the building was created in the years 2007 to 2009’ but it exists. This is not the case for natural changes like deterioration either by environmental influences on the object or use of the object. Roads with high traffic loads, for example, will show wear and colours on façades change over time. These changes do not fit in Medak’s system. However, they may be important for some decisions. Visualizing the existing city state must include the deterioration because otherwise the city planners will come to wrong conclusions. Although inspection of the city area in discussion will clearly show the difference, problematic areas might be missed when only using the digital model. In order to eliminate this problem other tools will have to be used. This somewhat lessens the benefits of the model itself for city planning because it is only one of a few tools.

7 UPDATE OF 3D CITY MODELS

What does the above mean for 3D city models? Objects in the model must be changed if the original changes. The challenge is finding all changes in the city.

7.1 Level of Detail 0

The DTM will only change either due to natural disasters like earthquakes, land slides, or volcanic activities or due to massive earth movement on construction sites. Natural disasters typically cause a large amount of destruction and thus imply dramatic changes. Thus a reconstruction of the affected area will be necessary. Constructions are more difficult to be detected. It may be, however, that constructions with sufficient change

of the terrain must be announced. Then the information about the existence of changes is available and only the effects have to be determined.

7.2 Level of Detail 1

For block models most of the changes discussed in section 6 are irrelevant. The only important changes are

- the creation of new buildings,
- the destruction of buildings, and
- a massive change of a building shape.

Again, if these kinds of changes must be announced, the information about the change is available. Otherwise the detection is tricky. Current approaches use the creation of new models and the comparison of the old set of blocks with the new set of blocks. Although the interpretation of the survey data (e.g., GPS tracks or ALS data sets) can be done automatically to a large degree, there is still some effort necessary to classify the deviations. In addition, the surveys themselves are costly and thus performing them without reasonable suspicion that there are changes is questionable.

7.3 Level of Detail 2

LoD2 requires roof modelling in addition to the building outlines. Roofs can be modelled, e.g., by aerial photogrammetry (e.g., Frere, Hendrickx et al. 1997), ALS (e.g., Haala and Brenner 1997), or a combination of both (e.g., Rottensteiner and Briese 2003, Jaw and Cheng 2008). LoD2 only contains the general shape of the roof. The roof of a simple, rectangular building then typically consists of two planes. These can be detected with a high degree of automatization. In this case the main costs for the roof detection emerge from the ALS-flight itself. The situation may be more difficult in old city centres with different and very specific roof structures but results for Vienna (Rottensteiner and Briese 2003) suggest that a combination of ALS and aerial photogrammetry may solve the quality problem. It is questionable, however, if these processes can be fully automated and work without human supervision.

Single roofs can also be determined from other data sets like construction drawings, terrestrial laser scanning, terrestrial photogrammetry, or classical, terrestrial survey at lower costs than by ALS. It is necessary, however, to know which roofs have been changed to adapt these methods. This is simple if changes have to be announced but if this is not done then ALS or aerial photogrammetry seems to be the only method to update the city model. The problem is then reduced to finding significant differences between the roof models.

Textures are also available in LoD2 models. As discussed in section 4 these are difficult to collect because airborne methods currently do not produce textures with the required quality. The texture of the façade may be relevant for different kinds of application. Visualization of urban planning projects may depend heavily on the state of the surrounding façades. Thus current images of façades may be relevant for decisions. Announced changes of façades can be easily tracked. Unannounced changes, however, provide the same problem as the roof structures: Complete resurvey would be necessary to detect all changes and this resurvey is expensive.

7.4 Level of Detail 3

What has been said about the roofs in LoD2 is also true for the detailed root structures in LoD3. The only difference is the detail of the survey and the degree of interpretation. A more detailed survey with ALS may require lower flight height and thus a straight path covers a smaller strip of land. More flight time is then necessary to cover the area of a city. This increases the cost of data collection. Since more data are produced (the amount of data produced by ALS depend on the scan frequency and the scan duration), more effort is necessary to interpret the data. Detailed roof models consist of more parts than the simple ones used in LoD2. Thus both, the interpretation of the ALS data and the change detection are more difficult: Does the difference between the models reflect an actual change or is it based on the specifications of the equipment and interpretation algorithms used? If the difference is based on the equipment, which of the two models is the ‘correct’ one? These questions may be difficult to determine and may require on-site inspection.

Wall structures present another challenge. Some structures may not be visible from above, e.g., a small balcony below a large one. Thus methods like terrestrial photogrammetry or terrestrial laser scanning are necessary to capture the data. Both methods are expensive and periodic application is not feasible.

The collection of vegetation can be done by aerial photogrammetry or ALS. Vegetation is influenced heavily by both types of changes discussed in section 6. Growth models for vegetation and different kinds of rendering algorithms may help determine the natural changes like seasons or growth. This is more difficult for changes by human intervention. The human intervention may aim at keeping vegetation in a specific shape like it is, for example, the case in the garden of castle Schönbrunn. In this case the hedges are kept in a specific shape. City models can ignore these kinds of interventions because they keep the city model up-to-date. The same cannot be said about interventions that are necessary for other reasons like surrogate plantation for trees that had to be cut during construction works. Again missing documentation leads to high costs.

7.5 Level of Detail 4

Adding interior structures like rooms, doors, stairs, and furniture is extremely expensive. Airborne methods cannot provide these data. The only methods are evaluation of existing construction documentation or specific surveys. The use of existing documentation is cheaper, especially if the documentation is available in digital form. However, old buildings typically only have such documentation if they are of public interest (town halls, airports, school, etc.) and these are only a minority within a city. Thus comprehensive city models with LoD4 are not realistic. The data is extremely expensive and the only application for it seems to be disaster management. In detail this is only necessary for crowded buildings. As soon as the people are led out of the buildings then the interior structure is irrelevant. Thus LoD4 is only necessary for the first step during disaster management and this is typically only done in a structured and organized way for public buildings.

8 CONCLUSIONS

We showed that higher levels of detail affect the process of keeping the city model up-to-date. Maintaining a model with LoD0 can be done almost automatically, whereas in theory a model with LoD4 would require an update whenever an apartment is refurnished. This is not feasible. The challenges are

- receiving information about the change and
- assessing the significance of a change.

The main problem is thus the data collection and not the data modelling. Efficient strategies are necessary to acquire all data necessary to keep the model up-to-data. These data can be acquired either for the whole city at once in regular intervals or continuously as the reality changes. In both cases the process must be cost effective. This typically calls for a high degree of automatization or automatic communication from the initiator of the change. There are three possible solutions:

- Keep the 3D city models simple: Models with only blocks for buildings or even with detailed roof models can be automatically updated as long as the data can be generated automatically from sources like aerial photographs, satellite images, and ALS.
- Allow different levels of detail for different parts of the city: Important historic buildings could be modelled with higher level of detail than other parts of the city. It is then necessary to assess the benefits added to the model by these additions. Different levels of detail may be problematic for some tasks that shall be supported by the city model. Judging architectural design, for example, calls for a model with detailed façade textures and vegetation, which is level of detail 3. If parts of the city model only have level of detail 2 or lower then this process cannot be supported throughout the city. How to communicate the level of detail is thus an important question in the design phase.
- Install processes that force citizens to provide data for significant changes: Compulsory building permits, for example, show where new buildings are planned and may also provide detailed 3D geometric data on the building. This would eliminate the need for surveys detecting changes. However, such changes of processes should not be implemented too frequently because they change the way public administration works and public administration should be stable.

Recent developments in data capture include crowd sourcing or volunteered geographic information (Goodchild 2008). It is not yet clear how this method can be used to collect large data sets. First experiences, e.g., with OpenStreetMap, look promising and may be adapted to detect changes in cities that need to be included in city models.

1 ABSTRACT

Eine Frage beschäftigt die Planung seit jeher: Wann ist die Stadt lebenswert? Mit welchen neuen, computergestützten Methoden kann die stadtplanerischen Diskussion eine neue Qualität erhalten? Monitoringsysteme, gespeist mit individuellen Daten verschiedener Benutzergruppen können hierbei in einem neuen bottom-up Planungsverständnis wertvolle Erkenntnisse liefern. Die Idee hinter dieser Aufgabenstellung ist, ähnlich wie es Kevin Lynch mit seinen Mental Maps praktizierte [Lynch 1960], den stadtplanerischen Horizont zu erweitern und ihn zusätzlich mittels neuer Geowebtechnologien einer digitalen Renaissance zu unterziehen. Am Beispiel der Stadt Kaiserslautern werden die Bewegungsmuster von Probanden in der Stadt Kaiserslautern über einen längeren Zeitraum getrackt, über diese „Tracking People Methode“ mit Menschen als Messfühlern untersucht. Datengrundlagen sind OSM-, Google Earth-und GPS-Daten, die zusätzlich über sogenannte „Walking Diaries“ validiert werden. Alle Daten werden anschließend aggregiert, so dass städtische Dichtekarten von bevorzugten Wegen und Aufenthaltsorten der Testgruppe entstehen. Mit diesen Karten können Hotspots, aber auch ungenutzte Bereiche in der Stadt identifiziert werden, die eine neue Sichtweise auf die Nutzung städtischen Infrastruktur zulassen. Zusätzlich können durch diese Informationen dem Planer neue inhaltliche Analysemöglichkeiten eröffnet werden, welche dieser im urbanen Planungsprozess gewinnbringend einsetzen kann.

2 THEORETISCHE GRUNDLAGEN

Lebenswerte, gesunde und prosperierende Städte sind ein erstrebenswertes Ziel für die Stadtplanung sowie auch für deren Bürger. Doch bevor Maßnahmen getätigt werden um diese Vision zu erreichen, stellt sich die Frage: Wann überhaupt ist eine Stadt lebenswert und ist es möglich, darüber quantifizierbare und validierbare Aussagen zu treffen? Neben den klassischen Standortfaktoren gewinnen die weichen zunehmend an Bedeutung und werden immer mehr zum ausschlaggebenden Faktor, wenn es darum geht Standortentscheidungen zu treffen – sei es für Unternehmen als Standort für den Firmensitz oder auch als Lebens- und Arbeitsmittelpunkt für den einfachen Bürger. Dieser Aspekt wurde unter anderem auch schon von Richard Florida untersucht, welcher in diesem Kontext erläuterte, dass sich das ehemalige Prinzip „People follow Jobs“ sich umgekehrt hat und heutzutage attraktive und lebenswerte Städte mit einem gutem Image und einer kulturellen Vielfalt – entstanden durch die dort lebenden Menschen – die sog. „kreative Klasse“ und damit auch Arbeitsplätze anziehen [Florida 2004]. Dreh- und Angelpunkt dieser Betrachtung ist der Faktor „Mensch“. Doch wie kann eben dieser methodisch als Messfühler für planungsrelevante Fragestellungen eingesetzt werden? „Normale“, konventionelle und quantifizierbare Werte, wie etwa Baulandpreise, Bodenrichtwerte oder Lärmmessungen werden schon seit langer Zeit in der Stadtplanung verwendet. Wie jedoch können komplexere und subjektive Daten erfasst und kartografiert werden, damit deren weitergehende Nutzung und Analyse und schließlich deren fachliche Nutzbarmachung möglich ist? Lassen sich z.B. Mental Maps im Sinne von Kevin Lynch verorten, so dass diese für die stadtplanerische Diskussion nutzbar sind? Hierbei stellt sich die Frage, wie Methoden für der Datenerfassung und Behandlung aussehen können und welche speziellen Fragestellungen und Probleme zu beachten sind und welche Anforderungen das Arbeiten mit dem Menschen als Messfühler verlangt. Ergänzend wird auch die Frage nach der Konzeption einer adäquaten Visualisierung dieser komplexen Fragestellung behandelt.

Insbesondere mobile Anwendungen auf mobilen Endgeräten befeuern diesen Trend zunehmend und liefern wichtige Innovationsideen und -methoden, denn räumlich verortete Informationen und Dienste wie Location Based Services (LBS) sowie vor allem auch die daraus generierten Inhalte erlangen zunehmend Relevanz. Deshalb ist es nicht verwunderlich, dass die Koppelung von GIS- und GPS-Systemen zunehmend im Fokus

des planerischen Interesses steht. Mental Maps können dementsprechend aufgewertet werden, in dem Probanden mithilfe der GPS-Technik „in stadträumlichen Umgebungen durch digitale Systeme gewissermaßen eine Art zweites ‚Erinnerungs-Bild" extrahieren können [Streich 2005:308]

Einige Projekte, wie zum Beispiel die „Regionsidentifizierung" in „1,2,.. Scheibenhardt" [Berchtold et al. 2002:44ff], das Projekt „emomap Mannheim"[vgl. hierzu Zeile et al. 2009] oder die „GPS-Studie Studentenstadt Karlsruhe" [Berchtold et al. 2009] liefern erste Anhaltspunkte darüber, wie „Tracking" des Messfühlers „Mensch" als mögliche Methode für planerische Aufgaben eingesetzt werden kann: Wurde bei der ersten Arbeit von Berchtold et al. noch die Aufzeichnung der Wege dafür benutzt, um die Region Karlsruhe durch ihre Bewohner in ihrer ganzen Vielfalt zu beschreiben und um Hauptattraktoren zu identifizieren, so bedienen sich die neueren Arbeiten schon der GPS-Technik zur Aufzeichnung der Wege. Einmal verbunden sogar mit der Verknüpfung von physiologischen Daten zur Identifizierung von emotionalen Hotspots [vgl. Zeile et al.] zum anderen wurden bei der „GPS-Studie Studentenstadt Karlsruhe" 100 Probanden mithilfe eines GPS-Trackers und eines digitalen Routenbuches über einen Zeitraum von vier Wochen in Karlsruhe beobachtet.

3 DAS EXPERIMENT „TRACKING PEOPLE"

Im Rahmen von zwei studentischen Projekten wurde als Untersuchungsfeld die Mobilität der Studierenden in Kaiserslautern ausgewählt. Während bei dem vorangehenden Forschungsprojekt Emomap [vgl. Zeile et. al. 2009] sich der Fokus auf eine Verknüpfung von physiologischen „Befindlichkeiten" sowie der Wegemuster bezog, wurde bei dieser Projektarbeit mittels des Trackings der Probanden deren Wege- und Aktivitätsmuster erhoben. Durchgeführt wurde das Experiment in zwei Untersuchungsreihen: Die erste über den Zeitraum von zwei Wochen im Mai 2009 sowie eine vierwöchige zweite Phase im Dezember 2009.

3.1 Methodik

Die Methode des Tracking umfasst drei wesentliche Arbeitsschritte: Zum einen die Aufnahme der Daten aller Probanden über ein sogenanntes „Walking Diary" – eine Art Tagebuch – das die einzelnen Wege und Punkte sowie deren Zweck mittels Google Earth dokumentiert. Zum anderen die GIS-gestützte Aggregation der Daten aller Teilnehmer und drittens die Abfrage und Auswertung dieser Daten. Für alle Aktionen wurde ein vordefinierter Katalog mit 22 Attributen und eindeutiger Nomenklatur erstellt, um verschiedene Schreibweisen und Fehlinterpretationen auszuschließen.

Im Walking Diary müssen die Probanden ihre Wege nach Datum, der Uhrzeit mit Beginn und Ende der Strecke, sowie den Start- und Endpunkt des Weges mithilfe der „Strecke zeichnen"-Funktion erfassen. Zusätzlich sind die Attribute wie „Zweck des Weges", „Verkehrsmittelwahl" sowie das „Geschlecht" und eine eindeutige, anonymisierte „ID" der Probanden mit aufzunehmen. Da nicht nur die Bewegung wichtig ist, sondern auch die Verweildauer vor Ort, müssen zusätzlich über die „Placemark setzen"-Funktion in Google Earth die Aufenthaltsorte erfasst werden. Diese sind wiederum nach Datum „Ankunft", „Abreise", „Ort", „Zweck" und „ID" und „Geschlecht" zu sortieren. Zusätzlich können an einem Aufenthaltsort auch sogenannte „Statuswechsel" erfolgen, wenn zum Beispiel der Proband von „Freizeit" auf „Schlafen" wechselt. Die Punkte und Wege werden in Google Earth mit einem Datumsstempel versehen, und in Ordner zum jeweiligen Tag archiviert und gespeichert. Das Aufzeichnen des Diaries geschieht über eine Tabelle, die über den jeweiligen Datums- und Uhrzeitenstempel mit den jeweiligen Geodaten der Wege und Aufenthaltspunkte in einem GIS-System verknüpft werden. Danach ist es möglich, verschiedene raumrelevante Abfragen mit den erfassten Attributen zu tätigen. Beispielhaft sind die Wege aller Probanden als Dichtekarte oder das geschlechtsspezifische Einkaufsverhalten zu nennen. Alle daten wurden mithilfe eines GIS-Systems aggregiert und analysiert.

3.2 Auswertungsergebnisse

Die Auswertung der Projektarbeit sollte anhand thematischer Schwerpunkte geschehen, zu denen die Studenten ihre getroffenen Annahmen anhand der Datensätze in Bezug auf ihre Validierbarkeit überprüfen. Hierbei wurden Untersuchungsfelder gewählt, wie etwa verkehrstechnische Betrachtungen bezüglich des Modal Splits (hier wurde z.B. für die Probanden die Feststellung gemacht, dass v.a. die pendelnden Studenten sich vorwiegend mit dem Auto in der Stadt fortbewegen, während die Wohnhaften überwiegend zu Fuß gehen oder mit dem Fahrrad fahren), vielfach aufgesuchte Bereiche (beliebte Punkte für Einkaufen,

Weggehen etc.) oder etwa die Verteilung der Orte des Lernens an der Universität. Folgende exemplarische Beispiele verdeutlichen die gemachten Beobachtungen:

3.2.1 Einkaufsverhalten

Die folgende Abbildung zeigt das Einkaufsverhalten der Studenten in der Innenstadt von Kaiserslautern. Der grün unterlegte Bereich wurde anhand einer Dichtemessung generiert und zeigt den Hauptaktivitätsbereich der Probanden. Die Haupteinkaufsort wurden zudem mit punktuellen Symbolen verortet. Als Feststellung wurde beobachtet, dass die weiblichen Probanden (rote Symbole) sich vorwiegend im Bereich der Innenstadt in einer Straße mit einer Vielzahl von Textileinzelhandelsgewerbe aufhielten, während die männlichen Probanden diesen Bereich nahezu komplett zum Einkaufen mieden und vorwiegend Güter des täglichen Bedarfes in anderen Bereichen der Innenstadt nutzten.

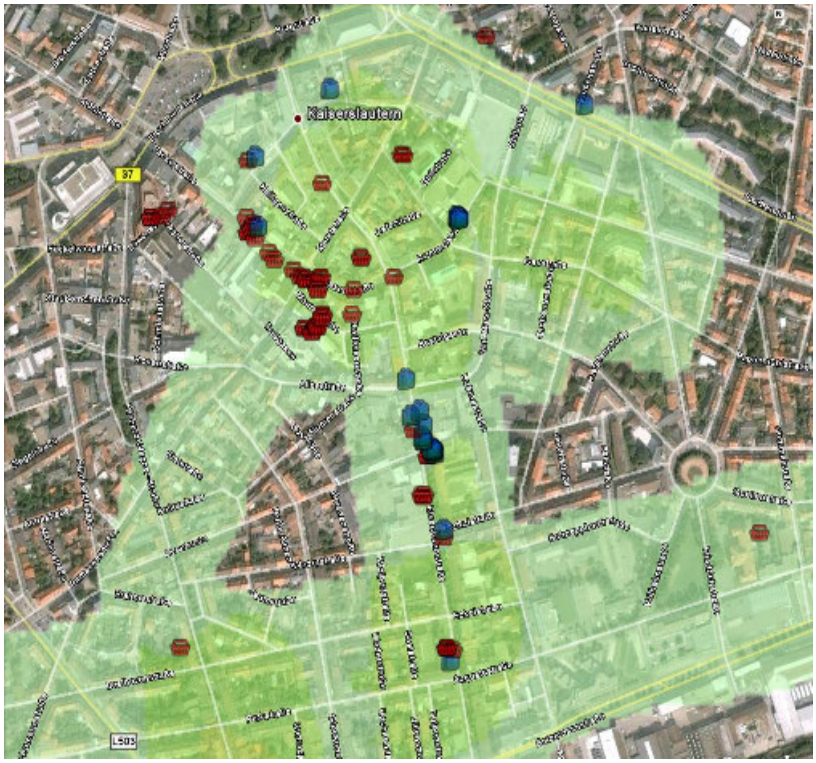

Fig. 1: Unterscheidung Einkaufsverhalten der männlichen (blau) und weiblichen Probanden (rot), Analyse Probanden Braun, Ohnesorg & Schaaf [CPE 2010]

3.2.2 Zweckgebundene Aufenthalte an der Universität

Die Vorgabe sah keine ausschließlich flächige Verortung der erhobenen Daten vor, auch eine Visualisierung mittels Google Earth und verorteten Balkendiagramme war möglich. Bei der folgenden Grafik ist die unterschiedliche Aufenthaltsdauer der Studenten je Zweck an der TU Kaiserslautern zu sehen. Auffällig ist hier beispielweise der gelbe Ausreißer in einem der Hauptgebäude der Universität, an welchem eine Party auf der Universität stattfand und die Studenten großteils dort eine lange Aufenthaltszeit hatten, sich sonst aber eher selten in dem Gebäude aufhielten.

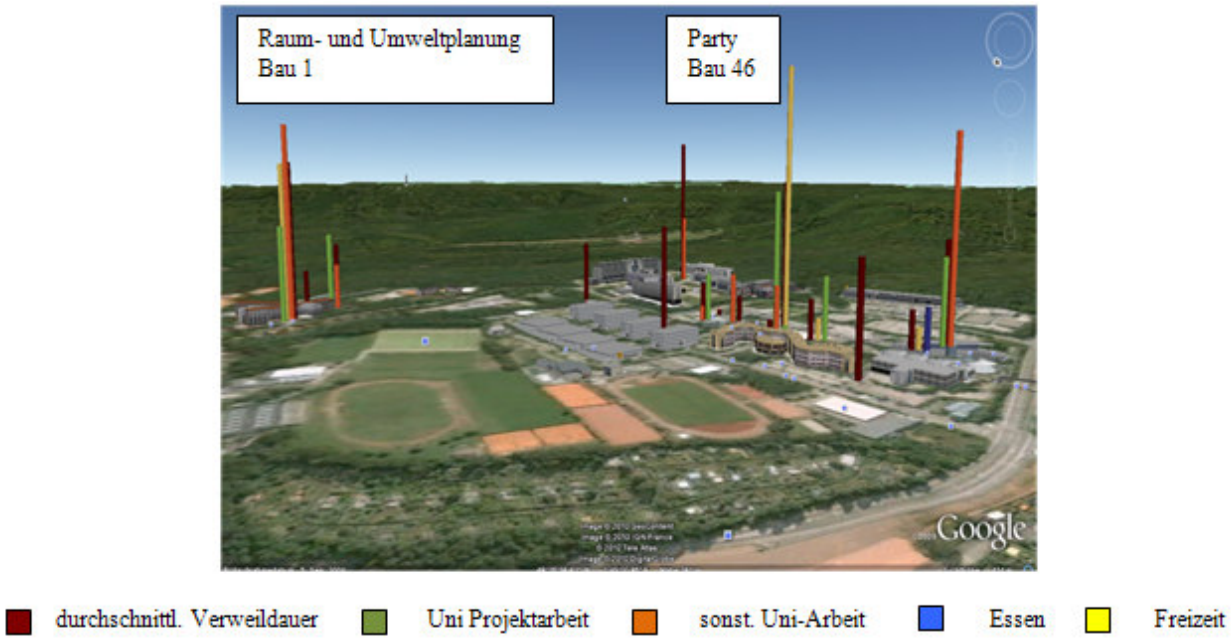

Fig. 2: Durchschnittliche Aufenthaltsdauer nach Zweck an der Universität, Analyse Probanden Moser & Sailer[CPE 2010]

3.2.3 ÖPNV-Analyse

Die konkrete planerische Anwendbarkeit kann anhand des folgenden Analysebeispiels aufgezeigt werden. Die linke Grafik zeigt die zurückgelegten Wege mit Hilfe des Fahrrads, die mittlere diejenigen mit dem Auto und die rechte die Wege mit dem ÖPNV. Hierbei wie wird insbesondere im zentralen Bereich der Karte eine starke Diskrepanz beider Karten deutlich. Dies beruht auf dem Fakt, dass der Weg zu einem größeren Einzelhandelsgeschäft, hauptsächlich für den täglichen Bedarf, überwiegend mit dem Fahrrad zurückgelegt werden muss, weil eine ÖPNV-Anbindung nicht existent ist. Dadurch ließe sich die planerisch relevante Aussage treffen, dass eine angebotene Buslinie kontinuierlich von Studenten frequentiert werden würde.

4 REFLEXION METHODISCHER SCHWIERIGKEITEN

Ein der größten methodischen Schwierigkeiten besteht darin, dass fehlerhafte kausale Zusammenhänge bezüglich der gesammelten Daten gezogen werden und dabei zu falschen Schlussfolgerungen gezogen werden. Damit verbunden ist auch die Tatsache, dass z.B. in dieser Übungsreihe kein repräsentativer Datensatz der Bevölkerung dargestellt wird und deshalb keine Schlussfolgerungen für die Planungen abgeleitet werden können. Davon abgesehen stellt der Transfer von nicht quantifizierbaren in quantifizierbare Daten schon eine grundsätzliche potenzielle Fehlerquelle dar. Neben dieser Problematik ist der private Datenschutz ein Thema, welches nicht außer Acht gelassen werden darf. Jedoch muss hierbei der Fakt herausgestellt werden, dass für den Planenden die Gesamtaggregation der Daten im Vordergrund steht, und somit die datenschutzrechtlich notwendige Anonymisierung der Daten problemlos erfolgen kann. Darüber hinaus lassen sich noch folgende Problematiken betrachten:

4.1 Erfassung & Bearbeitung

Eine überlegte Datenaufnahme mit möglichst wenigen Fehlerquellen sowie einer konsistenten Kausalkette sollte die Voraussetzung für eine solche Betrachtung sein. Bei dem vorliegenden Fallbeispiel bestand die Problematik darin, dass die manuelle Erfassung der Daten, welche nicht in Echtzeit und sekundengenau erfolgte, durch den Faktor Mensch als Fehlerquelle beeinflusst wurden. So wurden die Wegstrecken und Zeiten nur durch die nachträgliche Reflexion am Ende des Tages erfasst, was natürliche Verzerrungen und eine reduzierte Detailliertheit der Datensätze zur Folge hat. Auch die manuelle Integration in Google Earth führt zu Ungenauigkeiten und teilweise fehlerhaften Eingaben. Die individuelle Erfassung der jeweils eigenen Tätigkeit und deren Zuordnung zu den genutzten Status (Schlafen, Freizeit, Privat, etc.) ist zwischen den Probanden nicht immer konsistent, so dass teilweise ähnliche Tätigkeiten unterschiedlichen Kategorien zugewiesen wurden. Daraus resultiert eine Reduktion der Vergleichbarkeit. Alleine die unterschiedlichen Schreibweisen von Straßennamen, Stati und Orten haben zur Folge, dass die Auswertung verfälscht wurde. Des Weiteren wurden von einigen Gruppen Begriffe – wie etwa Pendler – doppelt und missverständlich vergeben. Dies hatte zur Folge, dass die Datensätze anderen Gruppen zugeordnet worden sind (an Stelle von Wochenendpendler, z.B. den Tagespendlern) und damit die Ergebnisse der einzelnen Gruppen teilweise andere Ergebnisse hervorbringen. Da zusätzlich keine standardisierte Auswertungsmethodik vorgegeben wurde, kamen daher unterschiedliche methodische Vorgehensweisen bei der Bearbeitung der Daten in die Betrachtung, was natürlich auch zu anderen Ergebnissen führt.

4.2 Interpretation

Der zweite wichtige Punkt ist die Interpretation der Daten. Hierbei muss entschieden werden, ob die ermittelten Daten belastbar sind und ob die ursprüngliche Intention anhand der Daten auch belegt werden kann. Insbesondere der Faktor der Scheinkorrelation ist hier als potenzielle Fehlerquelle anzuführen. Für die betrachteten Fallbeispiele bedeutet dies, dass klare Aussagen für die erhobene Probandengruppe getätigt

werden. Diese Daten sind jedoch nicht repräsentativ und damit nur im Falle für die beteiligten Studierenden gültig. Im Rahmen des Projektes zeigte sich, wie sich bei der Analyse der Datensätze weitere, noch nicht angedachte, Interpretationsmöglichkeiten durch die Kombination der Datensätze ergeben. So wurden z.B. aufgrund der Daten Schlafrhythmen und Aktivitätsprofile ausgewertet.

4.3 Visualisierung

Bei der Visualisierung der aufgenommenen oder analysierten Daten muss darauf geachtet werden, dass diese exakten Zahlwerte die Realität nicht so genau abbilden können, wie dies nach der Bearbeitung durch ein GIS-Programm o.ä. suggeriert wird. Deshalb eignen sich genau quantifizierbare Klassifizierung mit Hilfe von Kardinalskalen nicht so gut wie etwa Ordinalskalen mit Rangfolgen, welche etwa durch weiche Farbverläufe dargestellt werden können. Zusätzlich kann eine unterschiedliche Akzentuierung und Farbgebung beim Betrachter unterschiedliche Assoziationen hervorrufen. Da es keine standardisierte Methode der Visualisierung gibt und geben kann, wird diese immer durch persönliche Präferenzen und technische Fähigkeiten beeinflusst. Dies zeigt sich beispielhaft bei der folgenden Abbildung, welche auf dem exakt gleichen Datensatz beruhen. Hierbei war die Zielstellung für die Bearbeitergruppen, alle Wege aller Probanden im betrachteten Zeitfenster in einer für sie schlüssigen Darstellung zu veranschaulichen. Dabei zeigt sich, wie unterschiedlich diese Umsetzung wirken kann und wie lediglich durch die Modifikation der Darstellungsparameter, nicht aber der Ausgangsdaten, ein teilweise völlig unterschiedliches Erscheinungsbild hervorgerufen werden kann.

5 AUSBLICK

Neben diesen Wegemustern gibt es auch weitere zukünftige Forschungsfelder, in die der „Mensch als Sensor“ mit einbezogen werden kann. Ziel ist immer, ein umfassendes planerisches Bild einer Stadt zu gewinnen. So wie es erste Projekte zur Visualisierung von Kriminalitätsdelikten auf städtischer Ebene – das sog. Crime Mapping gibt [vgl. Wolf et. al. 2009], so könnten potentiell Wohlfühlräume charakterisiert und kartografiert werden. Des Weiteren wäre es möglich, über Verortungen von Nachrichten aus Web 2.0 Communities wie etwa Twitter – durch thematische Analyse und Verortung der jeweiligen Textbausteine – Gruppen wie z.B. kreative Milieus zu identifizieren. Auch wenn aktuell noch keine Aussage über die „Lebensqualitätswert“ oder das Image einer Stadt aufgrund dieser Daten getroffen werden kann, so können zumindest sektoral in der Stadtentwicklung Probleme und Potentiale aufgezeigt werden. Lokalisierte Datensätze und technische Analysemöglichkeiten entwickeln sich rasant und deren Verfügbarkeit nimmt zu. Es wäre wünschenswert, wenn diese Daten den planerischen Diskurs erweitern und neue Erkenntnisse für eine auf den Menschen und Bürger zentrierte Planung liefern könnten.

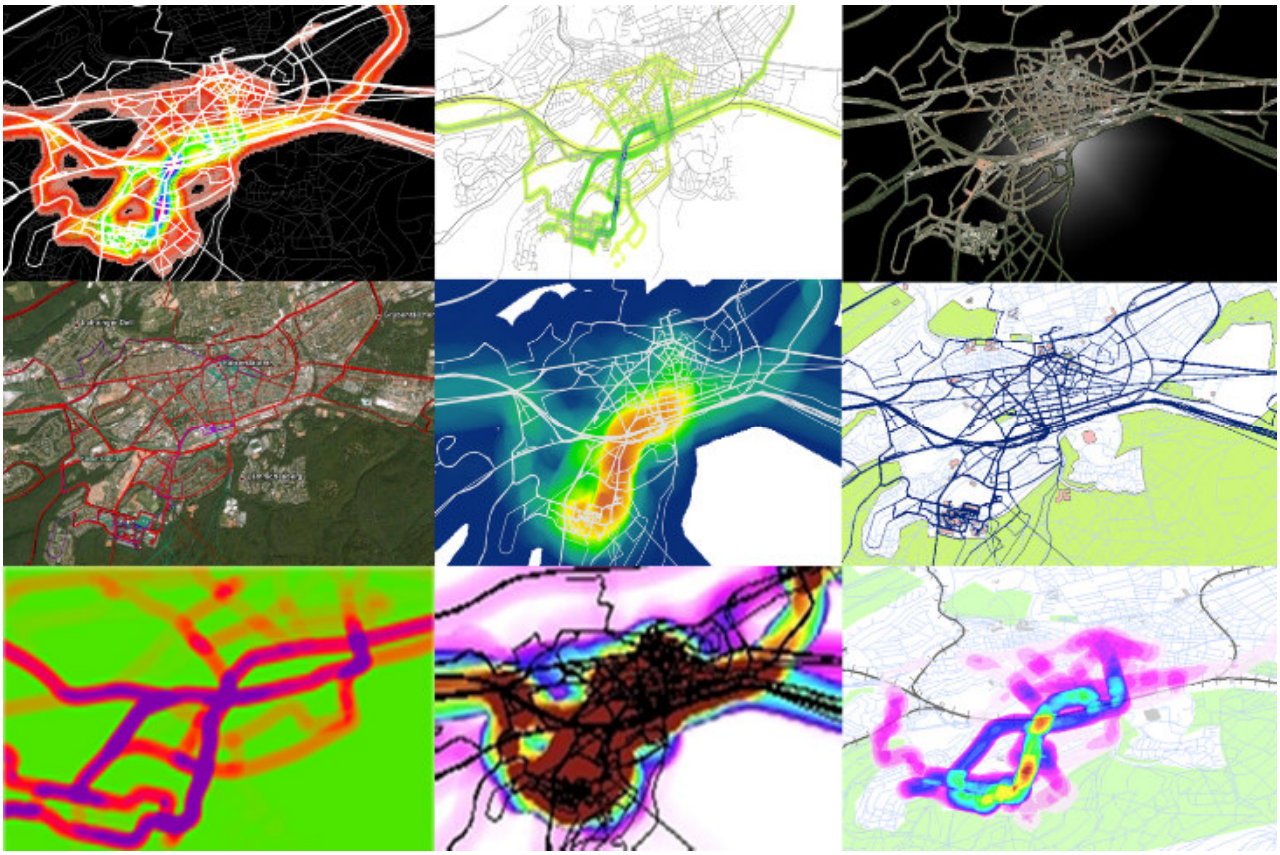

Fig. 5: Vergleich Visualisierungsmöglichkeiten aller getätigten Wege aller Probanden in Kaiserslautern während des Beobachtungszeitraums, Gesamtanalyse Probandengruppen [CPE 2010]

6 FAZIT

Den Menschen in den Fokus der planerischen Betrachtung zu stellen ist seit jeher oberste Planungsmaxime, ihn aber konkret als Messfühler für planerische Betrachtungen heranzuziehen, ist ein relativ neuer methodischer Ansatz, welcher jedoch enorme Potenziale für die Planung bietet. Einen Schritt zur Erforschung dieser Möglichkeiten stellen die beiden Projekte dar, die zeigen, dass sich trotz einiger Unzulänglichkeiten (Erfassungsprobleme, keine breite Datenbasis etc.) zumindest sektoral belastbare Daten extrahieren ließen, welche den planerischen Diskurs um neue Erkenntnisse bereichern können. In diesem Kontext sind die Ergebnisse deshalb beachtenswert, da die studentische Versuchsgruppe mit nur den ihnen zur Verfügung stehenden Daten sowie dem vorhandenen Basiswissen in GIS-Software eine Vielzahl an planerisch relevanten Ergebnissen und Aussagen (Taktung, Auslastung und Linienführung ÖPNV-Systeme, Frequentierung der Mensa- und Kioskstandorte, unterschiedliches Einkaufsverhalten der weiblichen und männlichen Probanden) ableiten und visualisieren konnten. Dabei zeigt sich an den erzielten Ergebnissen deutlich die hohe Relevanz, die dem Datenschutz in zukünftiger Entwicklung generell zukommen muss. Denn in Zeiten eines zunehmendes Data Minings und der damit verbundenen Verschneidung unterschiedlichster Daten (ökonomischer, sozialer Art) bestehen weitreichende Eingriffe in den Persönlichkeitsrechte von Kunden und Bürgern. So wichtig die Erhebung und Analyse von geocodierten und personenbezogenen Daten für die Stadtforschung auch ist, so wichtig ist hierbei eine Anonymisierung und Aggregation der Daten, um individuelle Auswertungen und Datenmissbrauch zu vermeiden.

In technisch-methodischer Hinsicht zeigte sich, dass die Erhebung mittels manueller Eingabe im Vergleich zur automatisierten Erfassung über GPS Vor- und Nachteile hat. Bei manueller Erfassung reduziert sich die Genauigkeit der erfassten Ortsdaten, da eine metergenaue Eintragung (z.B. der Straßenseite) für die Probanden zu aufwändig ist, während eine Erfassung via GPS dies grundsätzlich ohne Mehraufwand ermöglicht. Allerdings sind GPS-Empfänger anfällig bezüglich Bebauung und Wetter (Wolkendecke), wodurch die Genauigkeit der GPS-Signale stark beeinträchtigt werden kann und damit eine Datenbereinigung erfordert. In Kombination mit den Diaries erfolgt bei der manuellen Erfassung zudem gleichzeitig eine Aufzeichnung der Statuswechsel. Insgesamt erfordert die automatisierte Erfassung im Vergleich beim jetzigen Stand der Technik einen höheren technischen und finanziellen Aufwand.

Dementsprechend wird sich eine automatische Erfassung – trotz höherer Genauigkeit und geringerem Aufwand für den Probanden – erst langfristig durchsetzen. Zum aktuellen Zeitpunkt hängt der Einsatz von der jeweiligen Untersuchungsfrage und dem Umfang des Projektes ab. Für die Analyse von Verkehrswegen und der Nutzung des ÖPNV bietet die genutzte Methode somit einen vielsprechenden Ansatz. Gerade eine längerfristige Erfassung und Auswertung von Fahrradrouten könnte auf diesem Wege erfolgen.

Das Forschungsprojekt „Tracking People“ stellt hierbei eine Momentaufnahme dar, die zeigt, was alleine nur durch Verortung von Wegbeziehungen und Tätigkeiten schon auf einer einfachen Stufe möglich ist. Zudem gibt es – im Kontext mit den anderen vorgestellten Projekten – einen Ausblick darauf, welche planerischen Erkenntnisgewinne möglich wären. Anknüpfungspunkte für zukünftige Projekte wären z.B. die Kombination mit Biodaten oder anderen ortsbezogenen Daten. Sehr wahrscheinlich werden in diesem Forschungsfeld neue Methoden der Stadtanalyse entstehen, die Planern neue Wege in der Entscheidungsfindung eröffnen. Zusätzlich könnten durch Phänomene wie etwa Crowdsourcing die Aspekte des Web 2.0, durch ihre Lokalisierungen räumlicher Daten, auf einer neuen Ebene nutzbar gemacht werden.

7 DANKSAGUNG

Die Autoren möchten sich bei allen teilnehmenden Studierenden bedanken, die mit Engagement und Ausdauer zum Gelingen der Projekte beigetragen und durch ihre kritische Reflexion wichtige Hinweise für die Methodenentwicklung gegeben haben. Dank geht auch an die hilfswissenschaftlichen Mitarbeiter Willi Wendt und Timo Wundsam, die maßgeblich an der technischen-methodischen Verbesserung im Rahmen von Tracking People 2.0 beteiligt waren.

1 ABSTRACT

Internetfähige Mobiltelefone sind in den letzten Jahren zum Standard geworden. Die mobile Verfügbarkeit des Internets bietet Städten und Regionen vielfältige Möglichkeiten, Informationen direkt vor Ort bereit zu stellen. Bisher waren städtische Informationssysteme nur „statisch“ im Netz vorhanden und wurden in der Regel am heimischen PC abgerufen. Das mobile Internet ermöglicht es Städten und Regionen, die bestehenden Informationssysteme nun auch mobil zur Verfügung zu stellen. Die Projektgruppe „Mar.Vis – Marketing.Visualisierung“ des Lehrgebietes cpe | Computergestützte Planungs- und Entwurfsmethoden in Raumplanung und Architektur an der TU Kaiserslautern entwickelte basierend auf der QR-Code-Technologie das mobile Informationssystem „Urban-Code“: Webinhalte lassen sich einfach und effektiv direkt vor Ort mobil verfügbar machen – jeder Besitzer eines internetfähigen Kamerahandys kann darauf zugreifen. Mit dem „Urban-Code“ können neben klassischen Webseiten auch multimediale Inhalte wie Filme und Audiospots mit realen Objekten verknüpft werden. Das folgende Paper gibt eine Übersicht der verschiedenen Anwendungsmöglichkeiten und einen Ausblick auf die Entwicklungstrends der Mobilfunktechnologie und Location Based Services.

2 MOBILE INFORMATIONSSYSTEME

2.1 Trends und Probleme bei der mobilen Informationsbeschaffung

„Das ganze Internet auf dem Handy ist die pure Propaganda!“, schrieb die Süddeutsche Zeitung noch 1999, das seien „unerfüllbare Erwartungen“ [Kurbjuweit et al., in: Der Spiegel vom 07.12.2009, S.71]. Heute boomt der Verkauf internetfähiger Mobiltelefone. Die Verwendung von Handys eben nicht nur zum Telefonieren sondern zur Nutzung einer Vielzahl zusätzlicher multimedialer Funktionen ist alltäglich geworden. Noch vor wenigen Jahren ließ die viel zitierte „Usability“ auf Mobiltelefonen zu Wünschen übrig: Umständliche Bedienung, instabile Software sowie Displaytechniken, die höchstens zum Schreiben von SMS geeignet waren. Heute verbreiten sich Smartphones mit intuitiven Touchscreens zunehmend schneller: Audio und Videodateien abzuspielen gehört ebenso zum Standard wie der Zugriff auf mobile Inhalte im Internet. Einhergehend mit den immer günstiger werdenden Internet-Flatrates wandelt sich der Umgang mit Mobiltelefonen dahingehend, dass fast jeder sein Mobiltelefon als „kleinen digitalen Begleiter“ dabei hat. Die Vision des „Ubiquitous Computing“ [Weiser 1993] – der Allgegenwart rechnergestützter Informationsverarbeitung – lässt sich an diesem Trend ablesen. Mit dem Smartphone kann der User fast alle erdenklichen Dinge anstellen, seien es auch oft nur Spielereien [vgl. Streich 2005, S.190: Der homo ludens als Quelle der Erkenntnis und des wissenschaftlichen Arbeitens]. Erweitert wurde die mobile Internetnutzung in den letzten Jahren durch die Netbooks und jüngst durch das iPad von Apple. Die „Multimediaassistenten“ der Zukunft ermöglichen also den uneingeschränkten Zugriff auf alle Informationen – jederzeit und allerorts.

Laut dem Spiegel vom 07.12.2009 ist eines der größten Probleme bei der Informationsbeschaffung im Internet das dort herrschende Überangebot. Wissen ist überall und ständig verfügbar und der Nutzer will es überall und ständig haben! Das hat zur Folge, dass jede Neuigkeit die volle Aufmerksamkeit verlangt [Kurbjuweit et al., in: Der Spiegel vom 07.12.2009, S.72]. Das Internet ist zwar im Alltag angekommen, aber der Nutzer weiß in vielen Fällen nicht, wie er der Informationsflut Herr werden soll. Es stellt sich oftmals eine Überforderung ein [zur aktuellen Diskussion über den Umgang mit allseits digital einfallender Information vgl. Schirrmacher 2009].

Hier stellt sich die Frage: Wie kann dem Nutzer die richtige Information zur richtigen Zeit und am richtigen Ort vermittelt werden? Gerade im mobilen Bereich will nicht jeder Nutzer eines Mobiltelefons mit mobilem Internet immer und überall erfahren, welche interaktiven, sehenswerten, „wichtigen“ oder eben „unwichtigen“ Dinge gerade um ihn herum oder sogar weltweit geschehen.

Das Medium Internet sollte zurücktreten und im übertragenen Sinne nicht mehr als solches erkennbar sein. Es soll nur „Mittel zum Zweck“ sein und somit quasi unsichtbar. Ziel ist es, dass der Nutzer nur noch das erfährt und sieht, was er selbst gerade will. Es bedarf einer Filterung, und zwar einer Filterung, die nicht der Nutzer gegenüber einem Informationsberg unternimmt, der mitunter auch viele Falschinformationen enthalten kann. Es ist daher sinnvoll, Objekte, die Interesse wecken können oder sollen, zum Input einladen zu lassen. Die Nutzung des Internets findet also erst nach geweckтem Interesse direkt vor Ort statt, und zwar gezielt – nicht in Form einer aktiven Suche des Nutzers im Internet, sondern indem das Objekt des Interesses selbst dem Mobiltelefon den entsprechenden Input gibt.

2.2 Verfügbare Technologien für mobile Informationssysteme

Wenn nun also nicht der Nutzer selbst mit seinem Mobiltelefon im Internet nach Informationen suchen soll, wie gelangen die Informationen dann zum Interessenten? Im Folgenden wird ein Überblick über die aktuellen Systeme QR-Code, Bluetooth, RFID/ NFC, Google Goggles und Location Based Services sowie deren Anwendungsmöglichkeiten im Bereich der mobilen Informationssysteme gegeben.

2.2.1 QR-Code

Seit einigen Jahren hat sich vor allem in Japan ein System durchgesetzt: Der so genannte QR-Code, der „Quick-Response-Code“. Es handelt sich dabei um einen schwarzweißen Code ähnlich dem Strichcode, der zur Preisabfrage in Supermärkten dient. Anhand des QR-Codes lassen sich Texte, Internetadressen, digitale Visitenkarten oder Telefonnummern mit bis zu 250 Zeichen verschlüsseln. Wird dieser Code mit dem Kamerahandy fotografiert, so wird über eine Dechiffrier-Software der Text entschlüsselt, der sich hinter dem QR-Code verbirgt. Die Dechiffrier-Software ist auf neueren Mobiltelefonmodellen bereits vorinstalliert oder kann im Internet kostenfrei bezogen werden . Idealerweise stellt der Text eine Internetadresse dar, auf die das Handy direkt zugreifen kann. Somit lässt sich über den Code gezielt vor Ort eine bestimmte Internetseite abrufen. Aber auch auf Dateien, die online verfügbar sind, lässt sich so mit dem Handy zugreifen. Ohne dass der Nutzer auf Internetseiten suchen muss, wird direkt ein Film oder eine Tondatei auf dem Handy abgespielt. Der QR-Code ist eine einfache zweidimensionale Grafik und hat daher den Vorteil, dass er sich problemlos auf Plakaten, Schildern oder per Aufkleber am Objekt des Interesses platzieren lässt.

Fig. 1: Anwendungsbeispiel QR-Code

2.2.2 Bluetooth

Ohne mobile Internetverbindung kommt das Bluetooth-System aus. Hierbei werden dem Handy über Funk Daten übermittelt. Verwendung findet das System vor allem im privaten Datenaustausch, doch lassen sich über Bluetooth-Sendegeräte auch Informationen über ein bestimmtes Objekt vor Ort vermitteln. Bedingung ist, dass der Mobilfunknutzer den Bluetooth-Empfang auf seinem Handy oder Netbook/ iPad aktiviert hat. Das Bluetooth-System sendet die Informationen permanent an alle empfangsbereiten Geräte in Reichweite, der Nutzer kann die Annahme der Information jedoch auch ablehnen. Ist sie erwünscht, können Filme, Bilder, Tondateien und Texte objekt- oder standortbezogen abgerufen werden, ohne dass der Nutzer mobil online gehen muss. Von Nachteil beim Bluetooth-System ist die geringere Geschwindigkeit bei der Datenübertragung. Das Versenden größerer Dateien dauert also wesentlich länger als über das Hochgeschwindigkeitsinternet HSDPA.

Die Bluetooth-Technologie wird bereits seit einigen Jahren von Unternehmen als Instrument des mobilen Marketings genutzt. Der 2008 von der Zeitschrift Absatzwirtschaft herausgegebene „Praxisleitfaden MOBILE MARKETING“ [Steimel et al. 2008] enthält hierzu diverse Beispiele. Abgesehen von interaktiven Werbeflächen der Firma Wall und Sendeterminals der Telekom gab es allerdings bisher kaum Anwendungen der Bluetooth-Techologie als Informationsträger im städtischen Raum. Bluetooth-Information oder Bluetooth-Marketing beschränkte sich auf geschlossene Veranstaltungen wie Fachmessen, Festivals oder Sportevents. Neue Wege geht hier die Stadt Koblenz, deren städtisches Bluetooth-Informationssystem in Kapitel 3.3 näher beschrieben wird.

2.2.3 RFID/ NFC

Ein System, das für Handys noch nicht zur Standardausstattung gehört ist das sogenannte RFID-System. RFID steht für „Radio Frequency Identification“ und bedeutet „Funkerkennung“. Das System funktioniert, indem ein Gegenstand mit einem Transponder ausgestattet wird, der auf die Anfrage eines Lesegerätes reagiert und diesem Informationen überträgt. Für die Datenübertragung ist kein direkter Kontakt zwischen Lesegerät und Transponder erforderlich. Das System findet derzeit bereits in vielen Bereichen Anwendung, zum Beispiel in der Logistik und in Kaufhäusern. Seit einigen Jahren werden auch Haus- und Zootiere mit einem RFID-Transponder unter der Haut gekennzeichnet, somit lassen sich die Tiere einwandfrei identifizieren und dem Besitzer zuordnen. Dabei handelt es sich jedoch nur um einen kleinen Teil des

möglichen Einsatzspektrums der RFID-Technologie. Im Bereich der mobilen Anwendung wird die RFID-Technologie als „Near Field Communication“, kurz NFC, bezeichnet. Ab Ende 2010 sollen Mobiltelefone zunehmend mit einem NFC-Lesegerät ausgestattet werden. Das System wird sich möglicherweise zu einer Standardanwendung von Mobiltelefonen entwickeln. Bei mobilen Informationssystemen könnte die Technologie wie folgt Verwendung finden: An Orten von Interesse ist ein Hinweis auf den vorhandenen NFC-Transponder angebracht. Der Nutzer hält das Lesegerät – in diesem Fall das Mobiltelefon – in die Nähe des Transponders und empfängt einen weltweit einzigartigen „Festcode“ auf sein Telefon. Diesem Code ist eine Internetadresse zugeordnet, über die sich nun wie beim QR-Code die vielfältigsten Informationen übermitteln lassen. Der Vorteil gegenüber den QR-Codes besteht darin, dass der Nutzer keinen Code abfotografieren muss, sondern lediglich das Gerät in die Nähe des Transponders halten muss. Bereits 2006 wurde auf der Nordseeinsel Sylt ein solches mobiles Informationssystem mittels NFC-Technologie aufgebaut. An bestimmten Punkten wie Restaurants oder Bushaltestellen wurde ein Transponder angebracht und der Nutzer konnte sich vor Ort informieren. Das System konnte sich allerdings nicht richtig durchsetzen, da es lediglich mit einem Handymodell funktionierte, das auf der Insel ausgeliehen werden musste. Außerdem konnte das Telefon die Inhalte nicht ansprechend auf dem kleinen und niedrig auflösenden Display vermitteln.

2.2.4 Location Based Service

Eine ähnliche Technik, die es dem Nutzer ermöglicht selektive Informationen vor Ort zu erhalten ist der Location Based Service. Mittels GPS (Global Positioning System) kann der Standort von Mobiltelefonen mit GPS-Empfänger ermittelt werden. Auch über die Sendemasten des Mobilfunknetzes kann eine Ortung erfolgen: Eine Software ermittelt den Standort des Mobiltelefons über die „Cell-ID“ der jeweiligen „GSM-Zelle“ (Global System for Mobile Communications), die durch die Verteilung der Sendemasten entsteht. Zusätzlich kann über einen im Mobiltelefon eingebauten digitalen Kompass neben der genauen Position des Nutzers die Blickrichtung festgestellt werden. Mit diesen Bezugspunkten ist es möglich, Informationen zum gerade anvisierten Objekt in Echtzeit im Handydisplay darzustellen.

Die Positionsermittlung über die Cell-ID findet zum Beispiel bei der Firma Google Anwendung: Bei der Positionsermittlung des Google-Dienstes „GoogleMaps“ wird auf diese Methode zurückgegriffen. Fraglich ist allerdings die Vorgehensweise der Firma Google: Die Cell-IDs wurden nicht direkt von den Mobilfunknetzbetreibern bezogen sondern indirekt ermittelt: Google sammelte die Cell-IDs mit Hilfe von Handynutzern, die diese über ein Mobiltelefon mit GPS-Empfänger preisgaben. Seitdem kann Google auch den Standort von Nutzern ermitteln, deren Telefon über keine GPS-Funktion verfügt.

2.2.5 Google Goggles

Eine weitere Entwicklung, die es ermöglicht Informationen zu diversen Objekten, Gegenständen oder Gebäuden zur Verfügung zu stellen, ist Google Goggles. Der Ort oder Gegenstand von Interesse wird abfotografiert und das Mobiltelefon stellt im Browser die objektspezifischen Informationen zur Verfügung. Das System funktioniert über eine Bilderkennungssoftware, die den abgebildeten Gegenstand erkennt und dann gezielt im Internet nach diesem sucht. Allerdings funktioniert das System noch längst nicht bei allen Gegenständen sondern nur bei bekannten Sehenswürdigkeiten, Büchern, berühmten Kunstwerken und Logos. Google Goggles ist bisher auch nur für das Handybetriebssystem Android verfügbar. Die Software befindet sich noch im Beta-Status und ist dementsprechend noch nicht ausgereift.

2.3 Anforderungen an mobile (städtische) Informationssysteme

Drei technische Grundvoraussetzungen muss das Mobiltelefon erfüllen, um die mobilen Informationssysteme im vollen Umfang nutzen zu können:

- Das Handy muss über einen Internetzugang verfügen, idealerweise über eine Internet-Flatrate, um zusätzlich anfallende Verbindungskosten zu vermeiden. In Zukunft ist davon auszugehen, dass neu abgeschlossene Mobiltelefonverträge bereits eine Internet-Flatrate beinhalten.
- Das Handy benötigt eine gut auflösende Kamera – mittlerweile gehört auch dieses Ausstattungsmerkmal zum Standard.
- Für die genaue Positionsbestimmung des Mobiltelefons ist ein GPS-Empfänger nötig und um die Blickrichtung zu ermitteln ein integrierter digitaler Kompass.

Angesichts aktueller Verkaufszahlen von Smartphones, die als Motor des mobilen Internets angesehen werden, kann die These aufgestellt werden, dass spätestens in fünf Jahren fast jeder zweite Bürger mobile Informationsdienste nutzen wird und ein Gerät mit den oben genannten Spezifikationen besitzt.

In der Praxis bieten die unterschiedlichen Lösungen der mobilen Informationssysteme sowohl Vor- als auch Nachteile. Der Vorteil der QR-Code-, Bluetooth- und NFC-basierten Systeme besteht darin, dass die objektspezifischen Informationen direkt und ohne Umwege auf dem Mobiltelefon dargestellt werden. Bei den Informationen handelt es sich um solche, die nicht auf den ersten Seiten einer Suchmaschine erscheinen, insbesondere bei allgemeinen Suchbegriffen. Davon abgesehen muss bei Suchmaschinen zusätzlich der Name des gesuchten Objektes per Hand eingeben werden. Sucht der Nutzer beispielsweise nach einer Kurzdokumentation über den Baustellenverlauf einer Stadt, so wird er diesen Film nicht auf den ersten zehn Seiten der Suchmaschine finden, wenn er nur den Stadtnamen als Suchbegriff eingibt. Alles was über das Eingeben des Stadtnamens per Mobiltelefontastatur hinausgeht, ist dem Nutzer nicht mehr zuzumuten und nicht praxisgerecht. Beim System Google Goggles bleibt dem Nutzer das Eingeben des Suchbegriffs zwar erspart, die Suchergebnisse sind allerdings nach wie vor allgemeine Informationen, in aller Regel ist der erste Treffer das Objekt betreffend ein Wikipedia-Eintrag. Exakte und deutlich umfangreichere oder speziellere wie ortsspezifische Informationen lassen sich mit dem System hingegen nicht vermitteln.

Hinsichtlich der Aktualität existieren zwischen der QR-Code- und NFC-Technologie auf der einen Seite und Google Goggles auf der anderen Seite zwei grundlegende Unterschiede: Während sich die Inhalte, die sich hinter den QR-Codes und den NFC-Transpondern verbergen, problemlos aktualisieren lassen, indem die verlinkte Internetseite mit neuen und aktuellen Inhalten versehen wird, können bei Google Goggles hingegen auch ältere und nicht mehr aktuelle Information weiterhin als erster oder zweiter Treffer der Suche erscheinen. In einigen Bereichen spielt die Aktualität der Information nicht die entscheidende Rolle – soll aber vor Ort eine wichtige und hochaktuelle Information vermittelt werden, ist dies ein entscheidender einschränkender Faktor für das System Google Goggles.

3 MOBILE INFORMATIONSSYSTEME IN STADT UND REGION IN DER PRAXIS

Die Diskussion über mobile Informationssysteme, der Bereitstellung von mobilem Content, erinnert zum heutigen Zeitpunkt sehr stark an die Diskussion der Frage „Brauchen wir überhaupt eine Homepage?“ mit Vertretern von Städten und vor allem kleineren Gemeinden um das Jahr 2000. Die Rahmenbedingungen waren seinerzeit auch bei der Diskussion über Endgeräte und Infrastruktur sehr ähnlich: Es fehlten Internetanschlüsse allgemein, High-Speed-Internet war nur an Forschungseinrichtungen verfügbar und vor allem gab es auch nur einen Bruchteil an „richtigen“ Internetnutzern. Heute ist das „bottleneck“ der Übertragungskapazität überwunden, fast jeder benutzt das Internet und es gibt auch fast keine Gemeinde mehr, die sich nicht „im Netz“ präsentiert. Einzig die stationäre Bindung an die Informationsbeschaffung ist derzeit noch zu überwinden.

Die mobilen Informationssysteme bieten ein großes Potenzial für die Vermittlung von objektbezogenen Inhalten im touristischen Bereich. Zudem lassen sich auch Inhalte aus dem stadtplanerischen Bereich darstellen – der Bürger besitzt über einen neuen Kanal weitere Möglichkeiten der Partizipation. Zum Beispiel könnte der Interessierte noch auf der „grünen Wiese“ den Bebauungsplan für das Gelände oder verschiedene Varianten für die Baumaßnahme betrachten. In einem weiteren Schritt wäre es denkbar, direkt über eine der Varianten abzustimmen oder ein Feedback zu senden. Für diese Anwendungen bietet sich der QR-Code im Sinne des „Urban-Codes “[1] an. Sowohl touristische, als auch planungsrelevante Inhalte können über den „Urban-Code“ vor Ort und je nach Einsatzgebiet über Sehenswürdigkeiten, Baumaßnahmen, Stadtführungen und vieles mehr informieren.

[1] Siehe www.urban-code.de

Fig. 2: QR-Code zum Film: “Urban-Code” – www.mar-vis.de/uc/uc.3gp

3.1 Beispiel: Urban-Code Aalen

Am Beispiel des Urban-Code-Systems der Stadt Aalen lässt sich gut erläutern, welche Information zur Verwendung im mobilen Informationssystem sinnvoll ist und welche nicht. Gegenüber einem klassischen Hinweisschild muss die mobile Information einen erkennbaren Mehrwert haben. Die simple Wiederholung dessen, was auf dem Schild steht, ist nicht von Interesse. Auch wenn zusätzliche Informationen mobil zur Verfügung gestellt werden – niemand will sich längere Texte auf seinem Mobiltelefon durchlesen. Die multimedialen Potentiale des Gerätes sollten ausgeschöpft werden, damit die Aufmerksamkeit erhöht und durchaus auch ein Spieltrieb geweckt wird. Die Informationen sollten außerdem kompakt vermittelt werden, da sich die wenigsten Nutzer im Rahmen einer touristischen oder ähnlichen Tätigkeit unzumutbar lange mit ihrem Mobiltelefon beschäftigen wollen. Am besten geeignet zur kompakten und eingängigen Information sind somit Filme, die auf aktuellen Mobiltelefonen in ausreichend hoher Qualität wiedergegeben werden können.

Von der Dokumentation bis zur Animation lässt sich in ein bis zwei Minuten eine ausreichende und einprägende Information gestalten. Auch Audioinhalte können interessanter gestaltet werden, indem sie zum Beispiel durch einen virtuellen „Avatar“, der im Idealfall einen Bezug zur Information hat, vorgetragen werden. Beispielhaft sei hier der „Spion von Aalen“ genannt – ein heldenhafter Charakter aus dem Mittelalter, dem in Aalen ein Denkmal gesetzt wurde. Mithilfe von 3D-Software kann die Statue des Spions zum „Leben“ erweckt werden und dem Nutzer Anekdoten aus der Aalener Stadtgeschichte erzählen.

Insbesondere Informationen, die über „analoge” Wege schlecht vermittelbar sind, lassen sich über Filme hervorragend mit dem Handy verknüpfen: Lokale Besonderheiten wie Geschichten, die beispielsweise von einem „Einheimischen” erzählt werden, vielleicht seine eigenen Erlebnisse, können kulturelle Eigenarten und Erinnerungen wach halten. Temporäre Ereignisse, wie zum Beispiel Volksfeste können während des restlichen Jahres per mobil abrufbaren Film eindrucksvoll wiedergegeben werden. Informationen, die an einer bestimmten Stelle abgerufen werden (zum Beispiel über QR-Code oder NSC), können den aktuellen Blickbezug des Nutzers aufnehmen und beispielsweise die selbe Stelle in historischen Ansichten wieder aufleben lassen oder einen zukünftigen Zustand vermitteln. Bei städtebaulichen oder architektonischen (Groß-) Projekten kann so ein Eindruck dessen, was geplant ist, schon während der Bauarbeiten nahe gebracht werden. Vor allem 3D-Stadtmodelle lassen sich hierfür mit den mobilen Informationssystemen verbinden. Dies beinhaltet einen weitaus größeren inhaltlichen Wert, als wenn das Modell weit entfernt vom Ort des Geschehens vor dem heimischen PC betrachtet wird.

Fig. 3: Der „Spion von Aalen“ – zum Leben erweckt mittels 3D-Software

3.2 Beispiel: Stadtwiki Koblenz

Enzyklopädien im Internet haben Hochkonjunktur – das wohl populärste Nachschlagewerk ist die Plattform Wikipedia mit mehr als 650.000 Artikeln in der deutschen Version. Doch haben es im Wikipedia vor allem Themen schwer, die sich ausschließlich mit lokalem Sachbezug befassen.

Seit 2003 gibt es regionale Pendants zur großen Schwester: Die Stadtwikis. Das verbindende Ziel der offenen Stadtwiki-Gemeinschaft ist es, Informationen über die jeweilige Stadt zu sammeln und der Allgemeinheit frei zur Verfügung zu stellen. Mit dem Stadtwiki Karlsruhe ging 2004 die erste regionale Online-Enzyklopädie in Deutschland an den Start – und viele Städte zogen nach. Auch eine Gruppe engagierter Koblenzer begann Mitte letzten Jahres mit dem Aufbau einer Informationsplattform für die Stadt und die Region Koblenz. Neben klassischen Informationen über Sehenswürdigkeiten, Museen und Denkmäler sollen auch Koblenzer Vereine die Möglichkeit haben, sich und Ihre Aktivitäten auf dieser Plattform einer breiten Öffentlichkeit zu präsentieren.

Der Verein „Freies-Wissen-Online e.V.“, Betreiber des Stadtwiki Koblenz , legt hier die Verantwortung für den Aufbau eines mobilen Stadtinformationssystems in die Hände der Stadtwiki-Community, also der Koblenzer Bürger. Die Erfahrungen aus der großen Enzyklopädie Wikipedia und auch dem Stadtwiki Karlsruhe haben gezeigt, dass Sachlichkeit, Korrektheit und Aktualität der Informationen durch die Pflege der Autorengemeinschaft gewährleistet werden können. Dies bewies 2004 eine Studie der Firma IBM und dem Massachusetts Institute of Technology (MIT) [Viégas et al. 2004, S.575ff] mit dem so genannten Historyflow-Verfahren, mit dem die Evolution von Wiki-Artikeln untersucht wurde.

Im Vergleich zu anderen Stadtwikis gibt es beim Stadtwiki Koblenz jedoch einen wesentlich Unterschied: Die Informationen des Stadtwikis sollen nicht nur im Netz verfügbar, sondern per QR-Code auch am Objekt vor Ort per Mobiltelefon abrufbar sein. Hierzu sollen die Autoren der jeweiligen Artikel die Möglichkeit haben, sich automatisch einen QR-Code mit der entsprechenden Internetadresse ihres Artikels zu generieren. Außerdem sollen sie den QR-Code auch direkt als Schild im Stadtwiki-Design bestellen können.

3.3 Beispiel: Bluetooth-Marketing Koblenz

Die Stadt Koblenz nahm 2008 den Betrieb eines auf Bluetooth basierenden Informationssystems auf. Dreizehn über die Stadt verteilte Sendestationen versorgen Besucher und Bürger kostenlos mit Informationen: Sobald sich die Nutzer mit ihrem Mobiltelefon auf rund 30 Meter einer Sendestation nähern, erhalten sie Textnachrichten, kurze Videos oder Audiodateien mit Informationen zu dem Ort, an dem sie sich gerade befinden. Die Besonderheit des Koblenzer Systems ist die zentrale Steuerung: Jede Sendestation ist per UMTS oder Kabelzugang mit dem Internet verbunden – die zu sendenden Inhalte können von einem zentralen Rechner aus jederzeit modifiziert werden. So konnte zum Beispiel an der Sendestation am Deutschen Eck während der Veranstaltung „Rhein in Flammen“ das aktuelle Bühnenprogramm und kurz-

fristige Änderungen per Bluetooth an die Besucher verschickt werden. Diese Flexibilität ist der große Vorteil des von der Koblenzer Firma WizAi Solutions entwickelten Systems. Ein Nachteil besteht allerdings in den relativ hohen Kosten: Insgesamt investierte die Stadt rund 240.000 Euro in Aufbau und Betrieb.

4 FAZIT

Das mobile Internet ist für sich bereits als mobiles Informationssystem zu bezeichnen. Allerdings sollte das Ziel eines mobilen Informationssystems nicht darin bestehen, dem Nutzer eine unüberschaubare Menge an Objektinformation zur Verfügung zu stellen. Stattdessen müssen Informationen sinnvoll gefiltert werden und der Nutzer sollte nur genau die Informationen erhalten, die er vor Ort benötigt. Insbesondere bei mobilen Informationssystemen ist dies besonders wichtig, da auf Grund von Hardwarefaktoren wie Displaygröße des Endgerätes und Übertragungsgeschwindigkeit des verfügbaren Netzes ein Überangebot an Informationen kontraproduktiv wirkt.

Im Gegensatz zu vielen anderen Ländern hat Deutschland in der Entwicklung von Anwendungsbereichen mobiler Informationssysteme noch Nachholbedarf. Dies liegt zum Großteil nicht an der technischen Entwicklung oder den Kosten, sondern in der Akzeptanz der Anwender. Deshalb ist es besonders wichtig bei der Konzeption von mobilen Informationssystemen den Fokus auf einen sinnvollen Inhalt zu legen, denn ein Informationssystem ist eben nur so gut wie die angebotenen Inhalte. Erhält ein Nutzer vor Ort nicht die gewünschten Informationen, wird er das System nicht akzeptieren und keine weitere Nutzung vornehmen. Das Informationssystem verfehlt somit seinen Zweck.

Technologisch sind die Weichen für einen erfolgsversprechenden Ausbau von mobilen Informationssystemen mittlerweile gestellt: Die Preise für mobile Internetflatrates sinken stetig, fast alle neuen Mobiltelefone verfügen über die entsprechenden Schnittstellen und Techniken. Es ist sogar zu vermuten, dass es in absehbarer Zeit keine Mobilfunkverträge mehr ohne Internetoption geben wird, denn viele Funktionen der Mobiltelefone werden ausschließlich durch eine mobile Internetverbindung funktionieren. Schon heute können mit Hilfe der QR-Codes Informationen mit einem realen Objekt verknüpft und per Mobiltelefon abgerufen werden. Die RFID- beziehungsweise NFC-Technologie befindet sich gerade im Einzelhandelsbereich im Aufbruch und wird in absehbarer Zeit ihre Potenziale auf mobilen Endgeräten ausspielen. So entstehen neue Möglichkeiten das Abrufen von Informationen zu erleichtern.

Google Goggles sollte insbesondere unter Datenschutzgesichtspunkten als kritisch eingestuft werden, da Google über die Nutzung des Systems an zahlreiche Daten und Interessen des Nutzers gelangt. Insofern ist es durchaus möglich, dass die Bevölkerung dem System äußerst skeptisch gegenüber stehen kann und es ähnliche Abwehrreaktionen geben könnte wie gegenüber dem Google-Dienst „Street-View“. Auch die automatische Standorterkennung per GPS oder Verortung der Cell-ID werden von der Bevölkerung aus Datenschutzgründen mitunter kritisch betrachtet. Ohne das Wissen des Nutzers könnten Bewegungsprofile aufgezeichnet und zum Beispiel für individuell angepasste Werbung missbraucht werden.

Die vorgestellten Beispiele zeigen allerdings, dass Städte und Gemeinden sich mit diesem Thema auseinander setzen und zunehmend die Weichen für mobile Informationssysteme und zukünftige Kommunikationswege stellen: Interessierte Bürger und Touristen können Informationen rund um die jeweilige Stadt und Region unkompliziert und direkt vor Ort über ihr Mobiltelefon abrufen. Die Inhalte des „Urban-Codes“, der auf der QR-Code-Technologie aufbaut, lassen sich aufgrund ihrer Verknüpfung mit dem mobilen Internet problemlos an zukünftige technische Entwicklungen anpassen. Die vielseitigen Anwendungen eröffnen den Mobiltelefonnutzern umfangreiche Möglichkeiten zur Information und Interaktion – von der Information über Städte, Regionen und ihre Sehenswürdigkeiten über das Erlebnis virtueller Stadtrundgänge und kultureller Besonderheiten bis hin zu Partizipationsprozessen in Planungsfragen.

Im Gegensatz zu den späten 1990ern, in denen noch keine digitalen Inhalte für die Internetpräsenz von Städten und Gemeinden vorhanden waren und diese Inhalte erst erarbeitet werden mussten, ist die Adaption der verfügbaren Informationen auf mobile Endgeräte heute hingegen mit relativ wenig Aufwand verbunden. Einige Blogdienste und Content Management Systeme optimieren sogar automatisiert Inhalte für die mobile Anwendung. Mobile Informationssysteme sollen auch nicht die traditionelle Übermittlung von Daten ersetzen, sie stellen ein weiterführendes Angebot dar, einen neuen Distributionskanal, der eine andere

Klientel anspricht. Diese Form der Vermittlung von Inhalten sollten als Chance, nicht als „technische Last“ empfunden werden.

Mobility barriers in urban transport for the sight or hearing impaired: Solutions help all passengers

Elmar Fürst

(Dr. Elmar Fürst, Institute for Transport and Logistics Management, WU Vienna, Nordbergstr. 15, 1090 Vienna, Austria, elmar.fuerst@wu.ac.at)

1 ABSTRACT

People with visual or hearing impairments represent a significant part of the population. Using public transport services they have to overcome numerous specific problems and obstacles. Quite often they are not even recognized as a group for themselves with special needs and demands but rather mistaken for blind and deaf people. Taking into account that mobility barriers for these groups are completely different, this situation, of course, is not acceptable.

In order to reveal the most common and most hindering specific problems people with sight and hearing impairments are confronted with and to collect proposals to solve them, the Institute for Transport and Logistics Management of the WU Vienna conducted a qualitative short-study based on interviews with persons directly concerned, their representatives, authorities and transport companies as well as on discussions in related internet-fora respectively. Problems at stops and stations, in vehicles, general mobility problems and public perception were taken into account.

Thus the barriers detected and the related solutions proposed were rated according to their technical and financial feasibility as well as to the utility gain for the passengers concerned. It can be shown that numerous measures could be realised at low or even no cost at all as many problems are merely resulting from a lack of awareness, empathy or insufficient training only. Furthermore the implementation of several measures would not only improve access to public transport for the two specific groups but for almost all passengers.

2 BACKGROUND

For most of us mobility is an important part of our everyday life and partly even regarded as a basic human right. However, there are many people who have to face different barriers concerning their personal mobility, for instance people with walking disabilities, other physical or mental handicaps, deaf and blind persons, but also two groups which are usually not getting appropriate attention, namely people with sight or hearing impairments. These two groups are in the focus of this report.

The two groups represent a significant part of the population and, unfortunately, they are often mixed-up with the blind and deaf although these groups have completely different need and requirement profiles concerning their personal mobility. Since blind people cannot see at all they must replace the sense of sight by using their other senses or by additional support like guide dogs. Visually impaired persons on the contrary rely on their optical sense, but are of course unable to reach the same level of vision as normal-sighted persons. Analogously deaf persons cannot hear at all, whilst hearing impaired can but need auxiliary means to improve their acoustic perceptions.

Thus measures in public transport which are implemented and regarded as useful for the blind or deaf mostly fail to foster the mobility of visually or acoustically impaired persons. Another important point to be taken into consideration is the large size of the two groups of people with visual or acoustic impairments. From a statistical point of view their number exceeds by far the blind or deaf or other groups with limited mobility: However public awareness of their relative importance is low. At this point it is important to stress, that it is not the author's intention to set the different groups against each other or to achieve a redirection of funds. The intention is rather to increase the sensitivity for the affected groups, to identify problems and to show ways how to solve them in order to significantly improve the mobility of visually and acoustically impaired persons eventually.

3 DEFINITION

Before the problems and related solutions for sight and hearing impaired persons can be discussed in detail, it is important to delimit to a certain extent the field of interest.

From a medical point of view the delimitation for visual impairments is based on the visual acuity (visus cum correctione, v.c.c; 1.0 = 100% is the average normal eyesight) where a range from 30% down to 10%

acuity can be seen as (moderately) impaired vision and the range from 10% to 2% as severely impaired. Oftentimes the visual field loss is also used to determine the degree of the impairment.

Referring to the WHO International Classification of Diseases (ICD-10) from 2007 visual disturbances and blindness can be found in the groups H53-H54. Table 1 gives the classification of severity of visual impairment which is included in the ICD-10 at the end of the groups H53-H54:

Category of visual impairment	**Visual acuity with best possible correction**	
	Maximum less than:	**Minimum equal to or better than**
1	6/18	6/60
	3/10 (0,3)	1/10 (0,1)
	20/70	20/200
2	6/60	3/60
	1/10 (0,1)	1/20 (0,05)
	20/200	20/400
3	3/60	1/60 (finger counting at 1 metre)
	1/20 (0,05)	1/50 (0,02)
	20/400	5/300 (20/1200)
4	1/60 (finger counting at 1 metre)	Light perception
	1/50 (0,02)	
	5/300	
5	No light perception	
9	Undetermined or unspecified	

Table 1: Classification of severity of visual impairment recommended by a WHO Study Group on the Prevention of Blindness, Geneva, 6-10 November l972. (WHO Technical Report Series No. 518, 1973) The term "low vision" in category H54 comprises categories 1 and 2 of the table, the term "blindness" categories 3, 4 and 5, and the term "unqualified visual loss" category 9. If the extent of the visual field is taken into account, patients with a field no greater than 10 o but greater than 5 o around central fixation should be placed in category 3 and patients with a field no greater than 5 o around central fixation should be placed in category 4, even if the central acuity is not impaired. (Source: World Health Organization: http://apps.who.int/classifications/apps/icd/icd10online/)

Level 1 could be referred to as “moderate” visual impairment, level 2 as “severe” visual impairment This article is focusing mainly on persons with a moderate low vision (acuity 0.3 to 0.1) though, however it has to made clear at this point, that basically anybody with a visual acuity lower than 1.0 which cannot be corrected by spectacles or contact lenses could be considered as visually impaired. This is a crucial point as measures taken in public transport for people subject to the rather narrow definition above shall also help all other passenger with an acuity of less than 100%.

Hearing impairments (included in chapter VIII, groups H60ff. of the ICD-10) can be measured through many different means. The most commonly used method is the “hearing distance”-test. According to the guidelines the hearing distance is the distance in which at least half of the words spoken by the examiner are repeated correctly by the test person. Another important test to determine the degree of impairment is the quantitative measure of the hearing ability according to Boenninghaus u. Röser (1958). In this test two tables are used, one for the hearing distance for whispered and normal spoken words and the other for the results of an audiometric measurement, to define the degree of acoustic impairment. This article focuses on the group with a medium level of hearing impairment.

There are no detailed official statistics which could help to determine the exact size of the two groups in the population. For Austria, in 2007 a dedicated module focusing on persons with impairments was included in the microcensus by Statistics Austria. According to this survey roughly 3.8% of the Austrian population suffer from a persisting visual and about 2.5% from a persisting acoustical impairment respectively. In both groups the majorities show medium to heavy impairments; women make up the larger parts.

4 METHOD

In a qualitative short study the Institute for Transport and Logistics Management of the WU (Vienna University of Economics and Business) mobility barriers for the sight and hearing impaired have been addressed. On the basis of a literature research a survey guideline with several open questions to be used in structured expert interviews was developed. The interviews were restricted to Austria though, but the results might still be transferable to other countries.

To get a comprehensive picture not only persons directly affected by a sight or hearing impairment were interviewed but also their representatives in associations or support groups as well as public authorities and responsible persons from transport companies (Table 2).

Interview Partners	Count
Visually impaired Persons	11
Acoustically impaired Persons	5
Associations	3
Transport companies	4
Authorities	2

Table 2: Persons interviewed

Furthermore dedicated threads were opened in internet-based discussion fora in order to reach also those affected persons who are not mobile (Table 3).

Table 3: List of internet-fora

Table 4 shows the basic structure of the interviews which were slightly adapted according to the respective interview partner.

Subjects
Estimation of the size of seeing and hearing impaired persons in the population
Mobility problems of the affected groups
How are problems detected?
Development of possible solutions
Ways of taking specific measures

Table 4: Contents of the interviews

The interviews were transcribed and detailed lists of the detected problems of hearing and seeing impaired people with regard to their mobility were compiled. The possible solutions raised by interview partners were also included. During several project meetings categories were defined and the problems and solutions were classified accordingly. Furthermore the technical feasibility, the relevant costs and the utility gain for the affected were assessed.

To depict the results a rating system was introduced based on a 5 point scale where a higher score denominates a better result. As an example one point on the “cost-scale” of the following tables would represent high investments whilst five points would mean little to no costs at all.

5 RESULTS

The following tables show the results of the short study. To allow easier understanding the problems and solutions have been assigned to the following areas: “stops and stations”, “vehicles”, “other/general mobility problems”, and “public awareness”.

5.1 Stops and stations

The following table depicts commonly occurring problems at stations and the surrounding area.

Identified problem	Possible solution	Technical feasibility	Related Costs	Utility gain	Mainly for
Complex use of ticket machines	Possibility to increase the size of text.	☺☺☺☺	☺☺☺☺	☺☺☺☺	Sight impaired
	Voice output on demand	☹☹	☹	☺☺☺☺☺	Sight impaired
Readability of timetables	Timetables placed not too high – legibility has to be guaranteed (e.g. using reading aids, loupes, etc.)	☺☺☺☺	☺☺☺☺	☺☺☺☺	Sight impaired
	Pre-printed timetables in large print	☺☺☺☺☺	☺☺☺☺	☺☺☺☺	Sight impaired
	Decrease of distance between glass and timetable to allow reading with low vision aids	☺☺☺☺☺	☺☺☺☺	☺☺☺☺	Sight impaired
	Use of antireflection glass for showcases	☺☺☺☺	😐😐😐	☺☺☺☺	Sight impaired
Displays	Extended information on displays	☺☺☺☺	☺☺☺☺	☺☺☺☺☺	Both groups
	Use of contrasting colours	😐😐😐	😐😐😐	☺☺☺☺	Sight impaired
	Increase of font size	😐😐😐	☺☺☺☺	☺☺☺☺☺	Sight impaired
	Decreased height of mounted displays to eye-level and increased accessibility	☺☺☺☺	☺☺☺☺	☺☺☺☺	Sight impaired
Incomprehensible announcements at stations	Show announcement on displays and info-screens (“two-senses-principle”)	☺☺☺☺	☺☺☺☺	☺☺☺☺☺	Both groups
	Use of induction technology, especially at larger stations	☹☹	☹	☺☺☺☺☺	Hearing impaired
	Information per SMS upon requests	😐😐😐	😐😐😐	☺☺☺☺	Both groups
	Announcements available through MMS	😐😐😐	😐😐😐	☺☺☺☺	Both groups
	Free hotline with tape-service for important information	☺☺☺☺	☺☺☺☺	☺☺☺☺	Both groups
	Clear, slow and understandable tape-records and announcements	☺☺☺☺☺	☺☺☺☺☺	☺☺☺☺☺	Both groups
Inadequate guiding systems	Installing additional guiding systems	😐😐😐	☹	☺☺☺☺	Sight impaired
	Purpose-check of existing guiding systems by affected persons	☺☺☺☺☺	☺☺☺☺	☺☺☺☺	Sight impaired
	Including affected in planning process	☺☺☺☺☺	☺☺☺☺	☺☺☺☺	Both groups
	IT-based guiding systems (web-based, cellular)	😐😐😐	☹	☺☺☺☺	Both groups
Multi vehicle stations	Clear splitting of station areas for different lines	☺☺☺☺☺	☺☺☺☺	☺☺☺☺	Sight impaired
	Clearly visible display of the line arriving next	☺☺☺☺	😐😐😐	☺☺☺☺	Both groups
	Announcements of approaching vehicle	☺☺☺☺☺	☺☺☺☺	☺☺☺☺	Sight impaired
Station signposting	Bigger font sizes	☺☺☺☺	😐😐😐	☺☺☺☺☺	Sight impaired
	Use of clearly visible markings, paying attention to contrasts, height and place	☺☺☺☺	😐😐😐	☺☺☺☺	Sight impaired
Stations in rural areas	Safe footpaths	☹☹	😐😐😐	☺☺☺☺	Both groups
	Speed-limitations for other traffic in the station area	☺☺☺☺	☹☹	☺☺☺☺	Both groups
	Relocation of stations aside from main roads	😐😐😐	☹	☺☺☺☺☺	Both groups
Specially trained staff	Especially at central stations more support personnel	☺☺☺☺	☹	☺☺☺☺	Both groups
Entering and leaving vehicles	No traffic on lanes between vehicle and station while dis-/embarkation	😐😐😐	☺☺☺☺	☺☺☺☺	Both groups
Information at stations	Continuous information through Bluetooth or IR	☺☺☺☺	😐😐😐	☺☺☺☺☺	Both groups
	Downloadable web-based route-planning and on-trip use	😐😐😐	☹	☺☺☺☺☺	Both groups
Elevators at stations	Emergency-button for hearing impaired persons	😐😐😐	☹☹	☺☺☺☺	Hearing impaired
	Acoustic information	😐😐😐	☹	☺☺☺☺	Both groups

Table 5: Problem identification and possible solutions for the stops and station area

The main problem areas identified were missing guiding systems particularly for sight impaired persons, whereas hearing impaired people often had problems with the elevators at stations and with the service

hotlines in a case of emergencies. Other regularly mentioned problem areas were the signposting and the announcements at stations.

5.2 Vehicles

The second area of interest were the problems within the means of transport as shown by the following overview.

Identified problem	Possible solution	Technical feasibility	Related Costs	Utility gain	Mainly for …
Use of ticket machines on vehicles	Voice output on demand	☹☹	☹	☺☺☺☺☺	Sight impaired
	Bigger font size	☺☺☺☺	☺☺☺☺	☺☺☺☺	Sight impaired
Legibility of network plans	Plans at eye-level, focus on legibility	☺☺☺☺	☺☺☺☺	☺☺☺☺	Sight impaired
	Driver has plans in large print	☺☺☺☺	😐😐😐	☺☺☺☺	Sight impaired
	Network plans in large print available	☺☺☺☺	☺☺☺☺	☺☺☺☺	Sight impaired
Displays on vehicles	Show announcements on displays (“two-senses-principle”)	😐😐😐	😐😐😐	☺☺☺☺☺	Both groups
	Check used colours with the affected	☺☺☺☺	☺☺☺☺	☺☺☺☺	Sight impaired
	Font size easily readable	☺☺☺☺	☺☺☺☺	☺☺☺☺☺	Sight impaired
Quality of announcements	Optical display of announcements	😐😐😐	😐😐😐	☺☺☺☺☺	Both groups
	Use of induction-technology	☹☹	☹	☺☺☺☺☺	Hearing impaired
	On-demand information about next station (Bluetooth)	☺☺☺☺	😐😐😐	☺☺☺☺	Both groups
	SMS- or MMS-queries	😐😐😐	😐😐😐	☺☺☺☺	Both groups
	Free hotline with tape-service for important information	☺☺☺☺	☺☺☺☺	☺☺☺☺	Both groups
	Take employees for test drives to let them perceive the comprehensibility and quality of announcements	☺☺☺☺☺	☺☺☺☺	☺☺☺☺	Both groups
	Pronunciation, clarity and speed of announcements and tape-records	☺☺☺☺☺	☺☺☺☺☺	☺☺☺☺☺	Both groups
Automating	Mobility training for affected supported by transport companies	☺☺☺☺	😐😐😐	☺☺☺☺	Both groups
Distance vehicle – pavement	Drivers to stop close to pavement	☺☺☺☺	☺☺☺☺	☺☺☺☺	Sight impaired
	Use of low-floor-vehicles	☺☺☺☺	☹	☺☺☺☺☺	Both groups
Information in the vehicle	Device to be informed about the route, the next stop etc. Upon request	☹☹	☹☹	☺☺☺☺☺	Both groups
	On-demand general information via bluetooth	☺☺☺☺	😐😐😐	☺☺☺☺☺	Both groups
	Downloadable web-based route-planning and on-trip use	😐😐😐	☹	☺☺☺☺☺	Both groups
Doors	Large tactile door opening buttons	☺☺☺☺	😐😐😐	☺☺☺☺	Sight impaired

Table 6: Problem identification and possible solutions for vehicles

The main problem for sight impaired persons was the small print of network plans on the vehicles which forces them to use low vision aids like loupes. On the other hand many of these plans are placed at the roof of the vehicle which inhibits the use of such tools. A simple and cost effective solution would be the printing of network plans in bigger fonts and attaching them at eye-level.

Hearing impaired persons often criticize the bad quality or even the lack of the announcements in the vehicles. Not only are they regularly spoken too fast but also quite often incomprehensibly. The visually impaired also expressed problems with the announcements as they are often unable to read the name of stations and therefore rely on it in order to know where to get off. Thus the use of the two-senses-principle, which means that information should always be available optically and acoustically, should definitely be the standard.

5.3 General mobility problems

Some other – rather general – mobility problems could further be identified as shown in table 7.

Identified problem	Possible solution	Technical feasibility	Related Costs	Utility gain	Mainly for …
Information about transport on the internet	Possibility to increase the size of fonts and inverted colours	☺☺☺☺	☺☺☺☺	☺☺☺☺☺	Sight impaired
	On-demand voice output of site	☺☺☺☺	😐😐😐	☺☺☺☺☺	Sight impaired
Road signs as barriers	Place on gantries	☺☺☺☺	☹☹	☺☺☺☺	Sight impaired
	Use of max. permiss. height (2.2 m)	☺☺☺☺☺	☺☺☺☺	☺☺☺☺	Sight impaired
	Use of protective coatings	☺☺☺☺	😐😐😐	☺☺☺☺	Sight impaired
Bollards, hydrants, advertising pillars, green spaces, cordons	Use signal colours	☺☺☺☺	☺☺☺☺☺	☺☺☺☺	Sight impaired
	Double cordons with connecting elements	☺☺☺☺	😐😐😐	☺☺☺☺	Sight impaired
	Replace by fixed railing	☺☺☺☺	😐😐😐	☺☺☺☺☺	Sight impaired
Construction site security	At least to crossbars	☺☺☺☺	☺☺☺☺	☺☺☺☺	Sight impaired
	Signal colours for scaffoldings	☺☺☺☺	☺☺☺☺	☺☺☺☺	Sight impaired
	Solid barriers at building pits	☺☺☺☺	😐😐😐	☺☺☺☺	Sight impaired
	Barriers with construction fences	☺☺☺☺	😐😐😐	☺☺☺☺☺	Sight impaired
Weather conditions	Stricter regulations for snow removal and gritting	😐😐😐	☹☹	☺☺☺☺	Both groups
	Fixed cordons when danger of roof avalanches	☺☺☺☺	😐😐😐	☺☺☺☺	Both groups
	Tree and bush cutting	☺☺☺☺	😐😐😐	☺☺☺☺☺	Both groups
Railroad crossings without gates	Installation of gates	😐😐😐	☹	☺☺☺☺☺	Both groups
	Tactile floor markings	😐😐😐	☹	☺☺☺☺☺	Sight impaired
	Flashlights in the floor before train arrives	😐😐😐	☹	☺☺☺☺☺	Both groups
	Tow away parked vehicles	☺☺☺☺	☺☺☺☺☺	☺☺☺☺	Sight impaired
	Restaurant menu tables on the wall, restaurant tables not on the pavement	☺☺☺☺	☺☺☺☺	☺☺☺☺	Sight impaired
Other obstacles on pavement	No placards/advertisements covering signs	☺☺☺☺	☺☺☺☺	☺☺☺☺	Sight impaired
	Removal of different levels, gaps	☺☺☺☺	☹☹	☺☺☺☺	Both groups
	Tactile and optically contrasted markings	☺☺☺☺	☹☹	☺☺☺☺	Sight impaired
Cycle tracks	Involvement of seeing and hearing impaired people	☺☺☺☺☺	☺☺☺☺	☺☺☺☺☺	Both groups
	Distinct separation by advertisements or similar	☺☺☺☺☺	☺☺☺☺	☺☺☺☺☺	Sight impaired
Architecture	Easily visible handrails	☺☺☺☺☺	☹☹	☺☺☺☺	Sight impaired
Glass walls	Use of non-transparent glass	☺☺☺☺	☺☺☺☺	☺☺☺☺	Sight impaired
	Use of safety glass	☺☺☺☺	☹☹	☺☺☺☺	Sight impaired

Table 7: Identification and possible solutions for general mobility problems

In this area railroad crossings without gates were identified as a predominant problem for both groups. Particularly crossings in rural areas are not equipped with optical signals and are therefore dangerous for acoustically impaired persons. In Austria it could already be achieved at least, that an extra sign has to be placed at such crossing requesting people to pay particular attention to acoustic signals of approaching trains.

Another very problematic topic were the security measures around building sites, where sight impaired persons often come into danger because of missing or inappropriate barriers that would prevent them from entering such places. Adequate safety measures would not necessarily cost more than the ones in use but significantly increase the safety for impaired persons.

Many other problem areas could be identified, like glass doors or cycle lanes where accidents leading to severe injuries are likely. Again quite cheap solutions could allow enormous improvements.

5.4 Public awareness

The lack of awareness and empathy for sight and hearing impaired persons as well as insufficient training of drivers, service staff and planners is probably the most important and fundamental source of mobility problems of the groups concerned. This is partly due to the fact that they cannot be easily recognized at first sight as having special mobility needs and requirements. The following problems could be detected.

Identified problem	Possible solution	Technical feasibility	Related Costs	Utility gain	Mainly for …
Inadequate training of staff and planners	Special courses focusing on different disabilities and impairments for architects, planners, drivers and other staff of transport companies	☺☺☺☺☺	☺☺☺☺☺	☺☺☺☺	Both groups
	Lobbying by associations	☺☺☺☺☺	☺☺☺☺	☺☺☺☺	Both groups
	Brochures, information material	☺☺☺☺	☺☺☺☺	☺☺☺☺	Both groups
Unawareness of specific problems	Improve publicity of related information platforms	☺☺☺☺	☺☺☺☺☺	☺☺☺☺☺	Both groups
Research & Development	Include affected people in research & development	☺☺☺☺	☺☺☺☺☺	☺☺☺☺☺	Both groups
Lack of awareness and empathy	Information campaigns	☺☺☺☺☺	😐😐😐	☺☺☺☺☺	Both groups
	Special events like "Dialog im Dunkeln"	☺☺☺☺	😐😐😐	☺☺☺☺	Both groups

Table 8: Problem identification and possible solutions within the field of public awareness

A need for increasing public awareness for the two groups was one of the major topics raised by affected persons and their representatives both in the interviews and in the internet-discussions. Many people simply do not know about the large size of the two groups and their specific needs and requirements concerning their mobility. This information deficit could be overcome at relatively low costs.

Furthermore it would be useful to include sight or hearing impaired persons directly or their representatives in all major planning processes for new public transport buildings or vehicles and to take their demands into account right from the beginning.

6 CONCLUSIONS AND IMPLICATIONS FOR FURTHER RESEARCH

Sight and hearing impaired persons are two large groups of the population who – each for themselves – have to face specific mobility barriers. It is problematic, that they are often not seen as individual groups but are mistaken as blind or deaf. This inadequate perspective seems to be quite common among transport companies and authorities.

The interviews have shown that in the past too little has been done to improve the mobility of the sight and hearing impaired, but also that the situation has slightly improved over the last years.

Transport companies would like to have clearer and more obvious guidelines on how to design vehicles and stations in an appropriate way. Dedicated guidelines or standards as well as support from official authorities would be regarded as useful.

The most fundamental result was, however, that as a first step public awareness of the two groups and their problems needs to be urgently raised.

The detailed results of the short study show many aspects and problems for visually or acoustically impaired and proposals for their solution. It could be shown, that many measures would not even require large investments but merely the willingness to put oneself in the position of the persons who have to overcome mobility barriers. Thus it becomes evident, that the most common problem is ignorance and rarely scarce funds.

Therefore it seems as if the two groups still do not attract sufficient attention, otherwise solutions which could be taken at low costs but yield significant improvements would already have been realised. Taking such measures would clearly be economically beneficial for transport companies as many people, currently limited in their mobility, would use public transport services again resulting in higher passenger counts and revenues. Moreover the general attractiveness of public transport would rise which helps all passengers to get along with the services provided.

The short-study presented in this article can be seen as an initial step to treat related problems from a research perspective. However, there is a clear need for further research, aiming at a clear definition of specific demands for the two groups and at the development of common standards which can be applied by transport companies and technical suppliers. Recently, a large-scale research project related to these goals has been launched in the framework of the ways2go programme initiative and will be funded by the Austrian

Federal Ministry of Transport, Innovation and Technology (BMVIT) and the Austrian Research Promotion Agency (FFG).

The project, called “MoViH” (Mobility of the sight and hearing impaired in public transport) comprises in detail the following objectives:

- Clear identification and description of special needs and requirements
- Evidence on actual and desired mobility
- Identification of factors enhancing and hindering mobility
- Determination of intrinsic mobility barriers
- Development of new solutions and measures
- Detection of potentials for improvements of existing solutions
- Analyses of the gap between the transport companies’ and the sight and hearing impaired people’s points of view
- Economic assessment of newly developed measures
- Development of a tool for the evaluation of measures (“efficiency indicator”)
- Creation of an internationally applicable standard to be used by public transport companies
- Raise of general awareness by sharing information and dissemination of results

The project partners (universities, associations, transport companies and technical suppliers) hope that the new project will help to better understand the problems of the sight and hearing impaired and to improve their access to public transport services. Any measure taken for these people, however, will not only help them but the total of all passengers and hence make public transport more attractive.

1 ABSTRACT

Preparation of spatial plan is response to the objectives, which are often in conflict. Planners decide to search for optimal solutions, where the optimum is usually a subjective assessment of meeting the set of goals and criteria. Given that the land is limited resource, it raises more the question of sustainability of life on Earth and the necessity of rational, scientifically-based land planning purposes. This study developed a methodology for multi-criteria land use classification based on a set of relevant factors and geographical parameters, using the AHP method (Analytical Hierarchy Process) for multi-criteria decisions and GIS tools for creation, storage, analysis and operations of the data.

The developed methodology is tested to solve the problem of evaluation and classification of land for the building construction, using data related to the area of Tuzla Municipality. The result of this research in a general sense is a methodology for multi-criteria land use analysis in GIS needed for spatial planning. In the specific sense a result of this research is the map of categorized land for building construction in the municipality of Tuzla, which clearly indicates the spatial potentials and constraints. Thematic maps, obtained as a result of applying the presented methodology allows planners make rational and strategically important decisions regarding the allocation of land purposes, and planning for sustainable development.

2 INTRODUCTION

As the land is very limited resource nowday, it is important to recognize its potential, and optimize its use. Due to the complex needs and a large number of criteria (environmental, economic, sociological, natural) decision-makers needs to use techniques of multi-objective planning and multi-criteria analysis in many social activities related to land, especially in the field of planning of spatial organization [4].

Because of the rapid urbanization process frequently arises the need for space planning purposes with emphasis on building high-rise buildings, and construction of urban infrastructure for housing, work and a variety of supporting activities of the population. Due to the large number of specific criteria (geotechnical, environmental, construction, urban and others), which need to be considered in this planning, the application of multi-criteria analysis methodology can have a significant impact on the quality, speed and cost of the planning. It will primary assist in valorization of land which serves as the ground for the planning. Efficient approach, which involves the application of tools for geospatial analysis (GIS) methods and techniques of multi-criteria system analysis, will enable spatial planners to solve easier and faster the problem related to land use planning for the construction of high-rise buildings and associated infrastructure [10]. This approach can be applied in the framework of special studies (evaluation of land use for the construction of high-rise buildings), which would give answers to many questions of importance for the spatial plan. Some of the issues which correlate with this research area are the following:

- identification of the land with natural and technological predispositions for building high-rise buildings,
- creation of the optimal model for the valorization of land which indicates cost effectiveness of investments and
- compliance with the measures and objectives of urban development according to international conventions.

3 APPLICATION OF MULTI-CRITERIA ANALYSIS TO URBAN LAND-USE PLANNING

3.1 A brief overview of the methodology

The methodology for the evaluation and classification of land for the construction of high-rise buildings consists the following 4 stages (Fig. 1):

- 1) Identification of multi-criteria decision making elements involves the identification of objective synthesis model. As the objective model in the study it is identified environmental synthesis model where weights are assigned considering environmental criteria.
- 2) Criteria weights definition means evaluation of weights assigned to criteria (factors) according to the target synthesis model.

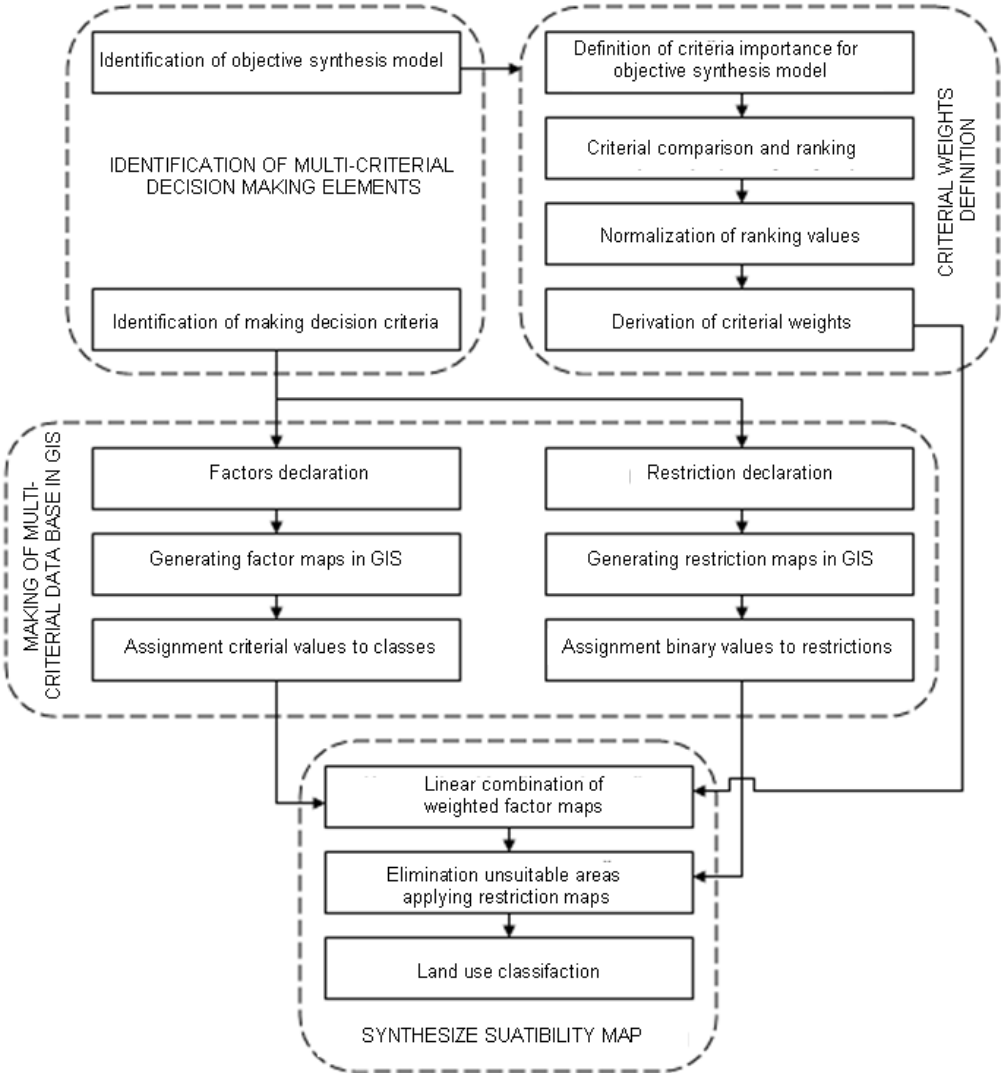

Fig. 1: Key stages in the procedure of land use classification for construction of high-rise buildings

- 3) Making of multi-criteria database in GIS is implemented generating factor maps and restriction maps, and assigning criterial and attribute values to each class of factor and restriction maps.
- 4.) Synthesize suitability map is realized through the analysis of linear combination weigthed factor maps, the elimination of unsuitable areas and land use classification. Overview of certain classes of land (with or without restrictions) is usually represented by area balances table.

3.2 Land suitability map

In the process of spatial planning a digital land suitability map is a graphical spatial representation of land use for certain use [5]. This map can be generated as thematic map in GIS, based on appropriate model of multi-criteria analyses [2]. Multi-criteria analysis includes different criteria that determines the geological, geomorphologic, environmental and other characteristics of land. Land suitability map for a particular purpose (e.g. the construction of high rise-buildings) contains the set of arranged and classified values (assigned to cells) by all established criteria. This map demonstrates the spatial distribution of classified abilities. The accuracy of geospatial analysis and performance of the used analytical algorithms depends very much on selected grid resolution [3]. The spatial framework with grid resolution (cell size) of 10x10 m is used in this study.

3.3 Criteria for evaluation of land suitability

Selection of the criteria is very sensitive task and it should take into account those aspects that significantly affect the selection of sites for construction facilities and that are relevant to the preservation of the environment (environmental syntheses model) [1]. As a result of the selection process within the framework of this study the following criteria and restrictions were identified [6]:

- 1. Technical and technological aspects:
  - 1.a. land accessibility,
  - 1.b. slope of the land surface
- 2. Security aspects:
  - 2.a. geotechnical suitability,
  - 2.b. influence of terrain sinking,
  - 2.c. restrictions related to the impact of landslides
- 3. Environmental aspects:
  - 3.a. restrictions in terms of already occupied areas (farmland, forest area, public transport area, water surface, surface and underground mines area)
- 4. Urban-ambiance aspects:
- 4.a. aspect of terrain.

3.4 Weights assignment procedure

In this study the AHP (analytic hierarchy process) method is used to weight and compare the criteria. It is based on creating a matrix of pairwise comparisons. In this technique, the weight can be defined using the basic eigen-vectors of a square reciprocal matrix of pairwise comparisons between the criteria. These comparisons are considering the relative importance of two criteria used to determine the suitability of a defined objective. Ratios are defined by continuous scale (Fig.2) of nine points (degrees).

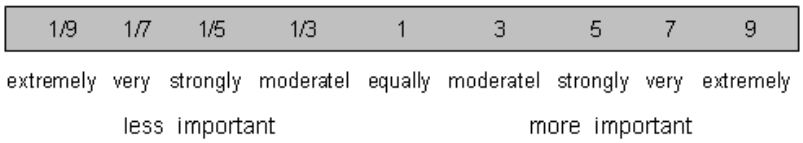

Fig. 2: The continuous rating scale used for the pair wise comparison of factors in the multi-criteria evaluation

Definition of weight includes comparison of every possible pair of criteria by entering scores (range) in a matrix of pairwise comparison (Table 1). As a good approximation for the calculation procedure of eigen-vectors can be used the sum of weights for each column and determination of the average value for each entry in all columns [8]. According to this procedure it is carried out criteria weighting in accordance to their importance as described in Table 1.

Factors	Land Accessibility	Terrain Slope	Geotechnical Usability	Terrain Sinking	Terrain Aspect
Land Accessibility	1	1/5	3	5	1/7
Terrain Slope	5	1	5	7	1/3
Geotechnical Usability	1/3	1/5	1	3	1/7
Terrain Sinking	1/5	1/7	1/3	1	1/9
Terrain Aspect	7	3	7	9	1
Sum of weights	**13.53**	**4.54**	**16.33**	**20**	**1.72**

Table 1: Sum of weights calculation

The total value of the sum weights for all columns is 56.12. Dividing this value with the sums for each criteria we got a weight of individual criteria (Table 2).

Factors	Normalized weights
Land Accessibility	0.24
Terrain Slope	0.08
Geotechnical Usability	0.29
Terrain Sinking	0.36
Terrain Aspect	0.03
Σ	**1.00**

Table 2: Calculation of average (normalized) weights

3.5 Creation of factor maps

Multi-criteria evaluation is realized using cartographic algebra on factor (criteria) maps in the GIS [11]. The following discussion describes the steps in the procedure of multi-criteria evaluation of land use for planning high-rise buildings in the municipality of Tuzla. The classification of terrain hights, and creating maps for the exposure factor (terrain aspect) and land slopes uses digital terrain model, which is obtained by inverse distance weighting interpolation of a set of elevation points (Fig. 3) [9]. On the basis of determined parameters (rank of horizontal and vertical angles) for each class of orientation and inclination in GIS, the factor (criteria) maps are created (Fig. 4). Assignment of criteria values of classes is automatic process that realizes by grid query (for the selection of class and entering the same attributes for all cells of the same class).

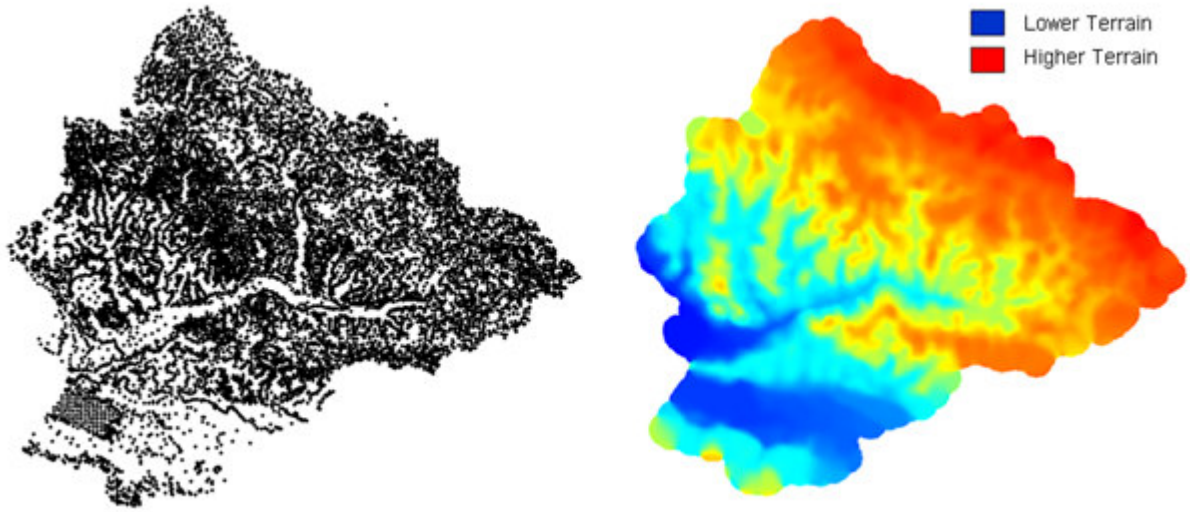

Fig. 3: Creating a DTM of Tuzla municipality (right) from a set of vertical points (left)

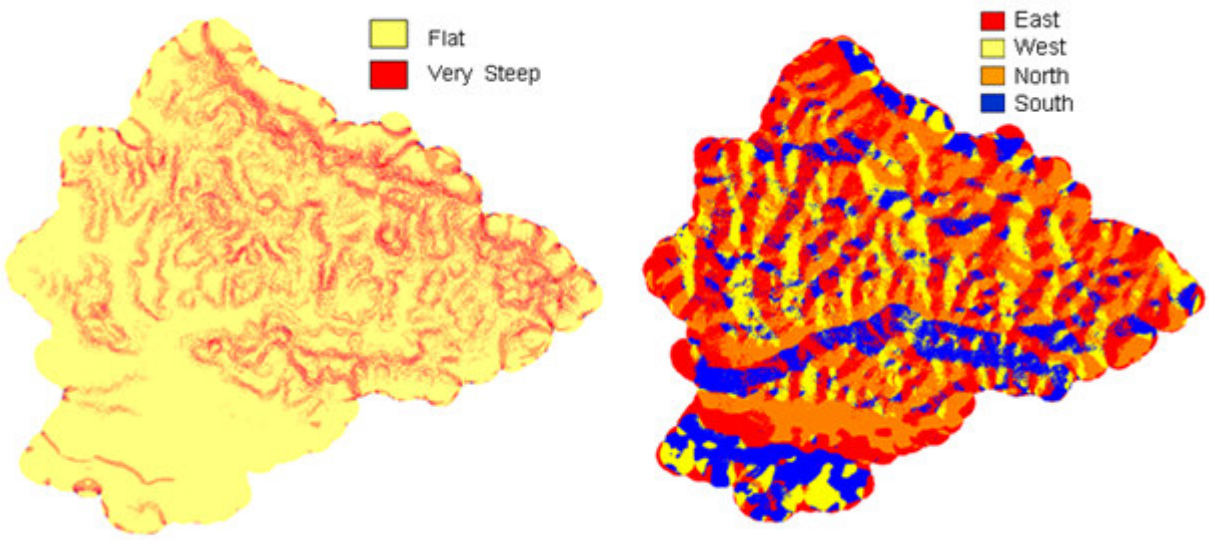

Fig. 4: Creating a land slope (left) and terrain aspect factor maps (right)

Assignment (scoring) of criterial values for certain classes of terrain slope and aspect criteria is described in Table 3. Entering chronometrical values over XYT file leads to the factor maps of land accessability (Fig. 5).

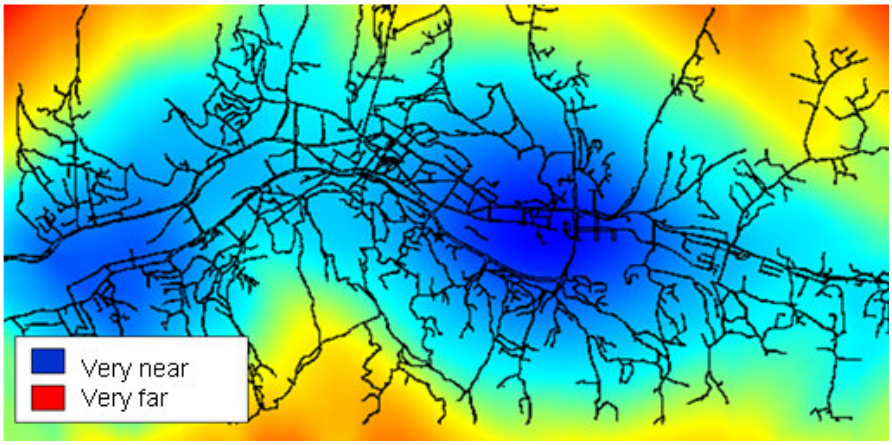

Fig. 5: Factor map of land accessibility

Assignment (scoring) of criterial values for certain classes of land accessabilty criteria is described in Table 3. Fig. 6 shows factor map of geotechnical zones created by existing digital geotechnical map of Tuzla urban area.

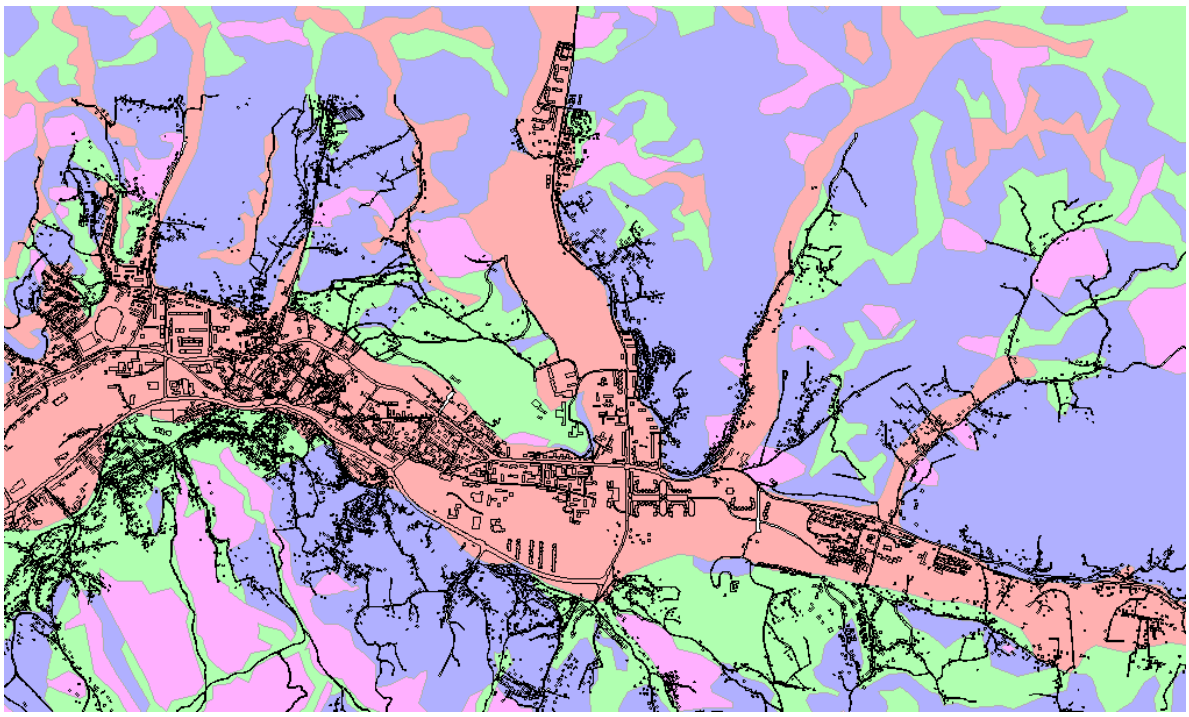

Fig. 6: Factor map of geotechnical zones: zone 1 (red color), zone 3 (green color), zone 3 (blue color), and zone 4 (purple color)

Assignment (scoring) of criterial values for certain classes of geotechnical sutability criteria is described in Table 3. As a criteria that affects the suitability of land for the construction of buildings in terms of terrain sinking it is used map with zones (Fig. 7) based on the geodetic observation intensity of surface deformation phenomena (caused by salt underground exploitation).

Assignment (scoring) of criterial values for certain classes of terrain sinking criteria is described in Table 3. Method of evaluation for each class is based on risk degree of surfice deformation in the period of terrain consolidation [13].

Based on the obtained criteria values (Table 3) and corresponding critera weight (Table 2), the GIS generated thematic map of land suitability for the specific purpose (the construction of high rise-buildings).

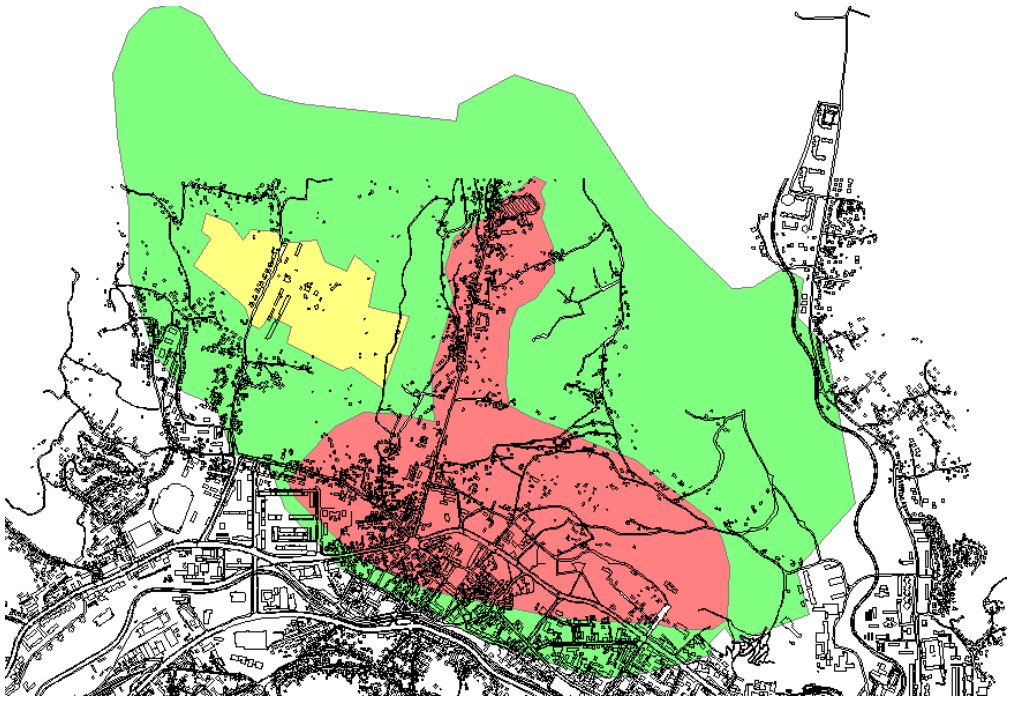

Fig. 7: Factor map of terrain sinking in Tuzla urban area: 1st zone (red color) , 2nd zone (yellow color), and 3rd zone (green color)

Terrain Slope Classes	Terrain Slope Description	Terrain Aspect Classes	Terrain Aspect Description	Land Accessibility Classes	Land Accessibility Description	Geotechnical Usability Classes	Geotechnical Usability Description	Sinking Terrain Classes	Sinking Terrain Description	SCORES (1-5)
flat	0-5%	South	135-225°	very near	0-5min	1st zone	very usable	4th zone	no risk	5
small inclination.	5-10%	-	-	near	5-10min	-	-	-	-	4
inclined	10-20%	East/ West	45-135°/ 225-315°	accessible far	10-15min	2nd zone	moderate usable	3rd zone	low risk	3
steep	20-30%	-	-	far	15-20min	-	-	2nd zone	moderate risk	2
very steep	30-45%	North	315-45°	very far	20-30min	3rd zone	less usable	1st zone	high risk	1

Table 3: Criteria values assignment (scoring)

3.6 Land classification for the planning of buildings

To get the final results of multi-criteria analysis it is necessary to perform aggregation of the weighted critera values by factor (criteria) maps and ranking (classification) of the land for a particular purpose. The total value of land for each grid cell is calculated on the basis of the following expression [12]:

$$\upsilon_z = (w_1 f_1 + w_2 f_2 + w_3 f_3 + w_4 f_4 + w_5 f_5 - \upsilon_{\min})/(\upsilon_{\max} - \upsilon_{\min}) \qquad (1)$$

- w_i presents weights for particular criteria (factors) i = 1 .. 5,
- f_i are assigned values (points) per class for the appropriate criteria, and
- $\upsilon_{\max}$ i $\upsilon_{\min}$ are the maximum and minimum value of the land critera value.

Table 4. ranks the values according to which land classification is made for the purpose of building construction.

Category of Area	Description	Rank
extraordinary suitable	area suitable for high buildings (multi-stores with 5 and more stores)	0.75 - 1.00
very suitable	area suitable for smaller buildings (multi-stores up to 5 stores)	0.50 - 0.75
suitable	area suitable for smaller individual buildings (up to 2 stores)	0.25 - 0.50
unsuitable	unsuitable area for buildings	0.00 - 0.25

Table 4: Land use classification for construction of multi-stores buildings

Based on the rank of values it is realized thematization and classification of the total land values in GIS generating map of land sutibility for construction of buildings (Fig. 8). To get the final land use maps it is necessary to apply restrictions which reduces the area with land unsuitable for building. The further discussion describes the approach to the introduction of restrictions in multi-criteria model.

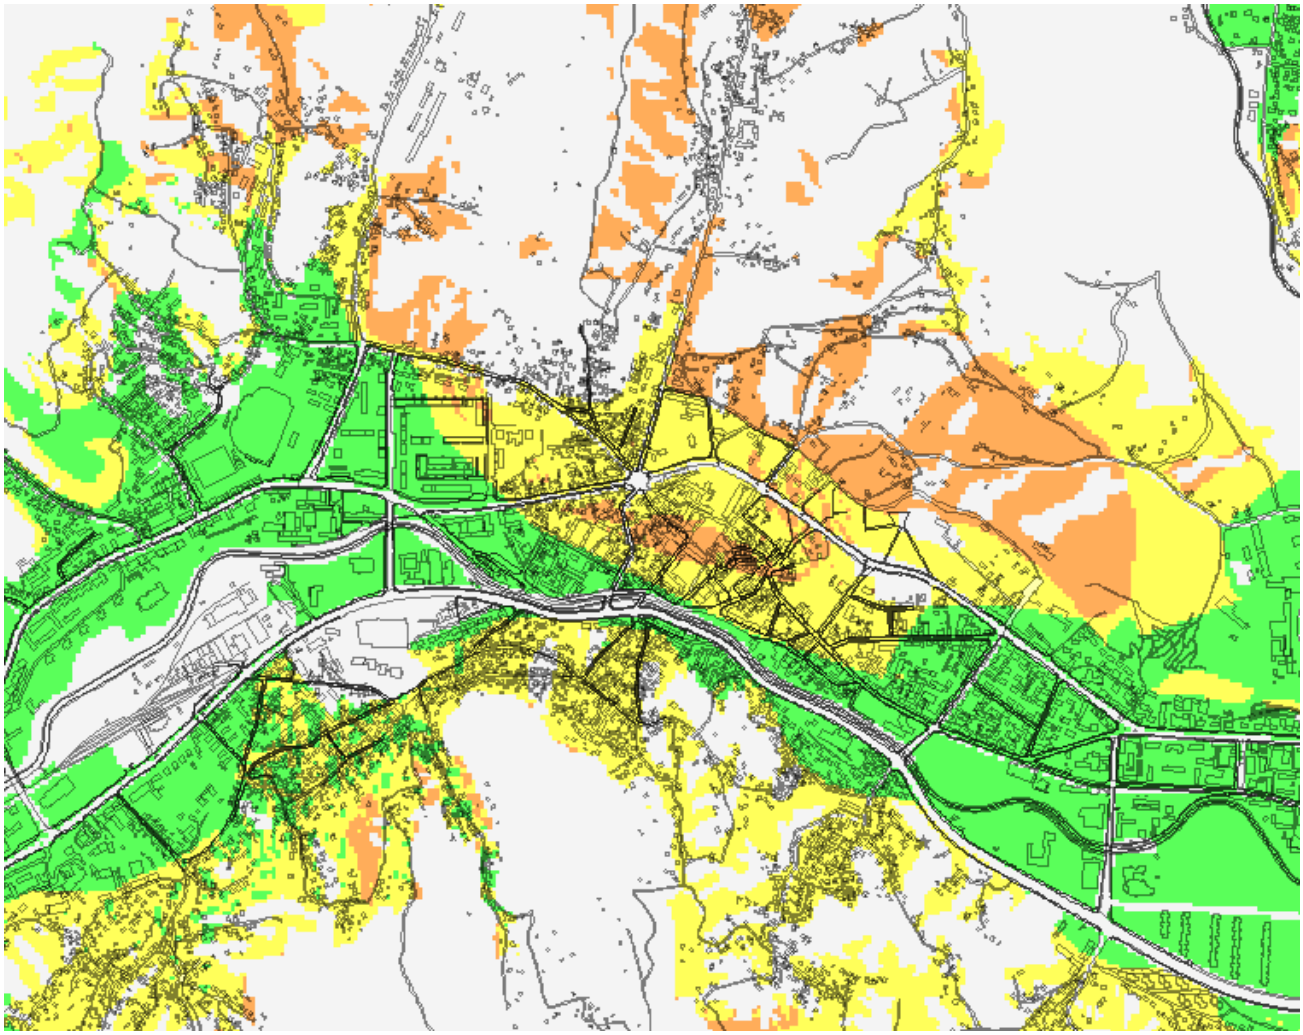

Fig. 8: Multi-criteria land use classification for buildings construction in Tuzla urban area (green – extraordinary suitable, yellow – very suitable, orange – suitable and gray – unsuitable area)

3.7 Application restrictions in multi-criteria model

Restrictions in multi-criteria model are applied as Boolean restrictions [8]. The procedure is reduced to multiplication land suitabilities (total land criteria values calculated by expression 1) and the restrictions according to the following expression:

$$\upsilon_{zo} = \upsilon_z * \Pi o_j \,, \qquad (2)$$

where oj is assigned a binary value for the j-th restriction (0 for elimination areas and 1 for other areas), and Π is the product of considered restrictions. There are the following restrictions applied in the study:

- landslides (active, passive and potential) (Fig. 9) [13],
- forest and agricultural areas (Fig. 10) and
- transportation infrastructure and water areas.

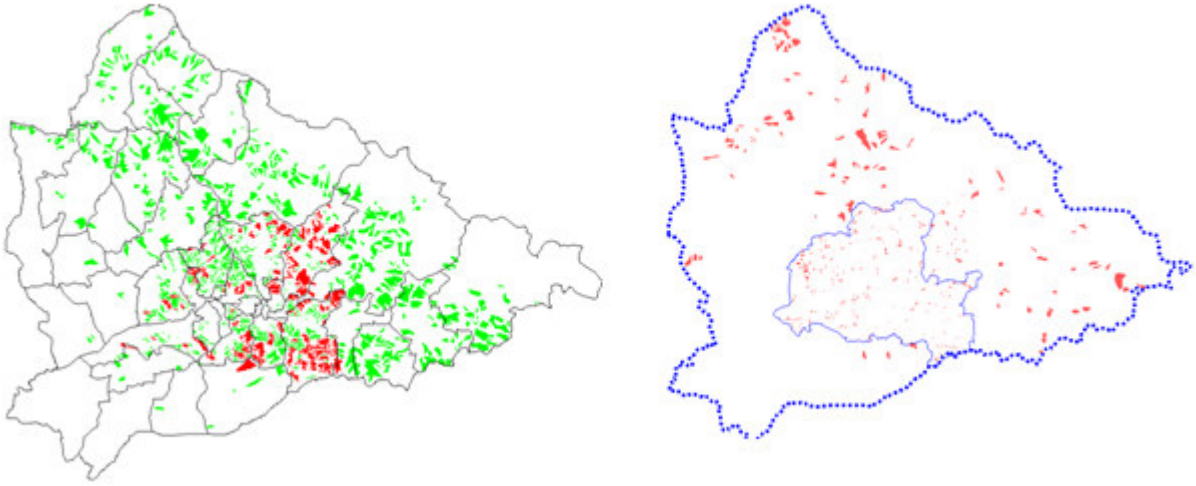

Fig. 9: Left: active (red color) and passive (green color) land slide areas; Right: potential (red color) land slide areas with administrative boundaries of Tuzla municipality

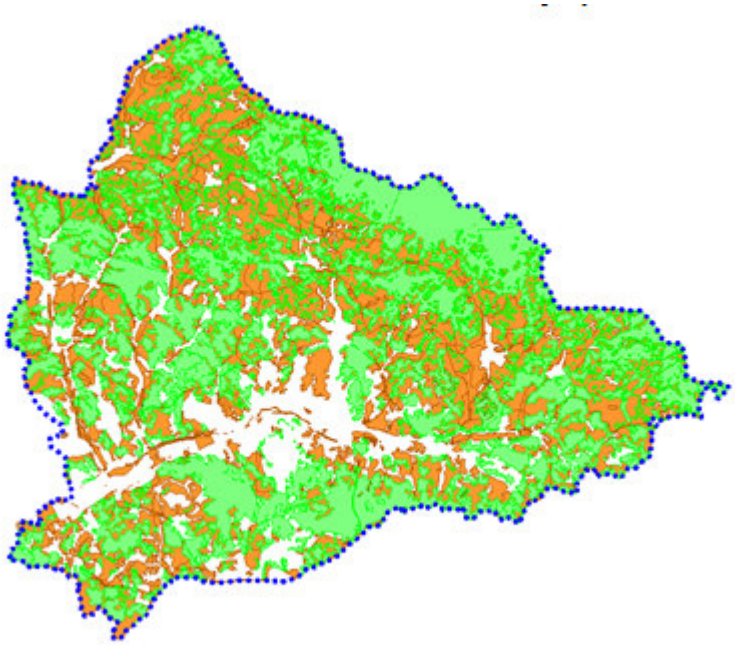

Fig. 10: Farmland (brown color) and forest areas (green color) with Tuzla municipality boundaries

By this way land use map of multi-criteria classification for buildings construction in Tuzla municipality is generated in GIS (Fig. 8).

3.8 Area balances

Table 5 shows area balances (in %) of land use classification. Area balances are commonly used as numerical quantifiers for comparative analysis of specific areas. Table 5 descriptions area distribution by individual classes (I to IV), and the impact of certain restrictions on the availability of land for construction high-rise buildings.

	Land Classes/ Restriction	I Extraordinary suitable for building in %	II Very suitable for building in %	III Suitable for building in %	IV Unsuitable for building in %	Total in %
	Without restriction	1.76	5.25	44.61	48.38	100
With restriction applied	Excluded active land slides	1.75	4.82	43.87	49.57	100
	Excluded active and passive land slides	1.71	4.28	39.65	54.37	100
	Excluded active, passive an potential land slides	1.69	4.19	38.70	55.42	100
	Excluded all kinds of land slides, forest and agricultural land, transportation and water areas	0.93	1.32	4.72	93.04	100
	Area differences with and without restriction applied	- 0.83	- 3.93	- 39.89	44.66	0.00

Table 5: Area balances (with and without restrictions)

4 CONCLUSION

Despite the large number of approaches and methods of land use planning, as well as significant progress in terms of application of information technologies, many issues related to the theory and practice of land organization are still open. The need for new methods and tools in spatial planning becomes particularly pronounced because of the problems caused by the trends of the time in which we live. These trends are related to the increasing shortage of land resources, demographic growth of the population, digital and information revolution, the development of traffic and transport, the growth of cities, the impact of humans on the environment and other phenomena. In other words, this is a period of very rapid changes, requiring fast reactions and responses. Pressure on land is not only evident through the needs of existing purpose, but also through increasing the number of activities and functions related to its use. To respond all challenges, urban planners needs new methods and techniques for analyzing and finding acceptable solutions.

As land is still very limited resource, it is important to maximize its potential, and optimize its use. Due to the complex needs and a large number of criteria (environmental, economic, sociological and natural) multi-criteria planning and analysis supports decision-makers in the many social activities related to environment, especially in the area of spatial planning. The methodology presented in the study for multi-criteria land use classification in GIS for building high-rise buildings based on the use of geospatial analysis tools and multi-criteria decision making methods, is used to solve the problem of evaluation and classification of land for the construction of high-rise buildings in Tuzla urban area. The results of the analysis clearly indicates the potential and restriction of areas for construction this kind facilities.

1 ABSTRACT

Any modern city in all respects is a complex phenomenon incorporating manifold of entities like governments (city and districts levels), plants, railway stations, transportation systems and many others. However, there exists one entity that from physical and informatics points of view may serve as a universal basis for the above manifold, and this is a computer network of the city. Indeed, everybody while pursuing certain objective can have an access to some storage of information, or to another townsman, or to other entities. Network is also a universal system for communication and control systems; on the .other hand, the network by itself is only the set of performance capabilities and nothing beyond.

City Network (CN) can be represented as a complex hierarchical system of different nodes. At that, each node is understood as a simple network's node or a local network or a system of local networks, that joints some subset of users or end clients. The fact that the CN structures and functions represent a real city life is not fantastic any longer.

The above assumption evidently leads to a consequence that Network Centric City (NCC) idea should be selected as a new subject of research and investigation. Obviously, NCC is not a simple network. So, the main idea of such representation of the advanced urbanization is to perceive global ideas and processes (business processes) underlying the city control and government system, population distribution, quality of life control and assessment, medical systems, transportation systems, ecological conditions' assessment, disaster prevention, etc.

The paper intends to look at the urbanization problems from computer science point of view. Up to date city is presented in the light of the network centric idea. Computer network at a physical level includes different networks at least as follows: optical networks, different kind of wireless networks, cell networks, etc. Different important problems of urbanization could be solved provided that a topology of city networks, their functions, descriptions, location and other data are available. Moreover, NCC can be used for future planning and urban development.

2 INTRODUCTION

The idea of considering a modern city as an element of the advanced ICT is not a novelty. Many ideas in this area have been evolved and appeared in print since the 70-ties of last century, so, an extensive literature is currently available. This issue also is actively discussed at the CORP conferences, and in this regard the below references give an outlook of the papers published during five last years in the CORP Proceedings. At that, it is worth noting that investigation of the modern city as an "electronic city" was carried out from the standpoint of townmen and/or city architects investigating the urbanization problems. Thus, reference [1] introduced a concept of "Network City". Many habitual attributes of a conventional city are allegorically represented by their electronic analogues like, for instance, [1]:

"bookstores ←→bitstores,

stacks (in libraries) ←→ servers,

galleries ←→ virtual museums, etc."

And Internet is considered as the network basis.

The other publication [6] notes that «It is incorrect to believe that websites represent a cyber city or a virtual-city because they can only represent a part and never the whole city. These websites, holding information about cities, are popularly known as cybercities, cyber cities, digital cities, e-towns, e-cities, informational cities, intelligent cities, telecities, virtual cities, virtual environments, virtual worlds, etc.» The above is difficult to argue with. Naturally the modern city can hardly be represented exclusively through the internet.

The following important comment [10] concludes that «In today's global economy, competition does not occur between countries, but between cities». Indeed, the up to date competition level first and foremost exists between megapolises rather than between countries. This is why many megapolises turn into centers of economics that forms the megapolis appeal in other aspects as well, e.g., Hong Kong, Singapore, Shanghai, New-York.

The idea of representing the modern city as a certain virtual network looks rather productive. So, networks of various types are developing amazingly fast due to their unlimited capacities to provide for a fast and efficient access to heterogeneous information and for various systems management. Here the wireless communications component of the virtual network takes on special significance. It is noted in [10] that «Some of the reasons cities cite for setting up their wireless infrastructure include:

- • Economic development
- • Social betterment
- • Government efficiency
- • Tourism and Marketing»

Thereby, the importance and promise of the wireless networks is accentuated.

Currently one might say that the network centric architecture of the modern city should be singled out for further discussion as an independent subject of inquiry. Notion of "Cyber citizen" (CbCz) is the most important component in the network centric concept. Modern megapolis does not exist without a man, thus, the NCC idea cannot be correct. CbCz is the main consumer of information, main source of information and plays a key role in NCC.

First and foremost NCC is aimed at providing for individual rights, political and religious liberties, ecological safety, for individual needs satisfaction and accounting for his/her opinion regarding the complete scope of the modern megapolis problems like ist vital activities and development; protection agaionstt terrorism, gangsterism and other infrigements of public and individual life. Economics, finance and manufacturing determine a potential of the modern city and form the basis for developing its other constituents including CbCz.

An extremely fast running of all processes, especially, in decision-making both at individual and governmental levels is the principle issue in NCC. At that, so called nonmaterial assets – information and knowledge- take on special value.

NCC is defined by forming a new sector in the megapolis vital activities that is informationware being realized through the megapolis information system (NCIS).

NCIS penetrates into all spheres of the moderm megapolis vital activities from individual to public and from informational to manufacturing.. Основной продукт NCIS major product are data, information and knowledge.

Information security along with megapolis protection against potential threats including the tightly bound informational and physical ones.

Finally, NCIS evolves two important constituents of an individual: consience and every day life. The individual evolution inevitably affects the modern megapolis as the habitat of other cathegory that is the megapolis modern information community.

Thus, under the angle of NCC idea the modern megapolis can be represented by three constituents: decision-making system and city management (NCDMS); system realizing the passed laws and managerial decisions (NCDRS), and system for information-ware of the two above systems (NCIS). Major objective of NCC idea is to assure high level of comfort for individuals living in the city or visiting it on business, for rest, tourism, etc.

3 NC INFORMATION SYSTEM

Generally speaking, the city information system could be considered as a certain system of elements: development or delivery of information resources (computers, software, telecommunications facilities, office equipment, non-electronic information resources, etc.); generation of data; information and knowledge

(science, education, ideology, politics, mass media, scientific and technical information services, observation and monitoring systems, internet); information services (education, libraries, museums, post, communications, financial activity, governmental activity, legal services). It is clear, that the collection of the above constituents will be somewhat different for each megapolis. However, the given collection is rather some system aimed at solving definite problems and meeting definite needs of the modern megapolis than just a collection. The following definition for the megapolis network centric information system is proposed in the above regard.

NCIS – is a system and a complex of interrelated organizational and technical measures intended for the acquisition, collection, transmission, processing, storing, layout, and representation of information, software, computer communications and equipment to be used at supporting decisions made in favour of the citizens, business and the city managerial bodies.

It would be quite appropriate to single out five relatively independent subsystems in NCIS:

- 1.information acquistion subsystem (sensors' system);
- 2.subsystem of information collection, processing, representation, storing, and output (data processing centers, information and knowledge storages, web sites, and other sources);
- 3.computer communications subsystem:
    - data transfer channels from the sensors' system (USB, KB, space, radio relay links, cell and satellite communications, telefone and fiber-optic lines, television and digital Telefone channels);
    - computer networks (local computer networks, Intranet, Internet).
- 4.software and computer hardware subsystem;
- 5.security and information protection subsystem.

Because of certain limits this paper will only discuss some of the above subsystems in detail.

3.1 Network subsystem (не вижу в предшествующей части)

Network subsystem is a global virtual network that uses all possible physical channels for information exchange, thus, covering the modern megapolis.

Note, that the modern megapolis represents "a state in miniature" and reflects the modern society structure. Aggregate of peoples' cumulative activity. Economics, politics, culture, education, science, security, medical care, ecology, etc. Information generation and consumption are the most important activities. Information is recognized as the most important resource, and new information technologies become basic technologies forming other activities based upon complex network architecture.

Modern city could be represented as some system that is penetrated by another important system – system of networks for exchange of data, information and knowledge. This is, in fact, a system of computer networks that supports solving problems of data exchange between all kinds of computer systems and citizens. Computer networks also provide for the city communications with the "outside world" within the same state as well as within the "world web". Computer network forms a basis for creating other advanced networks like television systems, cellular communications, various scales observation and monitoring systems, space systems and many others.

At that, up to now the physical networks used to develop spontaneously and to complpetely neglect any intercoordination and planning as needed for the city unified integrated network.. Moreover, a considerable set of physical networks is autonomous and not ideologically interrelated. The above is caused by many reasons including the fact that many physical and logical networks are commercial and, thus, compete with each other. Nevertheless, from the point of view of the unified city structure this situation cannot be acceptable since it generates many new problems and does not solve the old-established ones. Problems of ecology, electromagnetic compatibility, individual rights and other could be attributed as new problems. The problems of fighting against gangsterism, terrorism, street criminality, narcotism belong to the cluster of old-established problems.

Also a strong duplication of networks exists in some places, and their complete absence in other like the megapolis outskirts. In a consequance the megapolis faces an irrational use of active space, energy overrun,

noises generation, as well as other negative factors.Table 1 gives a retrospective of dynamics in growth of various St. Peterburg networks during several past years.

So, an effective planning and developing the computer networks system is the first priority task for the modern megapolis that requires a complex approch to its solving. At that an engagement of versatileprofessionals is a must as well as specifying the specialized research programs at the city governmental level.

#	Cathegories of computer (physical) networks run in St. Petersburg	2000	2003	2006	2009
1.	Networks, distributed computer systems under federal jurisdiction, Ministries and authorities.	5	6	12	16
2.	Networks, distributed computer systems under St. Petersburg Government, regional and municipal jurisdictions	3	8	21	24
3.	Commercial networks	11	26	58	76
4.	Specialized networks and distributed information systems (Universities' networks, networks of R&D institution, etc.)	5	12	18	22

Table 1.

3.2 Sensors' subsystem (в предшествующей части: sensors' system)

Under a certain angle of consideration the modern city could be represented as a systems of heterogeneous nature and purpose sensors..In this case the situation is pretty much similar to the network system situation.There exists a great number of various sensors that are not interrelated within a unified system due to the same reasons as in case of the network system (Fig. 1)

In the precence of advanced sensors' system many problems would be solvable at an absolutely new level. The tasks like ecological monitoring, weather status, situation in the streets and city districts on the whole, transportation system status and traffic flows as well as many other would be resolved at an absolutely new qualittaive level.

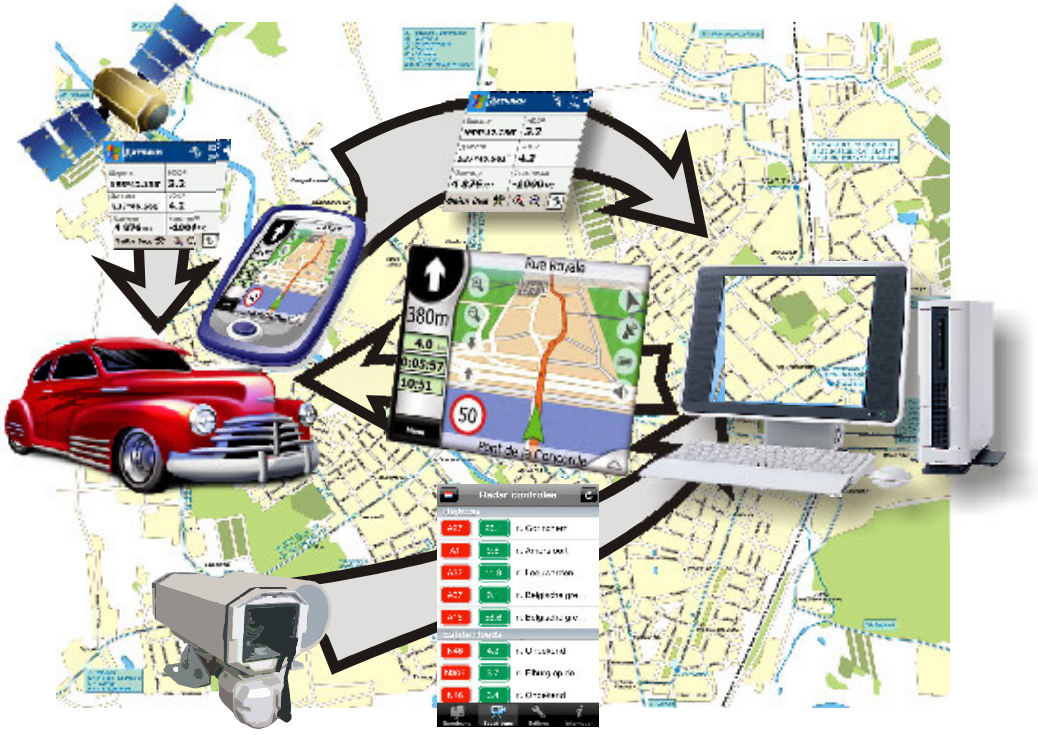

Fig.1 representation of th emodern city as a sensors' system

It is expected that in the nearest future human beings living or located within a city boundary will play a role of the main sensors. The human beings can and must be the main information sources regardring the environment as well the observation objects, at that, his/her level of health and psycho-emotional condition should be observed (Fig. 2).

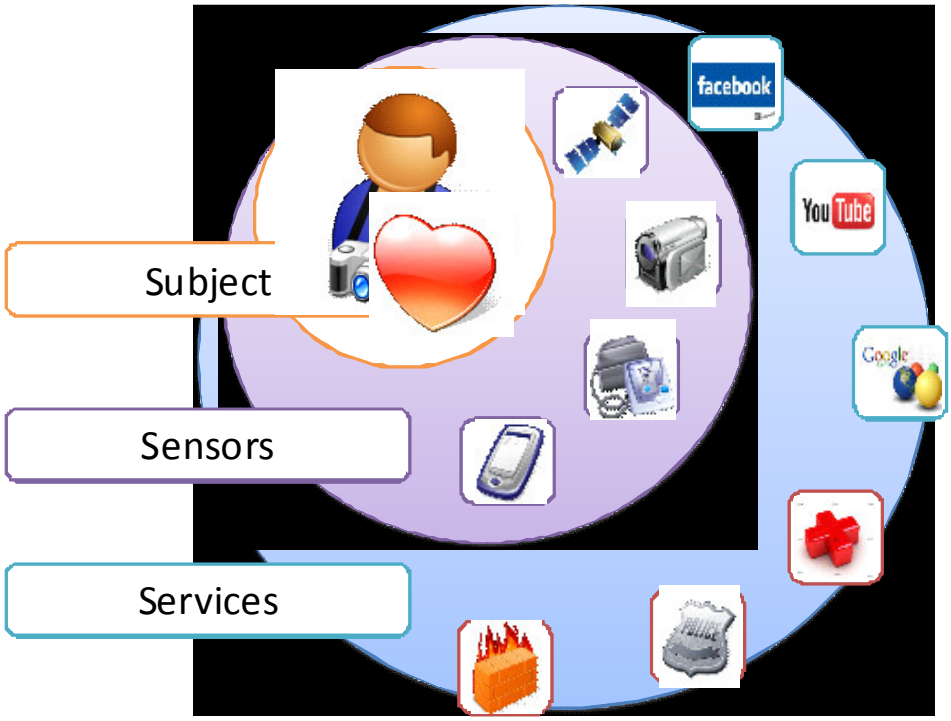

Fig.2 Human being – sensor and observation object in the modern city

For instance, in presence of proper sensors and matching monitoring system the preventive health care as well as acute care and medical treatment for the megapolis residents can acquire an effectively new level.

3.3 Selfsynchronization ???

Considering the fact that the modern megapolis is a strongly stratified envirinment any subsystem, city element (starting with its resident) from the computer point of view should possess an important property of self-synchronization. Here self-synchronization is understood as a capacity to enter the global network and to interract with its other members. It seems impossible in the present day reality to build a city where each resident, each social or other organization would be assigned strict regulations in behaviour and activities. This is why the property of self-synchronization supports a possibily of decentralized existence and management for all entities of computer network from the abstract to physical ones.

Thus, the information system (IS) builds a foundation for the modern megapolis, and all its activities and development are based on this foundation. Advanced IS lays the basis for a comfortable living and functioning of .CbCz, that is a computer mapping of a human resident..

4 NC DECISION MAKING SYSTEM

View on the modern city as on the sensors' system and global computer network puts in the forefront absolutely new requirements to the conventional city management problems and tasks as well as to the city development, reactions to man-caused and natural cataclysms.Presence of the distributed and advanced computer network and sensors' system gives unique opportunities in regard to a whole set of problems faced by the modern city as well as comprehensive facilities for optimizing all expenditures aimed at upkeeping the high habitational comfort.

On the other hand the above presence of advanced computer network and sensors' system generates a number of problems related to huge data flow and a need of making decisions in real time. The more data exist the more reliable is the knowledge of a real situation, on the other hand huge data flow generates a problem of data processing and interpretation. In the long run an uncontrolled data level brings the

investigated situation near the situation specified by the problems caused by data deficit. So, in the above case triggers the dialectic law: “everything and nothing are two extremities that converge”.

To solve the above problem a concept of data harmonization, integration and fusion could be used [16], that would allow for organizing a decision-making system at different hierarchical levels.. The concept of developing large-scale corporate systems and large-scale monitoring systems could be adopted by the given idea.

In addition to the substantiated development of different hierarchical levels the problem of making decisions at the given hierarchical levels takes on a special significance. Under the angle of the city management the considered hierarchical levels could be: house (community), residential area, district, city. The hierarchical levels could be easily singled out in a number of city services like police, health care, emergencies control, and other traditional city services. A near-term outlook would likely take a city resident and his/her “Cyber citizen” (CbCz) as an entry hierarchical level for the most city systems and services.

Problem of making decisions in the modern city is a nontrivial task as respects a definite individual [3] or various city services and systems. Accountibg for conventional mathematical methods of decision-making one cannot but admit that they have a limited range of applicability as well as a limited possibility of their use. In this regard lately the interest is attracted by the systems of artificial intellectuality that easily incorporte mathematical and simulation models and also allow using heuristics and expert knowledge, thus, targeting at a new quality in application of decision-making support systems. First and foremost, they exhibit high flexibility and customizability, almost unlimited capacity to be modifidied and evolved, as well as to be connected up with a wide range of models’ classes. At that, such systems can and must be available for an average resident being in possession of a regular mobile- or smart-phone.

5 NC DECISION REALIZATION SYSTEM

In a computer era the made decisions’ realization system functions in a highly variable situation. At that, depending on the made decision level, for instance, strategical, operational, tactical the time of decision obsolescence will significantly differ depending on the level. Note, that .costs of error will also be rapidly changing depending on the level, however, in a reverse order than the obsolescence time.

Control automation problems in organizational and technical systems, and modern megapolis could be considered among such systems, had been studied over 40 years ago, at the beginning of the seventies of the last century. The given idea was well formulated by D. A. Pospelov [17] and is known since as “situational control”. The above mention approach had specifically emphasized the fact that well developed mathematical apparatus and automatic control theory techniques are not applicable to for the case of organizational and technical systems. The ideas proposed by D. A. Pospelov were somewhat extended by the concept of “network centric war” formed in the USA at the end of the twentieth century and in the beginning of the twenty first [18].

The existing body of network centric ideas allow for forming an integral concept that regards the made decisions’ realization process at various levels in control and management hierarchy, particularly, at the level of the modern megapolis resident as the very essence of the modern megapolis.

In the nearest future the main features of the decisions’ realization in NCC will be as follows:

- high rate of decision-making as well as high rate of its realization;
- high degree of decentralization in decision-realization, and consequently, high level of self-dependence in decision-making at various hierarchical levels;
- adaptability of the made decisions under rapidly changing situation’s conditions;
- reasoning ability at the “situation” level rather than at “data and facts” level;
- common introduction of the artificial intellectuality means and techniques destined to avoid critical errors and obvious misoperations under rapidly changing situation’s conditions and source data deficiency. Potential advantages as stipulated by NCC concept realization cannot be implemented automatically, so, consolidation of the skilled professionals from many subject areas .as well as engagement of citizens and governments will be required.

6 CONCLUSION

Modern city is a global information system where the modern citizen plays a key role as a user and as an active participant. NCC concept assumes considering the urbanization problem from computer point of view, at that, not neglecting conventional approaches.

Under the ICT rapid development the role of computer sciences and professionals is expected to continuously grow. At that, ICT will be rapidly introduced to all spheres somehow related to the modern individual activities.

At arranging for planning and development of the projects for the new city's districts or remodeling the old ones it seems reasonable enough to invite professionals developing global computer networks and large-scale information systems. Modern society cannot advance without paying a close attention to developing in all spheres of modern megapolis life the information networks and decision-making support facilities and systems.

It looks like that the NCC concept would inspire the development and practical realization of modern megapolises structuring and development tasks.

It might be quite reasonable to represent the CNN concept by three basic subsystems.

Decision-making system and management (NCDMS). Legislative and executive authorities are ascribed to this system.

System realizing the passed laws and managerial decisions (NCDRS). Here the immediate performers who realize the made decisions and acts of law in practice are meant; first of all they include police, emergency services, medical care, economic subsystem, etc.

System of the two first systems information support (NCIS).

"Neue Kollektive" – eine zentrale Herausforderungen für die zukunftsfähige Stadtplanung

Tatjana Fischer

(Univeristät für Bodenkultur Wien, Department für Raum, Landschaft und Infrastruktur, Institut für Raumplanung und Ländliche Neuordnung, Peter Jordan-Straße 82 A-1190 Wien, tatjana.fischer@boku.ac.at)

1 ABSTRACT

Im Jahr 2008 wurde ein vom Ökosozialen Forum Wien beauftragtes Projekt abgeschlossen, dessen Ziel es war, sich der großen Herausforderung „Alterung der Bevölkerung" interdisziplinär anzunehmen und gleichsam „mit den Augen eines jungen Forscher-/-innen-Teams" die Versorgungssituation älterer Menschen in der Stadt Wien „unter die Lupe" zu nehmen. Dem Leitbild einer „Stadt der kurzen Wege" folgend, bestand das Ziel der Forschungsarbeit darin, stadträumliche Spezifika zu verstehen und raumdifferenzierte Grundsätze zu erarbeiten, damit Wien auch in Zeiten demographischer Dynamik hinsichtlich der Versorgung seiner – nicht nur älteren – Bewohner/-innen „fit für übermorgen" bleibt.

Die empirische Forschung brachte hervor, dass sich die sog. älteren Menschen – statistisch gesehen beginnend mit dem 60. bzw. 65. Lebensjahr – längst nicht mehr in ein uniformes Schema hinsichtlich ihrer Charakteristika einfügen lassen. Zweifelsfrei können dieser Anspruchsgruppe eine Reihe an Gemeinsamkeiten zugesprochen werden, dennoch sind es die großen Heterogenitäten hinsichtlich deren Lebenslage – definiert als ein Bündel sozioökonomischer, demographischer sowie statistisch nicht messbarer Determinanten – die zu Herausforderungen in der (infrastruktureller) Angebotsplanung seitens der Stadtpolitik und -verwaltung führen.

Inwiefern – aufbauend auf den Ergebnissen der oben genannten Studie – eine zukunftsfähige Stadtplanung von „neuen Kollektiven" hinsichtlich deren Ansprüchen

an eine lebenswerte Stadt bei der Angebotsplanung auszugehen haben wird, möchte dieser Beitrag beleuchten.

Thematische Schwerpunkte dabei bilden die beiden Bereiche Versorgung mit Gütern und Diensten des täglichen Bedarfs sowie Erholung und Freizeitgestaltung.

2 FORSCHUNGSDESIGN DER STUDIE

Das Hauptanliegen der Forschungsarbeit „Stadt der kurzen Wege aus ökosozialer Sicht – Nahversorgung und Naherholung in Wien vor dem Hintergrund der Alterung" bestand im Aufzeigen und Verstehen der Zusammenhänge und Wechselwirkungen zwischen demographischem Wandel, Raumstrukturen und dem räumlichen Verhalten. Das Herausgreifen der Thematiken „Altsein und Älterwerden in Wien" diente dazu, zu zeigen, inwiefern räumliche Gegebenheiten für die Organisation und Bewältigung des Alltags älterer Menschen relevant sind und – im Allgemeinen – die Befriedigung der Bedürfnisse älterer Menschen beeinflussen. Daran anknüpfend war es Aufgabe auszuloten, welche Aspekte die Stadtplanung in den raumrelevanten Handlungsfeldern „Nahversorgung" und „Naherholung" im Hinblick auf die Personengruppe „60+" mitzubedenken hat.

Um die Komplexität des Themas zu veranschaulichen, wurde als Indikatorengruppe zur Bewertung der städtischen Versorgungsqualität die Personengruppe „60+" ausgewählt. Dies deshalb, weil sie die am stärksten wachsende Altersgruppe überhaupt darstellt und sich durch eine große Heterogenität hinsichtlich der Lebenslagen und den damit verbundenen Ansprüchen an den Stadtraum auszeichnet, die das Nutzungsmuster infrastruktureller Einrichtungen prägen. Aufgrund der gravierenden Unterschiede in der subjektiven Raumtüchtigkeit ist eine hohe Sensibilität innerhalb dieser Bevölkerungsgruppe gegenüber räumlichen Barrieren und Versorgungsdefiziten zu erwarten.

Innerhalb dieser Personengruppe erfolgte eine Fokussierung auf die rüstigen und mobilen älteren Menschen, weil sie aufgrund der (eigenen) Raumtüchtigkeit ihre Versorgung (noch) selbst übernehmen (können) und ihnen somit räumliche Aspekte im Alltag regelmäßig begegnen. Auf zuhause betreute immobile ältere Menschen wurde ergänzend eingegangen, sofern raumrelevante Aspekte für die an ihrer Betreuung Beteiligten (Angehörige, professionelles Personal verschiedener Trägerorganisationen) unmittelbar von Bedeutung sind.

Der Erforschung der Lebenssituation älterer Menschen mit Migrationshintergrund kam kein inhaltlicher Schwerpunkt zu. Erkenntnisse diese Bevölkerungsgruppe betreffend wurden – sofern sie im Laufe der Forschungsarbeiten gewonnen werden konnten – eingefügt.

Die Darstellung der Lebenssituation älterer Menschen konzentriert sich thematisch hinsichtlich der Nahversorgung auf die Versorgung mit Gütern und Diensten des täglichen Bedarfs sowie die (sozial-)medizinische Versorgung mit ambulanten Diensten und stationären Einrichtungen und hinsichtlich der Naherholung auf Außer-Haus-Aktivitäten in der Freizeit im Umfeld der Wohnung oder des Wohnorts an sogenannten „Orten im Freien".

Der räumliche Bezugsrahmen für die Untersuchung ist Wien. Da allerdings auf kleinräumiger Betrachtungsebene große Unterschiede hinsichtlich der soziodemographischen Struktur, dem infrastrukturellen Versorgungsniveau und der Stadtgestalt bestehen und auf diese raumspezifischen Differenzen innerhalb der Stadt hingewiesen werden muss, wurden drei verschieden ausgeprägte Stadträume als „reale" Belege (Beispiele) für die Untersuchung ausgewählt:

Das Beispiel „Wilhelminenberg" als ein Wohngebiet in Stadtrandlage und Wienerwaldnähe im 16. Wiener Gemeindebezirk, das durch Alterung der Bevölkerung gekennzeichnet ist.

Das Beispiel „Neubau" – ein Mischnutzungsgebiet in dicht bebauter Innenstadtlage im 7. Wiener Gemeindebezirk, das sich durch große Vielfalt an Nahversorgungseinrichtungen auszeichnet.

Das Beispiel „Hirschstetten" als ein Stadterweiterungsgebiet in Stadtrandlage nordöstlich der Donau im 22. Wiener Gemeindebezirk, das sehr gut mit (privaten und öffentlichen) Grünflächen ausgestattet ist.

Die Vielschichtigkeit und Komplexität des Projekts offenbarte sich bei der Suche nach geeigneten Methoden zur Operationalisierung der Fragestellung und der Festlegung und Chronologie der Arbeitsschritte.

Deshalb näherte sich das Forscher-/-innen-Team dem Thema durch die Formulierung von Vermutungen über Wechselbeziehungen zwischen demographischem Wandel – im Speziellen der Alterung der Bevölkerung – und stadtraumrelevanten Aspekten betreffend die Nahversorgung und Naherholung älterer Menschen an, die in weiterer Folge die Forschungsmethodik leiteten und letztlich mit den gewonnenen Erkenntnissen – Informationen von Älteren und Experten/-innen einerseits, Synthese der Ergebnisse durch die Forscher/-innen selbst andererseits – verglichen werden konnten.

Den Bearbeitern war die Notwendigkeit der Verschränkung von raum- und sozialwissenschaftlichen Aspekten bewusst. Weiters wollte man der inhaltlichen Komplexität durch Zerlegung der Forschungsfrage in Teilfragen begegnen und diesen dann wiederum spezifische Methodensets zuordnen. Neben quantitativen und qualitativen Methoden der empirischen Sozialforschung wie Befragung der älteren Menschen (und von Fachleuten) sowie Beobachtung von „Bewegungen im Raum" kam der Ortsbegehung, d. h. dem unmittelbaren Erleben „räumlicher Bedingungen und Umstände" durch die Bearbeitenden große Bedeutung zu. Die gesamte Erhebungsphase folgte dem Grundsatz des „so nah wie möglich am Menschen Seins" und des „problemzentrierten Arbeitens". Ergänzt wurden die so gewonnenen Erkenntnisse durch die Inhalte der bereits zu diesem Zeitpunkt vorhandenen Fachliteratur aus den Themenbereichen Raum- und Landschaftsplanung, Soziologie und Ökonomie.

Es wurden 19 Expertengespräche geführt, wobei die Gesprächspersonen aus folgenden Fachbereichen stammen:

- Mobile Dienste und teilstationäre sowie stationäre Betreuung älterer Menschen
- Soziologie
- Stadt- und Landschaftsplanung
- Integration älterer Menschen mit Migrationshintergrund
- Seniorenpolitik

Ältere Menschen um Alter von ab 60 Jahren wurden in den drei Untersuchungsgebieten in Form von Kurzinterviews spontan an ausgewählten Orten der Nahversorgung (347 Personen) und Naherholung (614 Personen) befragt.

Weiters gelang es, über Institutionen bzw. Einrichtungen und organisierte Treffpunkte älterer Menschen kooperative Ansprechpersonen in dieser Bevölkerungsgruppe zu gewinnen. Es wurden 67

Leitfadeninterviews geführt, in denen 72 Personen (Ehepaare wurden gemeinsam befragt) zu Wort kamen. Unter den 72 Befragten befinden sich zehn ältere Menschen mit Migrationshintergrund.

3 DIE ÄLTERE WIENER STADTBEVÖLKERUNG

3.1 Zentrale Bedürfnisse – der kleinste gemeinsame Nenner der Älteren

So vielfältig wie die älteren Menschen selbst sind auch deren Bedürfnisse. Viele der in den Gesprächen geäußerten Alltagsprobleme bezogen sich auf Versorgungsfragen, wobei zu beachten ist, dass jeweils die eigene Lebenssituation den Hintergrund der Ausführungen bildet und diese somit immer Schilderungen der subjektiven (Raum-)Wahrnehmung und des subjektiven Erlebens des Altseins in der Stadt sind.

Es darf angenommen werden, dass die hinter den Aussagen stehenden Bedürfnisse mit den Bedürfnissen von Personen in ähnlicher Lebenslage korrespondieren, besonders dann, wenn eine unzureichende Befriedigung der Grundbedürfnisse zu einer erheblichen Beeinträchtigung des Wohlbefindens oder der Gesundheit führt.

Zudem lassen sich Verschiebungen bezüglich der Prioritäten innerhalb des Bedürfnisspektrums im Zuge des Älterwerdens erkennen: Im Zuge des Älterwerdens kommt den Bedürfnissen nach Autonomie, Identität bzw. Identifikation mit der Wohnumgebung, Sicherheit, Zugehörigkeit und Partizipation große Bedeutung zu.

Das Bedürfnis nach Autonomie spiegelt sich in den Äußerungen der Älteren insofern wider, als der Wunsch nach Selbstständigkeit, Unabhängigkeit und Selbstbestimmung immer durch das Anliegen nach einem eigenständigen Leben so lange wie möglich zuhause zum Ausdruck gebracht wird. Eng damit verbunden ist der Wunsch, (auto-)mobil zu sein und zu bleiben, um auch weiterhin den Alltag unabhängig und flexibel gestalten zu können. Der (eigene) PKW stellt demnach einen wesentlichen Faktor der subjektiven Lebensqualität dar, vor allem für Menschen in jenen Stadtgebieten, wo die Versorgung mit Öffentlichen Verkehrsmitteln den Ansprüchen der Befragten nicht genügt.

An dieser Stelle ist anzumerken, dass die Möglichkeiten, die die Stadt älteren Menschen bietet, und die Herausforderungen, die sie im Gegenzug an sie stellt, von befragten Experten/-innen teilweise umfassender gesehen werden und Widersprüchlichkeiten zu den Anliegen Älterer zu erkennen sind.

So interpretieren die Expertinnen und Experten den Wunsch nach Selbstständigkeit, Unabhängigkeit und Selbstbestimmung als Herausforderung für die (zukünftige) Planung (sozial-)medizinischer Dienste, da seitens der Älteren professionelle Hilfe im mobilen und semistationären Bereich einerseits in sehr unterschiedlichem Maße tatsächlich in Anspruch genommen wird und mobile Dienste meist erst dann gerufen werden, wenn eine selbstständige Lebensführung wirklich nicht mehr möglich ist. Zudem besteht aus Sicht der Experten vielfach große Angst vor stationären Betreuungseinrichtungen, da sie aus Sicht der älteren Menschen mit der Forderung nach Selbstbestimmung unvereinbar sind.

3.2 Worin sich ältere Menschen ähneln

Aus dem Stellenwert der eben genannten Bedürfnisse im Leben älterer Menschen lassen sich demnach eine Reihe von Gemeinsamkeiten dieser – wie in weiterer Folge gezeigt werden wird – sehr heterogenen Altersgruppe erkennen. Homogenität der älteren Menschen besteht hinsichtlich der Bedeutung der Wahrung der Privatsphäre sowie des Versuchs des Erhalts gewachsener sozialer Beziehungen. Dazu zählen auch Ähnlichkeiten bezüglich der Wohnungswahl, der Wohnzufriedenheit und der Sesshaftigkeit sowie der Raumwahrnehmung und Sensibilität bezogen auf die Wahrnehmung räumlicher Veränderungen im Wohnumfeld. Bemerkenswert ist, dass (infrastrukturelle) Ausstattungsdefizite der Wohnumgebung von den älteren Menschen durch andere Faktoren vielfach kompensiert werden und deshalb dem positiven Raumempfinden nicht entgegenstehen. Auffallend ist weiters die Ansicht vieler Befragten, sich im Falle der eigenen Fahruntüchtigkeit in fußläufiger Erreichbarkeit vom Wohnstandort versorgen zu können, obwohl die Möglichkeiten dazu vor allem am Stadtrand meistens nicht gegeben sind. Dazu kommt, dass die Bereitschaft zu einem Wohnstandortwechsel seitens der Befragten sehr gering ist. Veränderungen im unmittelbaren Wohnumfeld wie etwa der deutliche Anstieg der Wohnbevölkerung (einschließlich des vermehrten Zuzugs von Menschen anderer Ethnien), bauliche Veränderungen sowie Veränderungen hinsichtlich der infrastrukturellen Ausstattung werden genau beobachtet. Positive Veränderungen werden wohlwollend zur Kenntnis genommen und negative Veränderungen leiten das wehmütige Zurückdenken an vergangene Tage ein.

Hinsichtlich der Versorgung schätzen die Älteren die Gewährleistung von Wahlfreiheit in Bezug auf Güter und Dienste des täglichen Bedarfs – so halten viele als „Schnäppchenjäger" gezielt Ausschau nach für sie passenden Angeboten – sowie (sozial-)medizinische Betreuung. Letzteres zeigt sich daran, dass pflegende Angehörige und die zu betreuende Person Wert darauf legen, die Trägerorganisation mobiler Dienste selbst auswählen zu können.

Älteren Menschen mit Migrationshintergrund sind tendenziell ein schlechterer Gesundheitszustand und das frühzeitige Einsetzen des Alterungsprozesses im Vergleich zu älteren Menschen ohne Migrationshintergrund gemein.

3.3 Indizien für die zunehmende Heterogenität der 60+

Aus der Befragung geht ein großer Facettenreichtum der untersuchten Bevölkerungsgruppe hervor, der sich primär aus der jeweiligen Lebenslage bestimmt. So spannt sich das Profil Älterer von den (genügsamen) Hochaltrigen, über die Hilfs- und Pflegebedürftigen und deren pflegenden Angehörigen bis hin zu den (finanziell) Unabhängigen, Flexiblen, (Auto-)Mobilen und schließt auch die immer größer werdende Anzahl an heute jungen rüstigen Seniorinnen und Senioren, „die das Leben zwischen 50 und 75 besonders genießen möchten" mit ein.

Dass subjektive Raumwahrnehmung und tatsächliches Raumverhalten nicht nur durch objektive (infra-)strukturelle Raumausstattungsqualitäten bedingt sind, sondern die Verzerrung der Wahrnehmung und Definition der eigenen Aktionsräume sehr stark von der subjektiven Raumtüchtigkeit abhängen, zeigt die folgende Abbildung. Sie zeigt das Ergebnis der Befragung rüstiger, (auto-)mobiler Senioren hinsichtlich der Frage, was sie unter Naherholung verstehen.

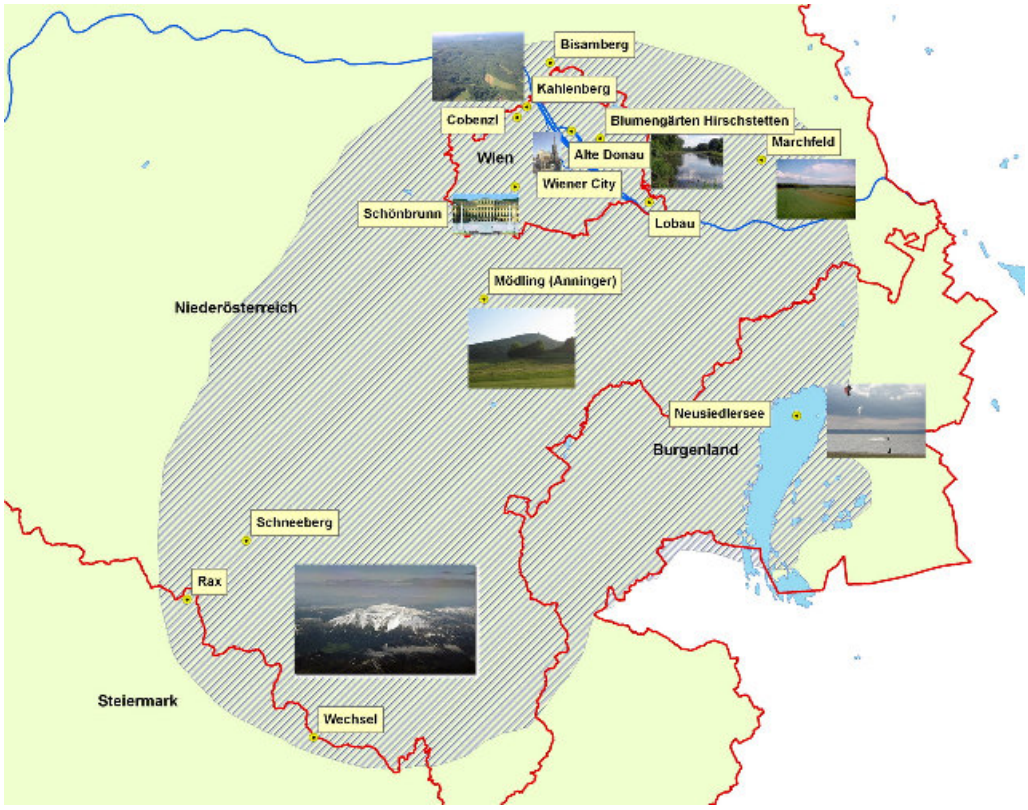

Abb. 1: "Naherholung"- eine Interpretation aus Sicht rüstiger, (auto-)mobiler Senioren

Die Heterogenität der Lebenslage gekoppelt mit gravierenden Unterschieden in den jeweiligen Bedürfnissen und dem Geltendmachen von Ansprüchen – die Gruppe der jüngeren Senioren/-innen zeichnet sich dabei durch „neuen" Mut und „neues" Selbstbewusstsein hinsichtlich der Artikulation von Wünschen aus – stellt die Stadt vor große Herausforderungen in der Angebotsplanung. Zu diesen zählen auch die sehr unterschiedlich ausgeprägte Bereitschaft der Älteren, sich mit dem „Altern und Älterwerden" rechtzeitig auseinanderzusetzen und im Bedarfsfall (organisierter externer) Hilfe tatsächlich in Anspruch zu nehmen.

Die Struktur und Organisation des Alltags variieren ebenfalls sehr, nicht zuletzt bedingt durch die sehr unterschiedliche Raumtüchtigkeit – ausgedrückt durch verschieden große Aktionsradien und damit

Erreichbarkeiten – der älteren Akteuren, den Zugang zu und Umgang mit Informationen sowie zur Erleichterung des Alltags die Nutzung neuer Technologien – um durch sie eventuell die Anzahl der zur Versorgung mit Gütern und Diensten des täglichen Bedarfs erforderlichen Außerhausaktivitäten zu reduzieren.

4 CHARAKTERISTIKA DER NAHVERSORGUNG UND NAHERHOLUNG ÄLTERER MENSCHEN IN WIEN

Das sich durch viele Gemeinsamkeiten und Unterschiede auszeichnende Profil der heute älteren Stadtbevölkerung formt auch die Ansprüche der Älteren an ihre Nahversorgung und Naherholung entscheidend mit. Dennoch lassen sich für beide Themenfelder aus der Befragung der älteren Menschen einige Kernaussagen ableiten:

So zeigt sich in Bezug auf die Nahversorgung mit Gütern und Diensten des täglichen Bedarfs, dass Einkaufen auch als Beschäftigung gesehen wird und deshalb für viele ein wesentlicher Grund ist, das Haus zu verlassen. Dazu gesellt sich eine sehr klare Zweigliedrigkeit des Einkaufsverhalten bei Lebensmitteln: zum Einen sind die kleinen, alltäglichen Besorgungen, zum Anderen die in größeren Zeitabständen stattfindenden Großeinkäufe (unter Nutzung des (eigenen) Autos) zu nennen. Parallel dazu wird das Vorhandensein von Fachgeschäften aus den Bereichen Fleisch, Obst und Gemüse sowie Backwaren sehr geschätzt. Die Befragten sind vielfach auch bereit, für bessere Qualität und besseren Service höhere Preise zu bezahlen. Allerdings wird die persönliche Ansprache beim Einkaufen seitens der Älteren nicht immer als wünschenswert empfunden, sodass die Anonymität der Supermärkte auch von Älteren durchaus geschätzt wird.

Dennoch wird die Monotonie großer Geschäftsstraßen vielfach als für das Einkaufserlebnis störend empfunden, da die Filialen großer Handelsketten das Angebot und Bild prägen.

Das Fehlen (geeigneter) Einkaufsmöglichkeiten sowie die körperliche Befindlichkeit der Älteren erfordern bei der Erledigung ihrer täglichen Wege die Hilfe Dritter. Dies sind meist die eigenen Kinder bzw. Schwiegerkinder. Diese Personen des Vertrauens begleiten die Älteren zudem, wenn Tätigkeiten zu erledigen sind, die vermehrte Aufmerksamkeit erfordern wie etwa Bankwege.

In Hinblick auf die medizinische Basisversorgung (Allgemeinmedizin, Apotheken) zeigen sich die befragten Personen zufrieden. Ein Manko stellt die Versorgung mit Fachärzten dar, da die Wahl vielfach nicht in Abhängigkeit vom eigenen Wohnstandort erfolgt, sondern vor allem vom (langjährigen) Vertrauen abhängt. Sofern institutionelle Angebote wie etwa Essen auf Rädern in Anspruch genommen werden, besteht der Wunsch nach möglichst großer Flexibilität.

Verflechtungen von Erledigungen des täglichen Bedarfs mit der Erholung dienenden Freizeitaktivitäten ergeben sich durch Wegeketten: Viele der Befragten genießen den Schaufensterbummel und das Flanieren, im Zuge dessen auch gerne Kleinigkeiten gekauft werden. Zwischendurch wird auch gerne das Kaffeehaus aufgesucht, auf einer Bank gerastet und das (innerstädtische) Treiben in den Straßen beobachtet.

Das Stadtzentrum spielt somit – gemeint ist hier im Konkreten die Wiener Innenstadt – eine wichtige Rolle in der Naherholung der Älteren. Ihre Atmosphäre und ihr Angebot lassen sich kaum kompensieren.

Hinsichtlich der Naherholung konnten aus der Befragung folgende Erkenntnisse gewonnen werden: Die Qualität des Naherholungsangebots im unmittelbaren Wohnumfeld wird – unabhängig davon, ob die Befragten es nutzen oder nicht – jedenfalls wahrgenommen. Vor allem im innerstädtischen Gebiet wird das Fehlen ausreichender Grünräume als Mangel empfunden und die Nutzbarkeit vorhandener Grünflächen in Frage gestellt. Der Nutzungsdruck auf die wenigen vorhandenen Möglichkeiten ist enorm. Neben dem eigenen Gesundheitszustand werden im innerstädtischen Gebiet häufig Konflikt- und Angstsituationen in den Park- und Gründflächen als Hemmnisse für die Nutzung und als wesentliche Einschränkung des eigenen Aktionsradius erlebt. Auch das zunehmende „Verbauen“ von Freiflächen wird bemängelt, ebenso deren schlechte Pflege bzw. durch fehlende Schneeräumung deren Nicht-Nutzbarkeit im Winter.

Für fast alle Befragten stellt neben dem Vorhandensein vor allem die (leichte) Erreichbarkeit vom eigenen Wohnstandort aus eine Bereicherung der Lebens- und Wohnqualität dar. Dies auch deshalb, weil Naherholungsgebiete vorwiegend als der Erholung dienenden Rückzugsräume gesehen werden und

sportliche Aktivitäten im Freien – mit Ausnahme des „mit dem Hund gehen" – sich an etwas weiter entfernten Zielen stattfinden.

Diese Tagesausflüge erfolgen zumeist in Begleitung der Familie oder Freunden bzw. werden auch von Vereinen wie etwa den Pensionistenklubs, den Naturfreunden und dem Alpenverein sowie den Pfarren organisiert. An den großen Wiener Naherholungsgebieten sind hierbei der Wienerwald, Schönbrunn, der Prater, die Lobau und der Bisamberg zu nennen.

Personen, die über private Außenräume (z. B. Kleingärten) verfügen, nutzen diesen bevorzugt und suchen die Innenstadt nur zur Befriedigung atmosphärisch-kultureller Bedürfnisse auf.

5 STADTSTRUKTUR UND VERSORGUNGSQUALITÄT

Die für das Projekt ausgewählten drei unterschiedlich strukturierten Beispielsräume zeichnen sich jeweils durch ihre Verschiedenheit hinsichtlich demographischer Struktur, Lage im Stadtraum sowie Topographie und bauliche Stadtgestalt aus. Daraus resultieren Differenzen bezüglich der Verkehrsinfrastruktur, der Qualität der Nahversorgung sowie dem Vorhandensein (öffentlicher) Grünflächen zu Zwecken der Naherholung. Kurz: Es bestehen Verschiedenheiten bezüglich der Versorgungsqualität hinsichtlich „Nahversorgung" und „Naherholung".

Während in den peripheren Stadträumen die Wohnnutzung und Grünflächen vorrangig sind und die Dichte der Versorgungseinrichtungen gering ist, ist im innerstädtischen Mischgebiet eine Konzentration aus „Wohnen" sowie „Gewerbe- und Dienstleistungen" gegeben. Daraus ergibt sich im Vergleich zu den beiden anderen Untersuchungsgebieten in „Neubau" eine ungleich höhere Anzahl an Nahversorgungseinrichtungen, deren Einzugsbereich teilweise (z. B. bestimmte Fachärzte) das gesamte Stadtgebiet umfasst.

Der Stadtraum am Übergang zu regional bedeutsamen Naherholungsgebieten umfasst - bedingt durch seine Nähe zum Wienerwald – zahlreiche naturnahe Erholungsgebiete, im innerstädtischen Mischnutzungsgebiet hingegen zeigt sich ein gänzlich anderes Bild: mangelnde Durchgrünung und wenige seitens der Befragten nutzbare Parkanlagen („Korridorfunktion"). Wiederum anders gestaltet sich die Situation der Naherholung in Stadtrandlage:: Hier befinden sich vielerorts große Agrar- und Gärtnereiflächen, die jedoch für die öffentliche Nutzung nicht zur Verfügung stehen. Dennoch gibt es hier zwei – über die Bezirksgrenze hinaus – sehr beliebte Naherholungsgebiete: die Blumengärten Hirschstetten und den Hirschstettner Badeteich.

Betrachtet man nun die Versorgungsqualität älterer Menschen, die auf die Nutzung öffentlicher Verkehrsmittel angewiesen sind bzw. ihre Wege zu Fuß zurücklegen, so zeigt sich, dass der innerstädtische Raum jener unter den drei ausgewählten ist, der eine gute Versorgung mit öffentlichen Verkehrsmitteln, eine ausgewogene räumliche Verteilung der Haltestellen und eine exzellente Bedienungshäufigkeit aufweist. Am Übergang zu Naherholungsgebieten hingegen ist – betrachtet man 300 Meter als fußläufig gut erreichbare Entfernung zwischen den einzelnen Haltestellen – unterversorgt. Ähnlich sieht die Situation in Stadtrand- bzw. Staderweiterungsgebieten aus. In beiden letztgenannten Stadträumen ist die Bedienungshäufigkeit tagsüber sehr gering. Ein wesentlicher Grund dafür könnte in der hohen Automobilität der (älteren) Bewohnerinnen und Bewohner liegen.

Deshalb ist es in den Stadträumen in Stadtrandlage und Stadterweiterungsgebieten sehr relevant, wo genau ein älterer Mensch wohnt: In einigen Gebieten gibt es kleine Nahversorgungszentren, die für jene, die in den Wohnhausanlagen in unmittelbarer Nähe wohnen, (fußläufig) sehr gut zu erreichen sind, während die „Hausbesitzer" in der Nähe des Hirschstettner Badeteichs entweder das Fahrrad oder das Auto nutzen müssen, um rasch die Versorgungseinrichtungen erreichen zu können.

Es lässt sich unschwer erkennen, dass jeder Stadtraum bedingt durch seine raumbezogenen Eigenschaften Stärken und Schwächen aufweist, die sich in Vor- und Nachteilen im täglichen Leben seiner (älteren) Bewohner manifestieren.

Für die Stadtplanung und Stadtentwicklung ist es nicht nur wichtig zu wissen, wo die (negativen) Knackpunkte bezüglich der Versorgungsfragen liegen, um diese zu entschärfen, sondern auch, welche Aspekte seitens der (älteren) Bevölkerung geschätzt werden, um diese möglichst zu stärken bzw. zu erhalten.

6 ROBUST IN ZEITEN DES WANDELS – GEDANKEN MIT AUF DEN WEG FÜR EINE FITTE STADTPLANUNG

Selbst wenn die Versorgungsqualität zwischen den unterschiedlichen Stadtraumtypen aufgrund deren Verschiedenheiten hinsichtlich siedlungs- und infrastrukturellen sowie sozialräumlichen, aber auch naturräumlichen Aspekten differiert, so ist unbedingt anzumerken, in Wien immer noch auf sehr hohem Niveau gejammert wird. Die Stadt hat bereits sehr viele Ideen – u. a. zur Gewährleistung der Barrierefreiheit sowie zur geordneten Nutzung vorhandener öffentlicher Grünräume durch unterschiedliche Anspruchsgruppen – umgesetzt.

Die Herausforderung, die einer zukunftsfähigen Stadtentwicklung inhärent ist, besteht darin, die Lücken und Unsicherheiten, die sich zwischen Fakten- und Vermutungswissen über (nicht) voraussichtliche Entwicklungen und Trends auftun, zu schließen und weiterhin handlungsfähig und damit robust in Zeiten des Wandels zu bleiben.

Um die Lebenssituation der heutigen und zukünftigen älteren Stadtbevölkerung weiterhin zu sichern und zu erhalten, wird es verstärkt erforderlich sein,

- sich der Gemeinsamkeiten und Verschiedenheiten in den Bedürfnissen und Anliegen der durch unterschiedliche Lebenslagen geprägte Anspruchsgruppen unter den Älteren anzunähern, um herauszufinden, wie die Angebotsplanung für diese „neuen Kollektive“ aussehen könnte.
- einen „objektiven Blick“ auf die tatsächliche Lebenssituation dieser Personengruppe im städtischen Kontext zu werfen, um die „Realität“ treffsicherer einschätzen und bewerten zu können.
- Handlungsoptionen und -prioritäten für unterschiedliche Stadtraumtypen auszuloten und in weiterer Folge festzulegen.

Viele der bisher angebotenen und umgesetzten Lösungsansätze weisen folgende Merkmale auf:

- Kleinräumigkeit und Loslösung von übergeordneten Entwicklungen
- Überschätzung der Partizipation und damit der bewusstseinsbildenden Maßnahmen im Allgemeinen
- Versuch durch Institutionalisierung teilweise Kompensation des Verlusts von räumlicher und sozialer Nähe
- sehr unterschiedliche Treffsicherheit der Maßnahmen

Zielsetzungen, die den Weg hin zu einer zukunftsfähigen Stadtentwicklung, weisen, umfassen folgende Überlegungen:

- Ausgangsbasis aller Überlegungen sollte die „Lebenslage“ („neue Kollektive“) werden, die zu einer gedanklichen Abkehr von einer Koppelung an das Alter führen sollte.
- Die Notwendigkeit des Angleichens der Geschwindigkeiten des „demographischen Wandels“ einerseits und des „stadtmorphologischen Wandels“ andererseits.
- Die Stadtplanung ist gefordert, sich wieder auf den menschlichen Maß(stab), v. a. bei Überlegungen hinsichtlich Dichtewerten, zu besinnen.
- Monotonien und „Übergrößen“ v. a. an den „Stadträndern“ und „Siedlungserweiterungsgebieten“ sollten vermieden werden.
- Damit einher geht das Überdenken von Atmosphäre und Image verschiedener (öffentlicher) Stadträume.
- Zudem sollten der Facettenreichtum und die Funktionsfähigkeit der Stadträume erhalten bleiben, was eine stadtraumdifferenzierte Betrachtungsweise notwendig macht.
- Es muss die Gestaltung von Durchmischung sowie Integration überdacht werden und letztlich wird es – aufgrund sich verändernder Raumsouveränitäten und Raumtüchtigkeiten der einzelnen Anspruchsgruppen unter den Älteren – vermehrt erforderlich sein,
- die Potenziale neuer Formen der Nahversorgung und Naherholung (Stichwort „Stufenbau der Grünordnung“) auszuloten.

Mögliche erste Schritte in diese Richtung könnten sein:

- Mut zur ehrlichen Auseinandersetzung mit der tatsächlichen Situation im (öffentlichen) Stadtraum zu zeigen
- seitens der Stadtverwaltung (bereits) ehrenamtlich tätige Personen stärker zu unterstützen
- bestehende Paradigmen zu reflektieren
- die (Interessen der) an Entwicklungsprozessen beteiligten Akteure zu analysieren und Prioritäten neu zu ordnen
- von ceteris paribus Bedingungen abzukehren und die Bedürfnisse, Nöte und Potenziale einer „Stadtbevölkerung im Wandel" zu identifizieren
- den Bedürfnissen jüngerer Bevölkerung wahrlich „mehr Raum" zu geben
- die Zukunftstauglichkeit "herkömmlicher" Lösungen zu überdenken und sich folgende Frage zu beantworten: „Würde ich die Lösungen, die ich anbiete, auch selbst nutzen?"
- den Versuch zu unternehmen, einfache" Maßnahmen ausprobieren

Das Forscher-/-innen-Team unternahm den Versuch, obige Gedanken auch konkret auf die drei ausgewählten Stadtraumtypen anzuwenden und leitete folgende Prioritäten und Zielsetzungen für die Stadtentwicklung in den beiden Handlungsfeldern Nahversorgung und Naherholung ab:

Für das Wohngebiet in Stadtrandlage und Wienerwaldnähe ergibt sich als wichtigste Priorität die Sicherung der hohen Qualität der Naherholung sowie die Mindestsicherung und – wo möglich – Verbesserung der Nahversorgung, die Schaffung eines alternativen Versorgungsangebots mit mobilen Services sowie die Sicherung der Erschließungsqualität mit Öffentlichem Verkehr. Dabei gilt es die Geländeneigung der Hanglagen zu berücksichtigen, die insbesondere für ältere Menschen Schwierigkeiten der Raumnutzung mit sich bringen.

An konkreten Maßnahmen im Bereich Nahversorgung kommen neben gezielten Förderungen für Klein- und Mittelbetriebe das Etablieren multifunktioneller stationärer Nahversorger und die Einrichtung temporärer Märkte in Frage, weiters das Forcieren (der Inanspruchnahme) von Zustelldiensten wie beispielsweise „Essen auf Rädern", der Zustell¬dienste von Supermarktketten und Lebens¬mittel¬einzelhandelsbetrieben, aber auch Apotheken¬zustelldienste.

Im Bereich Naherholung sind zudem die teils regional bedeutenden Naherholungsqualitäten in ihrem Bestand zu sichern und deren fußläufige Erreichbarkeit sowie jene mit öffentlichen Verkehrsmitteln zu verbessern und auf einen barrierefreien Zugang zu und bei den öffentlichen Verkehrsmitteln zu achten. Weiters sollten die vorhandenen (Groß-)Grünanlagen besser betreut werden z.B. durch Streuung und Reinigung der Wege besonders im Winter, rutschsichere Ausstattung der Wege sowie das Schaffen von Rast¬möglichkeiten (Bänke). Schließlich ist an das Errichten von Geländern an kritischen Stellen zu denken.

Die wichtigste Zielsetzung für die Stadtentwicklung besteht demnach in der baulich-räumlichen Integration der bestehenden Raumstrukturen, der Verstärkung des räumlichen Zusammenhalts sowie der Erhaltung und weiteren Gestaltung des hochwertigen naturräumlich-ökologischen Potenzials.

Im Mischnutzungsgebiet in dicht bebauter Innenstadtlage besteht die grundlegende Herausforderung in der Sicherung der bestehenden guten Nahversorgungsqualitäten, der Attraktivierung bzw. Anpassung des Angebots an die Bedürfnisse älterer Menschen sowie der Wahrung der Funktions- und Nutzungsmischung. Im Bereich Naherholung ist eine umfassende Verbesserung der Qualität durch gezielte Schaffung „grüner Netze" etwa in Form von Grünverbindungen und flächenhaften Grüngestaltungen möglich und nötig.

Hinsichtlich konkreter Maßnahmen im Bereich Nahversorgung bestehen vielfältige Handlungsspielräume in der „Revitalisierung" nicht mehr genutzter Erdgeschoßflächen: So könnten ehemalige, heute teils leer stehende Geschäftslokale eine Umnutzung zu „Orten der Begegnung" erfahren. Zusätzlich könnte im Zuge der Stadterneuerung und „Blocksanierung" ein Umbau zur Förderung intergenerationellen Wohnens stattfinden sowie Einheiten für betreutes Wohnen errichtet werden. Durch verbesserte Zusammenarbeit engagierter Wirtschaftstreibender könnte eine stärkere Bindung der örtlichen Kaufkraft gelingen. Das ökologische und Erholungs-Potenzial dieses Stadtraums kann durch gezielte Interventionen im öffentlichen und halböffentlichen Grünraum durch Schaffung neuer „grüner Lungen" oder die Förderung von Hofzusammenlegungen erfolgen. Zur Verringerung von Nutzungskonflikten in öffentlichen Grünräumen

bietet sich die Trennung in Funktionsbereiche sowie die Einsetzung einer generationen-übergreifenden Parkbetreuung (inkl. partizipativer Parkgestaltung) an. Darüber hinaus ist die Verbesserung der „angstfreien" Nutzbarkeit des öffentlichen Raumes mit Hilfe gestalterischer Maßnahmen, abgestimmte Ampelschaltungen und geeignete Querungshilfen zu forcieren.

An Zielsetzungen für die Stadtentwicklung ergeben sich demnach die Erhaltung, Ergänzung und Erneuerung der baulich-räumlichen Strukturen sowie die Erhaltung der Nutzungsmischung und der Nahversorgungsqualitäten, das bedeutet: ausgewogene und flächendeckende Grundversorgung in fußläufiger Erreichbarkeit. Weiters ist auf den Erhalt und Ausbau des kleinräumigen ökologischen Potenzials auf verschiedenen Maß¬stabsebenen zu achten.

Die zentrale Herausforderung für sich in Stadtrandlage befindende Gebiete besteht in der räumlichen Gestaltung der großen Naherholungspotenziale sowie der Mindestsicherung und Verbesserung der Nahversorgung, einschließlich der Sicherung der Erschließungsqualität mit öffentlichem Verkehr.

An Zielsetzungen für die Nahversorgung sind die Schaffung räumlich gut integrierter Versorgungsschwerpunkte und – fallsmöglich – die ausgewogene flächendeckende Grundversorgung in fußläufiger Erreichbarkeit ebenso zu nennen, wie der Ausbau dezentraler Nahversorgungseinrichtungen sowie die Kompensation der vorhandenen Defizite durch „neue" Services. Konkret bieten sich dieselben Maßnahmen wie für das Beispielsgebiet „Wilhelminenberg" an.

In Bezug auf die Naherholung ist abgesehen von der Sicherung bestehender Orte der Naherholung deren räumliche Vernetzung und altengerechte Verbesserung anzustreben. An konkreten Maßnahmen lassen sich etwa die Schaffung nutzbaren Grüns in Geschoßwohnbauten (Balkone und Loggien) nennen.

Die Zielsetzung für die Stadtentwicklung besteht einerseits in der baulich-räumlichen Integration der bestehenden Raumstrukturen im Sinne der Verstärkung des räumlichen Zusammenhalts durch eine behutsame Nachverdichtung und Vernetzung, andererseits in der Erhaltung sowie Gestaltung des naturräumlich-ökologischen Potenzials auf den verschiedenen räumlichen Maßstabsebenen.

7 KNACKPUNKTE ALS KONKLUSIO FÜR EINE ZUKUNFTSFÄHIGE STADTPLANUNG

Die Herausforderungen, die sich aus heutiger Sicht angesichts sich weiter ausdifferenzierender "Kollektive" innerhalb der Anspruchsgruppen (auch) unter den älteren Menschen für eine zukunftsfähige Stadtplanung ergeben werden, sind vor allem hinsichtlich ihrer quantitativen Ausprägung im Detail nicht absehbar.

Deshalb scheint es der Autorin zielführender, abschließend die „Hotspots" in Fragen zu formulieren:

Welche harten und weichen Standortfaktoren einer Stadt werden auch in Zukunft den Lebenswert welcher Anspruchsgruppen mitbestimmen?

Ist es denkbar, dass vor dem Hintergrund weiter abnehmender privater und öffentlicher Handlungsspielräume hinsichtlich der Angebotsplanung von den Paradigmen „Bringschuld der Stadt" und Qualitätssteigerung im Bereich „Betreuung und Pflege" abgekehrt werden wird? Welche Reaktionen seitens (bislang verwöhnter) Nachfrager werden zu erwarten sein?

Wie kann es gelingen, Lösungen zu kreieren, die aus heutiger Sicht nicht „modern" genug sind bzw. „altbacken" wirken? Oder: Wie ist es möglich, Ansätze zu verkaufen, die heute (noch) keine(r) will?

Was wird mit aufgeblähten Infrastruktursystemen passieren, wenn übergeordnete räumliche Entwicklungen „räumliche Nähe" wieder notwendig machen und immer weniger Systemerhalter großen diesbezüglichen Altlasten gegenüber stehen?

Wie kann es möglich sein, dass sich in ihrer Entwicklung weiterhin auf das Auto zentrierte Städte, im Krisenfall das Potenzial der Rückbesinnung auf räumliche Nähe erhalten können?

Wird Lebensqualität in der Stadt angesichts der aufgezeigten Entwicklungen langfristig vorrangig für folgende beiden „Kollektive" unter der Stadtbevölkerung – nämlich der finanziell unabhängigen Bevölkerung und (älteren) Menschen mit stabilen (familialen) Hilfs-, Obsorge- und Betreuungsnetzen – gegeben sein?

Neue Strategien und eine Datenarchitektur für das Wissensmanagement in der urbanen Pflanzenverwendung

Marcel Heins, Wolfram Kircher

(Marcel Heins, Hochschule Anhalt (FH), Strenzfelder Allee 28, D-06406 Bernburg, m.heins@loel.hs-anhalt.de)
(Prof. Dr. Wolfram Kircher, Hochschule Anhalt (FH), Strenzfelder Allee 28, D-06406 Bernburg, w.kircher@loel.hs-anhalt.de)

1 EINLEITUNG UND PROBLEMSTELLUNG

Wissen und Erfahrungen über die fachgerechte Verwendung von Pflanzentaxa (Arten, Unterarten, Sorten, Hybriden etc.) in der urbanen Pflanzenverwendung werden aktuell weitestgehend in den Köpfen der jeweiligen Akteure (Landschaftsarchitekten, Ingenieure, Mitarbeiter von Garten- bzw. Grünfächenämtern der Städte und Gemeinen, Garten-Landschaftsbauer etc.) gesammelt und durch diese eher zufällig oder projektspezifisch ausgetauscht. Weiterhin dienen Weiterbildungsveranstaltungen und Fachtagungen sowie die einschlägige Fachpresse zur Verteilung von aktuellem Wissen in der Pflanzenverwendung.

Eine Emailbefragung von Landschaftsarchitekten und Mitarbeitern von Grünflächen- bzw. Gartenämtern zeigt bereits die deutliche Tendenz, dass in den Organisationen und Unternehmen weitestgehend keine von Personen losgelöste Konzepte existieren, um Wissen und Informationen über die fachgerechte Verwendung von Pflanzentaxa zu sammeln, zu generieren und bereitzustellen. Nur vereinzelt werden z.B. sogenannte Verwendungslisten gepflegt, die Akteuren einen gemeinsamen Zugriff auf zumindest einen Teil des in einer Organistaion existierenden Wissens erlauben. Eine detailierte Auswertung dieser Umfrage steht noch aus, in der die Frage nach der Existenz von Personen losgelösten Konzepten nur eine von ingesamt sechs bzw. sieben offenen Fragen darstellt. Auch sollten z.B. Medien genannt werden, die aktuell zur Erlangung notwendigen aktuellen Wissens genutzt werden. Hier wurde das Internet sehr häufig genannt, jedoch keine spezifischen Quellen angegeben, sonder eher als allgemeine Recherche dargestellt, die sehr mühsam ist. Weiterbildungsveranstaltungen bzw. Tagungen und insbesondere Printmedien werden seitens der Aktuere immer noch das größere Gewicht zum Transfer des Wissens beigemessen, wenn es um Formen und Konzepte geht, die nicht auf eine direkte Komunikation zwischen den Akteuren abzielen.

Dieses legt die Vermutung nahe, dass tradionelle Medien und der direkte Austausch von Wissen in der Pflanzenverwendung eine Qualität aufweisen, die digtale Medien, d.h. insbesondere Pflanzendatenbanken bislang nicht erreichen. Daher können Informations- und Kommunikationstechnologien (IKT) zum Austausch von Wissen über die fachgerechte Verwendung von Pflanzentaxa nur erfolgreich sein und fachlich zielführend genutzt werden, wenn die notwendigen Informationen in der selben Qualität transferiert werden können, wie es durch traditionelle Medien oder die direkte Kommunikation zwischen Akteuren möglich ist. Gehen bei der Sammlung, Generierung und Bereitstellung von Wissen mittels IKT Informationen bzw. Daten verloren, d.h. wird das Wissen nicht vollständig abgebildet, so können zukünftig auch die zahlreichen Vorteile aktueller IKT nicht für das Wissensmanagement in der Pflanzenverwendung genutzt werden.

Daher besteht die wesentliche Aufgabe eines aktuell an der Hochschule Anhalt (FH) im Rahmen einer Dissertation gegenwärtig durchgeführten Forschungs- und Entwicklungsprojekts darin die Informations- und Datenstruktur für eine möglichst vollständige Abbildung des Wissens über die fachgerechte Verwendung von Pflanzentaxa zu analysieren. Daraus wurden Strategien und ein Datenarchitektur für das Wissensmanagement in der Pflanzenverwendung abgeleitet. Diese sollen im Projekt als Grundlage zur weiterführenden Entwicklung eines detailierten plattformunabhängigen Basis- sowie Fachdatenmodells dienen und durch das vorgesehene Prototyping eines internetbasierten Informationssystems abschliessend evaluiert werden.

2 VORGEHENSWEISE UND METHODEN

Im Projekt wurden bisher folgende Arbeitspakete abgeleistet:

- 1)Geschäftsprozess- und Informationsflussanalysen,
- 2)Analyse aktuell verfügbarer Informatonssysteme (Pflanzendatenbanken),
- 3)Analyse der Daten- und Informationsstruktur sowie
- 4)Bestimmung von Strategien und Maßgaben sowie Modellierung der Datenarchitektur.

Folgende Arbeitschritte werden aktuell durchgeführt bzw. sind in Vorbereitung:

- 5)Entwicklung eines Basis- und Fachdatenmodells,
- 6)Prototyping eines Informationssystems sowie
- 7)Evaluierung des Prototyp.

In den folgenden Abschnitten werden die bereits maßgeblich abgeleisteten Arbeitspakte kurz erläutert.

2.1 Geschäftsprozess- und Informationsflussanalysen

Im ersten Arbeitspaket wurden durch eine Geschäftsprozess- bzw. darauf aufbauende Informationsflussanalyse die wesentlichen Bereiche und Akteure ermittelt, die an der Sammlung und Generierung des Wissens beteiligt sind bzw. für die dieses bereitzustellen ist. Dabei wurde sich nicht auf das Wissen über die fachgerechte Verwendung von Pflanzentaxa beschränkt, sondern auch der Lebenszyklus von Informationen über Vegetationselemente (z.B. Vegetationsflächen, Bäume, Hecken etc.) analysiert. Aus den ermittelten Geschäftsprozessen wurde ein Modell des Wissensraumes Pflanzenverwendung und des Informationsflusses im Prozesszyklus Grünflächenmanagement entwickelt. Geschäftsprozess- und Informationsflussanalysen sowie die Untersuchung von Informationslebenszyklen bilden die wesentliche Vorrausetzung zur Bestimmung der Daten- und Informationsstruktur in einem Fachgebiet bzw. entspechenden Organisationen. (ABECKER ET AL. 2002; HEINRICH & LEHNER 2005; HEINS & PIETSCH 2008, 2009, 2010; KRCMAR 2005; LEHNER 2008)

2.2 Analyse aktuell verfügbarer Informationssysteme (Pflanzendatenbanken)

Die Untersuchung von aktuell verfügbaren Datenbanken zur Bereitstellung von Wissen über die fachgerechte Verwendung von Pflanzentaxa galt der Ermittlung des Status quo der Wissensbereitstellung. Dazu wurden vorwiegend Desktop-Systeme, die per CD-/DVD-Rom auf einem PC installiert werden, und via Internet verfügbare Informationssysteme analysiert. Die in den Systemen bereitgestellten Informationen wurden gesichtet und systematisch katalogisiert. Das betraf Arten vor allem verwendungsbezogenen/ verwendungsorientierte Pflanzenmerkmale, die das Wissen in Form von Attributen zu einem Pflanzentaxon abbilden. Die Bezeichnungen der einzelnen Attribute, ihre Skalen und Skalenwerte wurden erfasst sowie grundsätzliche Eigenschaften der Systeme dokumentiert. Erste Hinweise für die grundsätzliche Struktur, d.h. wesentliche Elemente des Wissens erarbeitet. Es wurde somit die den aktuellen Informationssystemen zu Grunde liegende Daten- und Informationsstruktur ermittelt. (BALZER 2005; HEINS ET AL. 2010; HEINS & KIRCHER 2009, HEINRICH & LEHNER 2005)

2.3 Analyse der Daten- und Informationsstruktur zur Ableitung von fachtechnischen Maßgaben

Durch das zweite Arbeitspaket konnte der Status quo der Wissensbereitstellung ermittelt werden. Da jedoch wie Eingangs dargestellt davon auszugehen ist, dass die verfügbaren Informationssysteme nicht in der Lage sind das Wissen in der notwendigen Qualität zu erfassen, abzubilden und bereitzustellen, war es notwendig weitere Medien zum Wissenstransfer in der Pflanzenverwendung zu analysieren. Aus der Gesamtheit der wesentlichen verfügbaren Medien wurden fachtechnische Maßgaben zur zukünftigen Abbildung des Wissens in Informationssystemen abgeleitet. (BALZER 2005; BIETHAHN, MUCKSCH & RUF 2004; HEINS & PIETSCH 2009, 2010, HEINRICH & LEHNER 2005; PÜRNER 1994; REUSCH & WOLF 1994)

2.4 Bestimmung von Strategien und Modellierung der Datenarchitektur

In diesem Arbeitspaket waren auf Basis der Ergebnisse der vorangegangenen Arbeitschritte die wesentlichen Strategien zur zukünftigen Entwicklung von Informationssystemen für das Wissensmanagement in der Pflanzenverwendung zu bestimmen. Die wesentlichen Elemente (Daten und Informationen) zur Abbildung des Wissens und ihre Eigenschaften wurden anhand der Modellierung einer Datenarchitektur definiert (BIETHAHN, MUCKSCH & RUF 2004; HEINS & PIETSCH 2009, 2010, HEINRICH & LEHNER 2005).

3 ERGEBNISSE

3.1 Wissensraum Pflanzenverwendung und Informationsflüsse im Prozesszyklus des Grünflächenmanagements

Auf Basis der Analyse der Geschäftsprozesse und des notwendigen Informations- und Wissensflusses zwischen ihnen wurde für die Pflanzenverwendung bzw. das Management urbaner Vegetation das in Abbildung 1 dargestellte Modell entwickelt.

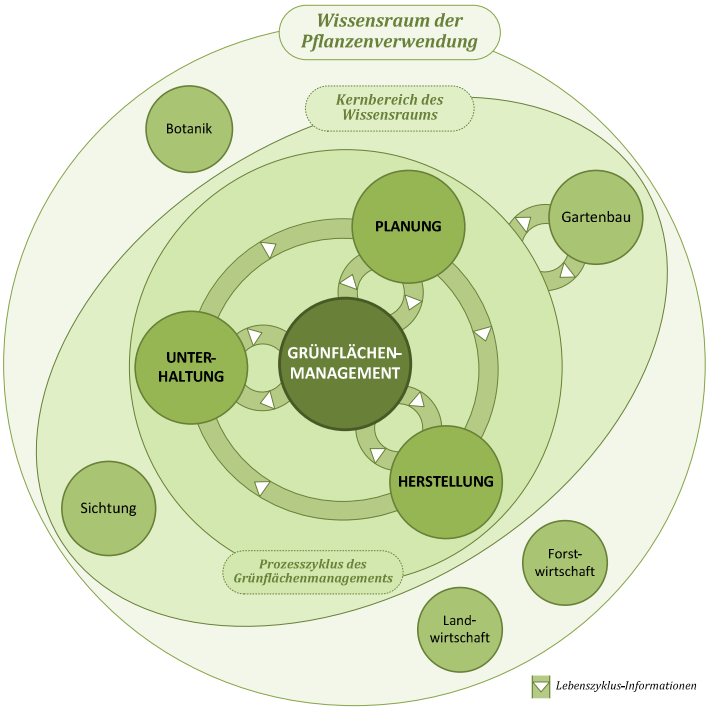

Abbildung 1: Modell des Wissensraums Pflanzenverwendung und des Geschäftsprozesszyklus Grünflächenmanagement (HEINS ET AL. 2010)

Auf Grundlage des Modells konnte ermittelt werden, dass bei allen weiteren Betrachtungen zwischen dem Informationsfluss zum Austausch von Wissen über verwendungsbezogene Pflanzenmerkmale und dem Fluss von Lebenszyklus-Informationen über konkrete Vegetationselemente/-klassen differenziert werden muss, obgleich diese semantisch miteinander verbunden sind. Diese semantischen Verknüpfungen sind jedoch bei der späteren Datenanalyse und Modellierung des Fachdatenmodells zu beachten, da wie sich zeigte daraus die Mindestinformationen zur Abbildung des Wissens abgeleitet werden können. In dem Modell (s. Abbildung 1) wird der Wissenfluss nicht gesondert dargestellt, da davon ausgegangen wird, dass dieser faktisch zwischen allen dargestellten Bereichen besteht bzw. erfoderlich ist. Lebenszyklus-Informationen über konkrete Vegetationselemente hingegen werden nur zwischen einigen Geschäftsprozessen ausgetauscht und daher im Modell gesondert abgebildet. Für das Projekt wurde die notwendige Differenzierung zwischen dem Wissen über die fachgerechte Verwendung von Pflanzentaxa (Pflanzeninformationen) und den Lebenszyklus-Informationen über konkrete Vegetationselemente (Vegetationsinformationen) an Hand der folgenden Definitionen vorgenommen (HEINS ET AL. 2010).

Pflanzeninformationen sind mehr oder weniger generelle Daten über die verwendungsbezogenen Merkmale eines Pflanzentaxons in einer Pflanzendatenbank oder einer -enzyklopädie, sowie weiteren Fachmedien. Auf Basis dieser Daten können z.B. die Pflanzenarten bestimmt werden, die zur Pflanzung bei bestimmten Standortverhältnissen geeignet sind.

Vegetationsinformationen sind die Daten, die über ein konkretes reales Vegetationselement in der Umwelt existieren, z. B. die Pflanzposition, die Pflanzenart und der Zustand eines Baumes oder beispielsweise die Pflegestufe, mit der eine bestimmte Staudenfläche zu pflegen ist. Diese Informationen werden heute bereits in zahlreichen Städten und Gemeinden in Grünflächeninformationssystemen (GRIS) für das Pflegemanagement und dessen Kostenkontrolle vorgehalten.

3.2 Status quo und Defizite vorhandener Informationssysteme

Durch die Untersuchung zahlreicher Desktop- und Internetsysteme zur Bereitstellung von Pflanzenwissen konnten wesentliche Bezeichnungen für verwendungsbezogene Pflanzenmerkmale, ihre Skalen und Skalenwerte sowie Datenarten ermittelt werden. Dabei wurden auch bestehende Defizite eruiert. Sie werden in den folgenden Abschnitten kurz erläutert und mögliche Optionen zu ihrer Minderung oder Beseitigung dargestellt.

3.2.1 Terminologiebrüche

Bei der Untersuchung der Informationssysteme wurde eine große Vielfalt an Begriffen zur Bezeichnung von Pflanzenmerkmalen (Attribute), Skalen und Skalenwerten ermittelt. Oft fehlte es an einer hinreichenden Definition der Attribute. Merkmale die originär aus der Botanik entstammen, wie z.B. Blattformen oder Blütenstände, weisen gegenüber verwendungsbezogegen Merkmalen (z.B. Ingenieurbiologische Bauweisen) eine bessere Systematik und Eindeutigkeit in der Bennenung auf. Die stichprobenhafte Analyse von Datensätzen in den Informationssystemen legt die Vermutung nahe, dass die Benennung von Attributen mit ähnlichen oder gleichen Begriffen nicht in jedem Fall auch eine einheitliche Definition der Begriffe oder der verwendeten Skala zu Grunde liegt. Das bedeutet, dass Nutzer mit zahlreichen Interpretationsspielräumen konfrontiert werden, die es ihnen überlassen, wie sie die Informationen zu bewerten haben. So wird das dichotome Attribut Bodendecker in einem Informationssystem für Pflanzenarten verwendet, die eine schnelle, relativ pflegeextensive Begrünung größerer Flächen ermöglichen. In einer anderen Datenbank hingegen ist in diese Variable auch eine ingenieurbiologische Wirkung bzgl. der Veringerung der Erosion impliziert, oder bezieht es sich ledigliche auf die Pflanzegruppe der Stauden beschreibt das Attribut z.B. die Wuchsform bzw. das Wuchsverhalten.

Oft bleibt daher unklar, wie die bereitgestelten Informationen durch die Nutzer fachgerecht zu interpretieren sind, um fachgerechte Informationen zu erhalten oder sich korrektes Wissen anzueignen. Die Harmonisierung der Begriffe, Skalen und Skalenwerte sowie ihre Benennung und eindeutige Definition ist daher eine weitere wichtige fachwissenschaftliche Aufgabe bei der Entwicklung einer integrierten Datenstruktur und Umsetzung eines Fachdatenmodells. Auch durch BOUILLON, BOISON, & SEYFANG (2002) wurde bereits die weitere Harmonisierung und Standardisierung der Terminologie für verwendungsbezogene Pflanzenmerkmale gefordert.

3.2.2 Nomenklaturbrüche

In der Botanik sind Nomenklatur und Taxonomie einem ständigen Wandel unterlegen. Aufgrund neuster wissenschaftlicher Erkenntnisse die Revision einer Gattung erfolgt, wie es z.B. bei der Gattung Aster (SCHMIDT 2004). Im Gegenzug ersetzt auch der Gartenbau bereits eingeführte Sortennamen gerne durch marketingfreundlichere Bezeichnungen. Daher existiert für nahezu jedes Pflanzentaxon eine Vielzahl an Synonymen. Für den Praktiker ist es mühsam ständig die neuen Taxa-Bezeichnungen zu lernen, und die ständig notwendige Anpassung von IT-Systemen, z.B. Warenwirtschaftssystemen in Gartenbaubetrieben oder von Pflanzendatenbanken, erzeugt in der Praxis lediglich Kosten.

3.2.3 Semantische Brüche

Unter dem Punkt semantische Brüche sollen alle Aspekte erläutert werden, die Defizite hinsichtlich einer vollständigen Abbildung des Wissens in den analysierten Informationssystemen aufzeigen. Das betrifft im Wesentlichen die das entstehen bzw. die Existenz semantischer Brüche, insbesondere durch:

- •fehlende Plausibilitätsprüfungen bzw. semantisch unverknüpfte Attribute,
- •unvorteilhafte Daten- bzw. Informationsstrukturen oder
- •fehlende (unvollständige) Daten und Informationen.

Bei der Analyse von Informationssystemen wurde ermittelt, dass bei Attributen zur Abbildung von Pflanzenmerkmalen, zwischen denen aus fachlicher Sicht semantische Beziehungen existieren, weitestgehend keine Abbildung dieser in den Informationssystemen erfolgt. Dadurch entstehen inkonsistente Daten, die zu unvollständigen und fehlerhaften Übertragung von Wissen führen können. Beispielweise war in einem Fall das Attribut „Schnittverträglichkeit“ nicht mit den Verwendungsattributen „Formschnitt“ oder „geschnittene Hecke“ verknüpft. Deutlich wurde dieses dadurch, dass für zahlreiche Pflanzentaxa zwar eine

Verwendung für Formschnitt oder eine geschnittene Hecke angegeben wurde, jedoch das Attribut „Schnittverträglichkeit“ nicht mit „Ja“ belegt war. Aus fachlicher Sicht ist jedoch die Schnittverträglichkeit eine wesentliche Voraussetzung zur Verwendung eines Pflanzentaxons für den Formschnitt oder in einer geschnittenen Hecke. Ein weiteres Beispiel für eine semantische Beziehung sind die Attribute „Salzverträglichkeit“ und „Straßenbegleitgrün“. Das heißt es erfolgt durch derartige Informationssysteme keine Prüfung der fachlichen Plausibilität der eingegebenen Daten, was die Qualität des abgebildeten Wissens verringert, aber auch eine automatisierte Ableitung einzelner Merkmale bei der bestimmten Ausprägung anderer verhindert. Dieses erhöht ggf. wiederum die aufzuwendenden Ressourcen zur Pflege und Aktualisierung der Informationssysteme.

Pflanzennamen	Licht	Nährstoffgehalt	Sommerfeuchte
Stachys byzantina	vollsonnig	sehr arm bis arm	trocken bis frisch
Stachys byzantina 'Cotton Boll'	vollsonnig	sehr arm bis arm	trocken bis frisch
Stachys byzantina 'Sheila McQueen' -> Stachys byzantina 'Co	vollsonnig	sehr arm bis arm	trocken bis frisch
Stachys byzantina 'Silver Carpet'	vollsonnig	sehr arm bis arm	trocken bis frisch
Stachys grandiflora 'Superba'	sonnig bis leicht schattig	normal bis hoch	trocken bis sehr frisch
Stachys lanata -> Stachys byzantina	vollsonnig	sehr arm bis arm	trocken bis frisch

Abbildung 2: Informationen über die Standortansprüche/-toleranzen von Pflanzentaxa in der Pflanzendatenbank PLANTUS (Screenshot) (BÖDECKER & KIERMEIER 1998)

Die Ermittlung unvorteilhafter Daten- und Informationsstrukturen, die aus fachlicher Sicht keine vollständige Abbildung des Wissens ermöglichen, bilden ein weiteres Defizit. So werden in nahezu allen Informationssystemen, die Daten über den durch ein Pflanzentaxon physiologisch tolerierten Bereich von Standorteigenschaften unabhängig voneinander vorgehalten. Jede Standorteigenschaft wird dort durch die Angabe der tolerierten Ausprägungen separat auf einer Skala betrachtet (s. Abb. 2). Informationen über eine differenzierte Bewertung bestimmter Kombinationen von Standortparametern werden nicht abgebildet, obwohl das „Gesetzt der relativen Standortkonstanz“ besagt, dass die Ausprägung einer Standorteigenschaft einerseits den physiologisch tolerierten Bereich anderer Standorteigenschaften zusätzlich begrenzen, andererseits aber die suboptimale Ausprägung einer von mehreren Standorteigenschaften durch besonders vorteilhafte Ausprägungen anderer essenzieller Standorteigenschaften kompensiert werden kann (BORCHARDT 1999; HEINS ET AL. 2010; WALTER & BRECKLE 1999). Für die Pflanzenverwendung ergeben sich aus dem Gesetz erheblich mehr Verwendungsmöglichkeiten als für viele Arten in gängigen Pflanzendatenbanken recherchierbar sind. Es können aber auch viele Unsicherheiten bei der standortgerechten Auswahl von Pflanzentaxa daraus resultiren, die zu Planungsfehlern führen. Es liegt auf Basis der aktuell nutzbaren Daten an der Interpretation des Nutzers eines Informationssystems, ob er eine bestimmte Kombination von Standortparametern als optimal ansieht. Die Entwicklung einer geeigneten Strategie zur Beseitigung dieses Defizits und ihre Umsetzung in ´der Datenarchitektur war daher ein weiterer wesentlicher Punkt der folgenden Arbeitschritte.

Durch zahlreiche Fachexperten wird immer wieder bescheinigt, dass sich das Wissen über die fachgerechte Verwendung von Pflanzentaxa nur sehr schwer verallgemeinern lässt, sondern immer einen Bezug zur Region oder dem Ort in bzw. an dem die Erfahrung gesammelt wurde besteht. Verfügbare Informationssysteme verallgemeinern jedoch sehr stark und eine räumliche Bezugsgröße für das bereitgestellte Wissen ist z.B. Mitteleuropa. In der Praxis vertrauen daher die Akteure lieber auf ihre über Jahre oder sogar Jahrzehnte gesammelten Erfahrungen, da die räumlichen Bezugsgrößen in den Informationsystemen zu groß gewählt sind. Eine Erfassung und Bereitstellung einer stärkeren räumlichen Differenzierung für das bereitgestellte Wissen ist in den aktuell verfügbaren Informationssystemen nicht möglich bzw. informationstechnisch nicht vorgesehen. Daher wird eine grundsätzliche Strategie zur stärkeren räumlichen Differenzierung von Pflanzenwissen erarbeitet. Bei der Entwicklung des Datenarchitektur wird diese Maßgabe ebenfalls berücksichtigt und entsprechende Vorrausetzungen geschaffen, um die fehlenden Daten und Informationen für den räumliche Bezug eines Datensatzes über verwendungsbezogene Pflanzenmerkmale anzugeben. Weiterhin betrifft der Punkt fehlende Daten und Informationen auch die Integration eines Attributes zur differenzierten Bewertung (optimal bis ungünstig) bestimmter Kombinationen von Standortparametern, die in Informationsystemen bislang auch nicht möglich ist. Es sind keine Informationen über ungünstige Standortfaktoren verfügbar bzw. nur aus der Interpretation heraus, dass alle nicht angegeben Ausprägungen von Standortparametern ungünstig sind.

3.3 Fachtechnische Maßgaben für das Wissensmanagement

Aufbauend auf die Ergebnisse der vorangegangenen Arbeitschritte wurden durch eine umfasendere Daten- und Informationsanalyse Maßgaben für das Wissensmanagement in der Pflanzenverwendung formuliert. Dabei wurde deutlich, dass eine Zusammenführung vorhandener Methoden und Vefahren der Wissens- und Informationslogistik im Grünflächenmanagement bzw. in der Pflanzenverwendung möglich ist, um bereits einige aufgezeigte Defizite zu mildern oder sogar zu beseitigen. Weiterhin wurden die Struktur und grundsätzliche Elemente des Pflanzenwissens ermittelt, charakterisiert und darauf aufbauend als Datenarchitektur modelliert.

3.3.1 Basis- und/oder Zielvariablen (Basisattribute und abgeleitete (derived) Attribute)

In Abschnitt 3.2.3 wurde dargestellt, dass zwischen verschiedenen Attributen zur Beschreibung von Pflanzen- bzw. Verwendungsmerkmalen semantische Beziehungen bestehen, die in Pflanzendatenbanken bisher nicht abgebildet werden können oder abgebildet werden. Als Beispiel wurden die Variablen „Schnittverträglichkeit“, „geschnittene Hecke“, und „Formschnitt“ angeführt. Für die Datenarchitektur bedeutet dieses, dass zwischen Basis- und Zielvariablen (derived attributes) zu unterscheiden ist. Ein abgeleitetes Attribut kann dabei auch gleichzeitig als Basisvariable für eine weitere Zielvariablen fungieren. Weiterhin kann auch die spezifische Kombination der Ausprägung mehrerer Basisvariablen die Ausprägung einer Zielvariablen bedingen. So ist beispielweise die Ausprägung „Ja“ des dichotomen Attributs „Schnittverträglichkeit“ eine Vorrausetzung dafür, das bei einem Pflanzentaxon die Variable „geschnittene Hecke“ mit „Ja“ ausgeprägt sein kann.

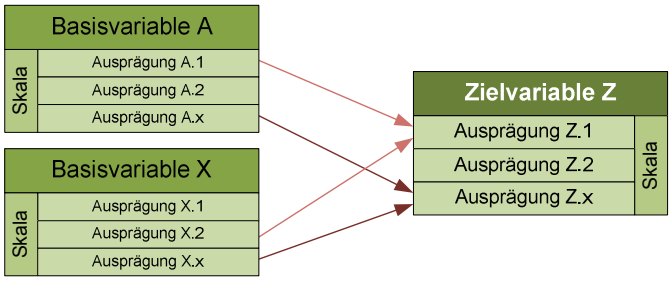

Abbildung 3: Abhängigkeit zwischen der Ausprägung von Basis- und Zielvariablen zur Umsetzung fachsemantischer Beziehungen

3.3.2 Verwendungseignung und Objektarten des Grün- bzw. Freiflächenmanagements

In vorhandenen Pflanzendatenbanken werden für Pflanzentaxa Verwendungseignungen angegeben. So ist ein bestimmtes Taxon z.B. als Straßenbegleitgrün geeignet, andere für geschnittene Hecken, zur Pflanzung auf Spielplätzen oder in Parkanlagen. In Grünflächeninformationssystemen (GRIS) werden Informationen zu Grün- und Freiflächen einer Kommune auf Basis eines Objektartenkatalogs gesammelt und bereitgestellt. In dem Leitfaden zur Erstellung und Fortschreibung eines Grünflächeninformationssystems (GALK-DST 2009) oder dem OK Frei (FLL 2009) existiert eine hierachische Systematik für Vegetationsklassen (z.B. Sträucher, Hecken, Beete). Die Klasse Hecken ist wiederum in die Unterklassen „Freiwachsende Hecken“ und „Formhecken“ untergliedert. Dieses ist nur ein Bespiel dafür, dass die Systematik einer Grünflächendatei in besonderer Weise mit den Verwendungseigenschaften korrespondiert, die für ein Pflanzentaxon in bestehenden Pflanzendatenbanken angegeben werden können. Jedoch ist die Terminologie nicht standardisiert. Weiterhin existiert in den Leitfaden zur Erstellung und Fortschreibung eines Grünflächeninformationssystems noch eine übergeordnete Systematik, die ein eigenes System darstellt. Sie wird dort als Objektdatei bezeichnet und enthält z.B. die Klassen Grün- und Parkanlagen, Spielplätze, Straßenbegleitgrün etc., Hausgärten können ebenfalls in diese Liste eingereiht werden.

Zur Angabe der Verwendungseignung eines Pflanzentaxons müssen drei Sachverhalte unterschieden werden: 1. Urbane Einrichtungs- bzw. Freiflächentypen, 2. Die Klasse (Typ einer Vegetationsfläche bzw. eines -elements und 3. Funktionen und Dienstleistungen einer Vegetationsklasse. Beispielsweise würde ein Pflanzentaxon für eine Formhecke auf einem Spielplatz geeignet sein, wenn es keine giftigen Pflanzenteile besitzt und schnittverträglich ist. Eine Kombination der drei Daten-Elemente soll in der zu entwickelnden Datenarchitektur als Anwendungsfall bezeichnet werden (s. Abb. 4).

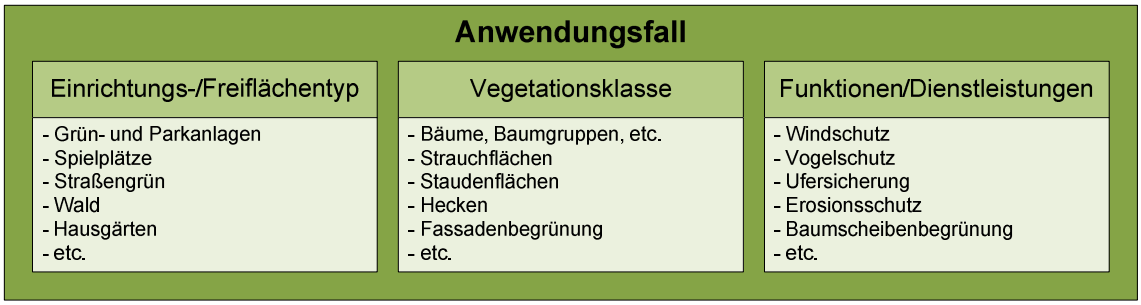

Abbildung 4: Datenelemente/-architektur eines Anwendungsfalls in der Pflanzenverwendung

3.3.3 Bewertung der Kombination von Standortparametern und der Verwendungseignung

Die Eignung eines Pflanzentaxons für einen bestimmten Anwendungsfall lässt sich aus verschiendenen Basisvariablen ableiten, die dafür eine bestimmte Ausprägung haben müssen. Diese Eignung wird in verfügbaren Pflanzendatenbanken als dichotome Variable mit „Ja“ oder „Nein“ angegeben. Diese Form wird auch in die Datenarchitektur umgesetzt werden, da die Einführung einer mehrstufigen Skala, z.B. des Parameter „bedingt geeignet“ bei Nutzern nur zu Verwirrungen führen würde.

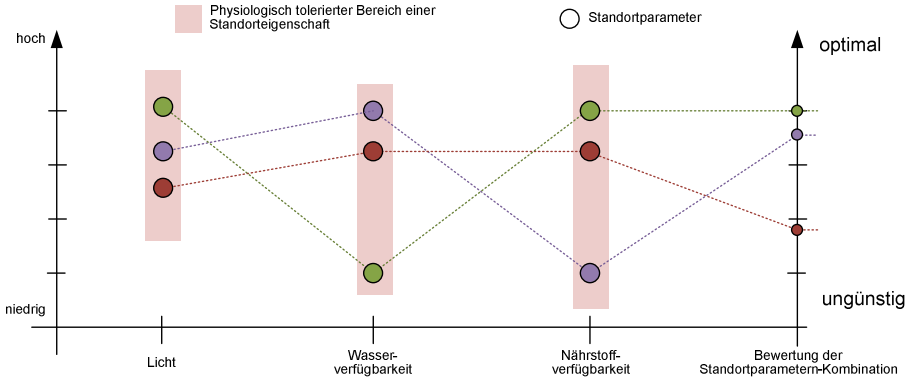

Abbildung 5: Fiktive Bewertung der Lebensbedingungen für ein Pflanzentaxon anhand der Bewertung der spezifischen Kombinationen von Standortparametern (HEINS ET AL. 2010)

Eine Bewertung der Ausprägung von Standortattributen (Bodenfeuchtigkeit, Licht etc.) ist aktuell nicht realisiert. In den Datenbanken werden die einzelnen Standorteigenschaften separat betrachtet (siehe 3.2.2) und die Angabe ungünstiger Standortbedingungen ist nicht möglich. Diese Informationen fehlen gänzlich, obwohl dieses Wissen in der Praxis ggf. bereits gesammelt wurde. Es ist somit nicht nachvollziehbar ob ein Pflanzentaxon bestimmte Standortparameterkombinationen nicht toleriert, weil diese in einem Informationssystem nicht aufgeführt sind oder weil keine Erkenntnisse darüber vorliegen. In die Datenarchitektur ist daher die Bewertung von spezifischen Standortparameter-Kombinationen zu integrieren hinsichtlich der Lebens-/Wachstumsbedingungen für ein Pflanzentaxon (siehe Abb. 5).

3.3.4 Differenzierung der Ausprägung von Pflanzenmerkmalen

Je nachdem an welchem Standort ein Pflanzentaxon gepflanzt wird oder für welchen Anwendungsfall dieses zum Einsatz kommt, können die Ausprägungen von Pflanzenmerkmale entscheidend von denen des Naturstandortes abweichen. In der Datenarchitektur muss daher zwischen unabhänhigen (statischen) und abhängigen (dynamischen) Attributen unterschieden werden. So erreicht z.B. ein Taxon an seinem Naturstandort eine durschnittliche Wuchshöhe von 25 m. Wird das Taxon als Straßenbaum gepflanzt, wird diese Wuchshöhe auf Grund der extremen Standortbedingungen gff. niemals erreicht werden. Die unterschiedlichen Angaben in verschiedenen Pflanzendatenbanken, sowie weiteren Medien legen die Vermutung nahe, dass hier je nach Kenntnissstand die Wuchsgröße vom Naturstandort oder für eine bestimmte Verwendung angegeben wurde. Verwendete Bezugsgrößen (Anwendungfall, Standort etc.) eines Pflanzenmerkmals fehlen jedoch oft völlig. Pflanzenattribute, die in ihrer Ausprägung in besonderer Weise vom Anwendungfall oder weiteren Größen beeinflusst werden können, werden in der Datenarchitektur als dynamische Attribute bezeichnet.

3.3.5 Räumliche Differenzierung von Pflanzenwissen

In 3.2.3 wurde bereits erläutert, dass eine räumliche Differenzierung der Ausprägung von Pflanzenmerkmalen in bestehenden Pflanzendatenbanken nicht oder nur sehr eingeschränkt möglich ist, obwohl sich bestimmte Erfahrungen nicht für eine sehr große geographische Bezugsgröße (z.B. Mitteleuropa) verallgemeinert lassen. Die Kategorie „Lokalsorte“ bei der Staudensichtung (HERTLE 2010) zeigt, dass bestimmten Taxa nur für ein begrenztes geographisches Gebiet hervorragende Verwendungseigenschaften bescheinigt werden. Auch die Straßenbaumliste der GALK (GALK-DST 2006) weist immer wieder Angaben zu regionalen Ausprägungen von Pflanzenmerkmalen aus (z.B. Anfälligkeit für Krankheiten). Eine konkrete Benennung von räumlichen Bezugsgrößen erfolgt jedoch nicht. In die Datenarchitektur ist daher eine Komponente zu implementieren, durch die eine räumliche Verortung (bzw. Klassifizierung) von Pflanzenwissen erfolgen kann. Eine flächendeckenden Systematik für Raumklassen in der Pflanzenverwendung wäre darauf aufbauend eine hervorragende Grundlage zur Ermittlung der Möglichkeit zum synchronen oder asynchronen Austausch von Pflanzenwissen zwischen verschiedenen Orten bzw. Regionen (s. Abb.6; HEINS ET AL. 2010).

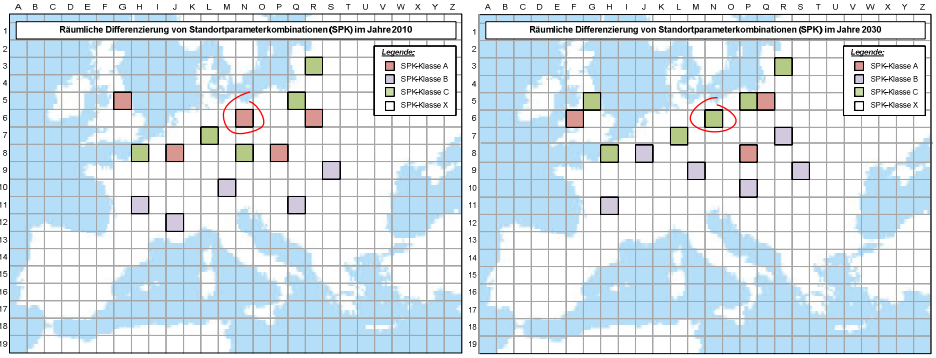

Abbildung 6: Fiktive, vereinfachte Darstellung der asynchronen Änderung von Raumklassen der Pflanzenverwendung in unterschiedlichen Regionen im Laufe des Klimawandels

4 FACHTECHNISCHE STRATEGIEN UND DATENARCHITEKTUR

Im Folgenden werden als Zusammenfassung der bisherigen Forschungsergebnisse die Strategien zur Umsetzung zukünftiger Pflanzendatenbanken benannt und kurz erläutert. Zusätzlich wird noch darauf eingegangen, in welchem Maße diese im Projekt umzusetzen sind und damit gleich ein Ausblick auf das weitere Vorgehen gegeben. Die modellierte Datenarchitektur stellt einen wesentlichen Meilenstein der bisherigen Forschungsaktivitäten dar, auf den zielführend die weiteren geplanten Arbeitsschritte abgeleistet werden können.

4.1 Fachtechnische Strategien

4.1.1 Eindeutiger Identifier für Pflanzentaxa

Eine zentrale informationstechnische Verwaltung, Pflege und Bereitstellung der Taxonomie und Nomenklatur ist eine wichtige Maßgabe, um zukünftig nutzerfreundliche Informationssysteme zu entwickeln. Die Einführung eines einheitlichen Identifier (World-Wide-ID) für Pflanzentaxa unabhängig von wissenschaftlichen oder sonstigen Bezeichnungen; sowie ggf. Entwicklung eines zentralen Web-Service. Ein Webservice, der die Informationen im ZANDER (SEYBOLD et Al. 2009) mit den Artikelstämmen (BSG 2010), z.B. nach der Art und Weise des „Universal Biological Indexer and Organizer (uBio)“ (MBL 2010) verknüpft, wäre hier eine zukunftsfähige Option. Die Bezeichnungen für ein Pflanzentaxon sind lediglich Attribute dieses Fachobjekts. Die Entwicklung eines entsprechenden Webservice wird nicht in diesem Projekt abgeleistet werden können, jedoch sind die Möglichkeiten einer zukünftigen Einbindung derartiger Services bereits im datentechnisch vorzusehen. Die Umsetzung eines entsprechenden Systems ist nicht Bestandteil dieses Projekts, wird jedoch aktuell als weiterführendes Vorhaben vorbereitet.

4.1.2 Bewertung von Standortparameter-Kombinationen

In zukünftige Pflanzendatenbanken ist die Bewertung von Standortparameter-Kombinationen daten- und softwaretechnisch vorzusehen. Die Bewertung muss weiterhin mit einem räumlichen Attribut verknüpft

werden, damit die Möglichkeit geboten wird, eine räumliche Bezugsgröße für die Gültigkeit dieses Wissens anzugeben.

4.1.3 Einführung des Attributes Anwendungsfall

Verwendungseigenschaften bzw. -eignungen werden in zukünftigen Pflanzendatenbanken als Anwendungsfall definiert. Ein Anwendungsfall wird durch die Ausprägung der Attribute Einrichtungs-/Flächentyp, Vegetationsklasse und Funktion/Dienstleistung charakterisiert. Diese Attribute wie auch der Anwendungsfall selber sind Zielvariablen (derived attributes), die eine semantische Verknüpfung zu der Ausprägung von Basisvariablen besitzen.

4.1.4 Statische und dynamische Attribute

Es ist zwischen statischen und dynamischen Attributen (Pflanzenmerkmalen) zu unterscheiden. Dynamische Attribute müssen eine Verknüpfung zu den Attributen besitzen, die einen Einfluss auf Ihre Ausprägung haben können. Das sind insbesondere der Anwendungsfall und eine geographische Bezugsgröße.

4.1.5 Terminologie und Abbildung der Semantik

Alle Attribute und ihre möglichen Ausprägungen auf einer Skala sind eindeutig zu benennen. Es ist weiterhin festzulegen, ob es sich um ein Basisattribut oder ein abgeleitetes Attribut (derived attributes) handelt. Die semantischen Bezüge zwischen Attributen und ihren Ausprägungen sind datentechnisch zu definieren und umzusetzen. So ist z. B. an Hand eines Entscheidungsbaumes festzulegen, welche Vorrausetzungen (Ausprägung von Attributen) erfüllt sein müssen, dass ein Pflanzentaxon für einen bestimmten Anwendungsfall geeignet ist. Das bedeutet. dass die Ausprägung von Basisattributen hinsichtlich der daraus abzuleitenden Ausprägung weitere Attribute möglichst eindeutig zu definieren ist.

4.2 Datenarchitektur

Auf Grundlage der hergeleiteten Maßgaben und der aufgestellten Strategien wurde ein Modell zur Abbildung von Pflanzenwissen in der Pflanzenverwendung und im Grünflächenmanagement entwickelt (s. Abb. 7). Diese Datenarchitektur ist ein wichtiger Meilenstein und eine wesentliche Grundlage zur zielführenden Ableistung der nächsten Forschungs- und Entwicklungsschritte. Das sind insbesondere die Entwicklung und datentechnische Umsetzung eines detailierten Fachdatenmodells sowie das Prototyping eines zukünftigen Informationssystems für das Wissensmanagement in der Pflanzenverwendung.

1 ABSTRACT

Istanbul has always been the core of different civilizations in history. As the capital city of the Ottoman Empire, Istanbul's modern place within the world economy began in the late eighteenth century with the disintegration of the Ottoman Empire and the growth of modern European capitalism. Throughout its history, Istanbul has played a primary role in its region. In the 19th century and into the 1920s, the city was a center for transportation, bonded warehouses, trade and stock exchange.

Between 1923-1950, the city of Istanbul loses its administrative and economical power due to the new status of Ankara as -the new capital of Turkey- and new economical decisions.

After the 1960s, Istanbul has become a Metropolitan City, which is the window opening of Turkey into the global market and carrying the burden of national economy. Istanbul is in the Marmara Region which is the most developed & modern part of the country. Istanbul is the city where the largest industrial companies of Turkey are accommodated.

International capital sees Istanbul as likely to be the command and control center for the Balkans, the Middle East, the Black Sea Region, and some of the Central Asian Republics of the former Soviet Union. From this point of view, it has a strategic geographical location which promotes competitive economy at EU level.

In this paper we study the relationships between industrial decentralization process and the vision of Istanbul Metropolitan Plan for 2023.

The focus of the research case is the relocation of the shipbuilding industrial site in Istanbul Metropolitan Area.

These kinds of industrial regeneration projects in Istanbul should be seen as a means not only to convert the areas into more attractive spaces but also to regenerate the economy of both the city and the local region. However, creating new functions and land uses will re-image the city and have effects on the local labor market, and also cause challenges to communities in the new location.

Keywords: Industrial regeneration, vision of the Istanbul Metropolitan plan, public-private partnerships, shipbuilding industries.

2 URBAN DEVELOPMENT AND INDUSTRIALIZATION

Urbanization is the most prominent of the contemporary economic and social phenomena. Since the first settlements appeared, the most complex organism created by humankind has been city. The urban population quadrupled since 1950. Therefore, it is possible to call this age as the age of “urban revolution” [UN, 1987].

Before the Industrial Revolution in the 19th Century, cities had been places in which agriculture and trade were prevalent. Humankind - especially after the Industrial Revolution- started to change the nature of its relationship with the nature which had existed from ancient cities until medieval trade cities in favor of himself.

Industrialization, which is an “activity that creates city” [E.Tümertekin, 1994], had two kinds of influences on settlements. The first one was that old cities having traditional textures have expanded with the effect of industrialization. The second influence was the emergence of new cities. Settlements that used to contain a few houses have transformed into industrial cities. The city of Istanbul can be given as an example of the cities that expanded with the effect of industrialization. Istanbul has become a “monstrous industrial city” [M.Güvenç, 1993] with the effect of industrialization especially after 1950.

Since industrial operation requires large numbers of labor force, industrialization, at first, emerged as a process of large concentration of population. Along with the increase in population, specialization of labor and the emergence of the division of labor is one of the effects of industrialization. In addition, rapid

industrialization and population growth, mechanization of agriculture, concentration of production and consumption in big cities have created several problems for the social and physical environment.

The geographical position of the city plays an essential role not only in the location of industrial operations but also in covering inhabitants' needs. In this respect, along with the geographical conditions of the city, the conditions related to the social, economic and transportation order that emerge within the city and its hinterland are of importance. Within this web of relations, the city put a planned growth on the agenda in that period. The aim of physical planning which enables the best allocation of economic investments in space is to determine the best relations between all functional elements of the newly developed or transformed urban space. In other words, its aim is providing the best site selection for new investments, allocating new transportation networks, new housing areas and new industrial operations in the correct way, and organizing the growth of cities and regions.

Though the view of physical planning in its narrow sense on the city is explained in this way, in the recent two decades, the idea that the city based only on economic growth is not sustainable and the ecological and social developments should also be taken into consideration has become prominent.

Along with the developments in the essential logistical activities such as raw material supply, product distribution and food transportation, the presence of social and ecological problems brought about by industrialization and urbanization rendered the notion of sustainable development prominent. Assessing the reactions given firstly by the nature itself and then by social groups to the environmental problems created by the growth based only on industry has become important issues.

Urban development is generally observed before the emergence of a healthy and diverse economical base which would provide housing areas, infrastructure and employment. In many places, problems are related to the inconsistencies between agricultural and urban development strategies which do not conform to industrial development.

The network composed of the city and its countryside encompasses the all aspects of the environment of social life. At the international level, prominent cities of the world form a network in terms of the site selection of investments and the production and selling of many products and services. These centers become the first ones to join this network through airports, railroad terminals and ports, and their communication facilities. New technologies come to these areas first. Cities, only when they are strongly attached to this network, can attract investments intended for global markets and production goods.

As a result of the competition created by the possibility to access to global markets, economies rapidly cease being industry-based and start to concentrate on services sector.

Places where the production will be performed during the process and the roles that the actors of the process should undertake are defined within these relations. Especially firms' site selection decisions have started to have implications beyond national urbanization/settlement policies.

Within the framework of the relations between global powers and local dynamics, spatial policies intended for urban territories have brought about the process of organizational restructuring. [P.Healey, 2004]

"Globalization is often seen as a process of homogenization. While this idea can be admitted in the cultural sense, it is difficult to argue the same in the economic sense. The primary reason of the emergence of global markets which enable free movement of capital and other production factors between countries is different characteristics of different geographies. Globalization of economic activities becomes possible since employee wages, specializations, production infrastructures, political and economic risks in different geographies become available to the whole world." [M.Godinez, 1999]

The desire of capital groups for opening to other countries –search for new markets- has brought about new production relations.

International capital's desire for creating new markets has created a new structuring. International capital establishes connections with firms in several countries. It creates a main power in the center and small components connected to that center. Within this formation, international financial centers –with their several historical characteristics- direct world markets. [S. Sassen, 1999]

Globalization ignores the nation state and attaches importance to cities and regions. Therefore, national and international economies are turning into regional metropolitan-based economies. [L.Berg, E.Braun, J. Meer, 1996]

In conclusion, cities in this new competitive atmosphere try to take decisions for their futures under;

- Economic globalization
- Transition to the information society
- Metropolitan competition
- Regional integrations
- Serious environmental problems.

There are some strong indications of radical changes in urban employment patterns as well. In many "mega-city regions" around the world, deindustrialization and disappearance of basic industrial sectors and rise of professional services have placed serious challenges of the politicians' agendas in closing the skill gap between old-fashioned and new job areas (Hall, 2009). The major reflection of this transition in spatial arena is mostly the relocation of old industrial facilities and low value added services to the periphery of the metropolitan areas.

According to Healey (Healey, 2008) as well, city-regions are now becoming "critical institutional arena" in the allocation of growth-promoting development investment of the governments'. In such a policy shift, the main objective is not "leveling up" the regions but instead, creating a competitive environment within the regions to enhance the 'economic dividend' to maximize the public welfare.

It is not possible to consider the Istanbul Metropolitan Area separate from these developments. It will be accurate to examine the vision of the 1/100,000 scaled Istanbul Metropolitan Plan, which was approved in 2009, related to industrial areas and -in particular- to shipbuilding regions within the framework of urban/regional competition. Main discussion topics could be; spatial size, site selection, hinterland, technological innovation, environmental conditions, technical and social infrastructure, institutional capacity, political atmosphere, legislation, economic development, its relations with the city and region in which its located.

2.1 The Shipbuilding Sector in the EU Negotiation Process

The European Union is an important social, economic and political area in which Turkey has desired to join since the Ankara Agreement signed in 1963. Although the process has provided Turkey with the membership status, there is a controversy on the date Turkey will become the full member of the EU. Especially in recent days, it is being noticed as the chapters of the accession process come up that the membership process is a very difficult path.

However, Turkey is recently making increasing efforts to reach the norms and standards of the EU in terms of development dynamics. One of the negotiation chapters in Turkey's accession process is on "Enterprises and Industrial Policies". [URL-1] Despite a competitive industrial sector is targeted, the Turkish shipbuilding sector's share in the world is below 1% [URL-2].

The shipbuilding sector is one of the important and strategic branches of industry for EU member and candidate countries. More than 300 shipbuilding zones exist throughout the EU. Around 40 of these shipbuilding play an active role in the global market for large sea-going vessels. The shipbuilding sector in the Europe creates 140.000 direct and 400.000 indirect jobs.

Around 80% of the world shipbuilding sector is concentrated in Japan, South Korea, China and EU countries. [URL-3] This situation causes the development of a strategy directed especially towards the Asia-Pacific countries in the EU. In general, the EU has already defined the strategy to form "the most competitive economy of the world" with the Lisbon Declaration.

The EU's target for shipbuilding zones is as follows; "The EU is seeking to rationalize the shipbuilding industry by means of a controlled cut-back in capacity (a quantitative adjustment). While the workers made redundant should be retrained, the EU should obviously maintain some reserve capacity for strategic, social, economic and industrial reasons. Assistance for existing shipbuilding should concentrate on modernizing and

diversifying production machinery and on improving productivity and competitiveness (a qualitative adjustment).” [URL-4]

Therefore, what needs to be understood is that, in order to improve competitiveness, objectives that are in accordance with the EU and aimed at ensuring the modernization, efficiency and rationality of shipbuilding zones should be set.

2.2 Development Plan IX (2007–2013) and the Shipbuilding Sector

When settlements are planned in countries who principally adopted the development plan and making legal regulations accordingly, the area is assessed by considering employment possibilities in that area and the natural and cultural characteristics of the environment. The area is generally assessed with its characteristics, its importance and potential in the country, its functions, and the quality and potential of the future labor. Decisions related to the development of a specific region in plans depend on the region’s natural characteristics, social structure, and economic activities located in it.

Turkey has already included the principle of planned development in its legal regulations and prepared development plans accordingly, the first of which was prepared by the State Planning Institute (SPI). Today, the Development Plan IX which covers the period of 2007–2013 is in effect.

The legal and institutional structure of a plan hierarchy starting from macro plan principles that define the order of the country and direct investment decisions has already been established in order for Turkey to develop through regional-level studies and decisions in line with Turkey’s general settlement objectives.

High level plan principle decisions are determined through five-year development plans and during these plans are prepared; Special Expert Commission Reports give advices to the state sector and investors about the priorities and characteristics of the main principles in plans and special investments

In this respect, the shipbuilding activities located in the Istanbul Metropolitan Area and the shipbuilding and shipping sectors in the city of Yalova were analyzed and assessed in terms of high-level country plan decisions.

The SPI Development Plan IX (2007–2013) Shipbuilding Industry Special Expert Commission Report examines the current situation of Turkish Shipbuilding.

When the SPI Development Plan IX (2007–2013) Shipbuilding Industry Special Expert Commission Report (2006) is analyzed, it is stated that previous decisions are prevailing and new decisions will follow the same direction.

In the period of the Five-Year Development Plan VIII (2000–2005), it is stated that, based on the rapid increase in shipbuilding in the world and Turkey which started in 2002–2003, the capacity of shipbuilding has rapidly increased in the years of 2003–2004 (Fig. 1). Therefore, the Development Plan IX recommends several visional improvements towards increasing the global competitiveness of this intense activity in the sector.

The target “Establishment of higher capacity shipbuilding in order to increase shipbuilding competitiveness” was included in the Shipbuilding Industry Special Expert Commission Report.

	2003				2004			
	Delivery	%	New-Order	%	Delivery	%	New-Order	%
Turkey	155.440	0.29	400.000	0.38	293.000	0.51	650.000	0.70
World	53.100.00	100	104.700.000	100	57.400.000	100	93.100.000	100

Fig. 1: Values –in DWT- of delivered ships and new orders taken in the years of 2003–2004 in the world and in Turkey (Source: SPI, 2006)

As the above figure suggests, amounts of new orders and deliveries have increased both in numbers and proportion in recent years. It is inevitable for this increase to bring about capacity increase. Similarly, the projection that belongs to the period of the Development Plan IX suggests a linear increase in production until 2013 (Fig.2)

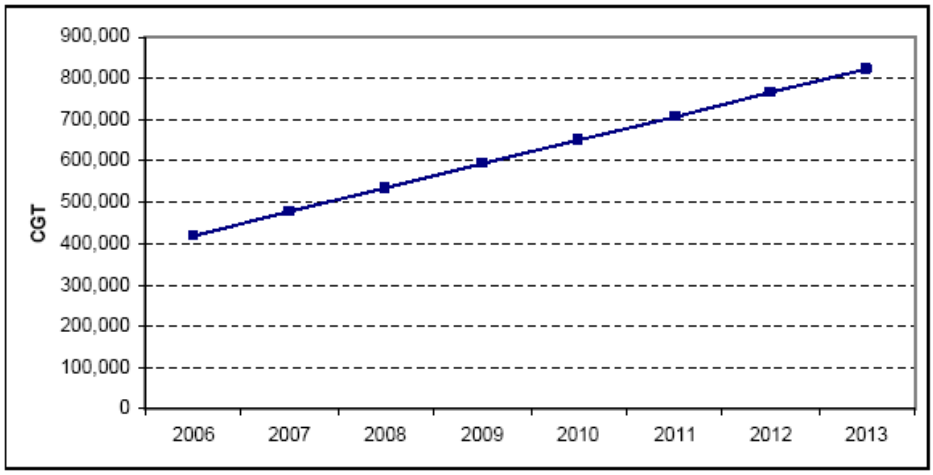

Fig. 2: The projection of ships that will be constructed in Turkish shipbuilding between the years of 2006–2013 in CGT. (Source: SPI, 2006)

Shipbuilding in Turkey operating in shipbuilding sector can be grouped under three headings: private sector shipbuilding, public sector shipbuilding and military shipbuilding. The most prominent one of the areas around which private sector shipbuilding clustered is the Tuzla District in the Marmara Region.

The Tuzla Private Sector Shipbuilding Zone was formed after; Tuzla-Aydınlı Cove was assigned as the "Shipbuilding and Subsidiary Industry Zone" by the decision of Council of Ministers Nr. 6/12421, dated September 22, 1969, sites were allocated to the entrepreneurs who would invest in the Tuzla Shipbuilding Industry Zone and the easement right were granted by the Ministry of Finance for 49 years.

Currently operating in the zone are 31 shipbuilding oriented firms, 13 wet docks, 1 dry dock, and 7 wood-fiberglass-steel vessel factory. In this zone, it is possible to construct ships up to 80,000 DWT and to dry-dock ships up to 300,000.

Due to increasing shipbuilding demands, firms who could not increase their capacities in Tuzla started to search for new shipbuilding areas. In order to meet the national and international demands in the coming period, creating these new investment areas is very important in terms of not only the added-value but also the employment opportunities it will create. The Shipbuilding Industry Special Expert Commission Report indicates that the cost of labor within the Main Entry Costs for 10000 DWT Chemical Tank Ship is around 20% of the total costs. Creating and developing new shipbuilding zones for the added value and employment opportunities it creates is included in development plans and reports (Fig.3).

Therefore, in the SPI Development Plan IX (2007–2013) Shipbuilding Industry Special Expert Commission Report (2006), "New Shipbuilding Areas and Places Demanded by Entrepreneurs" are specified. Among them, the demands analyzed and approved for Yalova are as follows;

"Shipbuilding Demands in Yalova:

- 1. Sefine Shipbuilding Co. Inc..; It is targeted to employ 750 workers and construct maximum 6,000 DWT ships.
- 2. Yalova Altınova Shipbuilding Entrepreneurs Corporation; It is targeted to employ around 4,000 workers in the shipbuilding to be established in the region by the firm composed of 40 persons/firms.
- 3. Gemak Shipbuilding Industry and Trading S.A.; It is planned within the scope of the project to employ 1000 workers and the yard to have maximum capacity to build 75,000 DWT.
- 4. Bayrak Shipbuilding Co. Inc..; It is planned within the scope of the project to employ 100 workers and the yard to have maximum capacity to build 15,000 DWT.
- 5. Boğaziçi Shipbuilding Co. Inc..; It is planned within the scope of the project to employ 1500 workers and the yard to have maximum capacity to build 50,000 DWT, the annual capacity to be 250.000 DWT/year, maintenance capacity to be 80,000 DWT, annual maintenance capacity to be 2.500.000 DWT/year.
- 6. Kaptan Marine Construction; Shipbuilding between 5,000- 100,000 DWT is targeted."

These demands imply an investment which is of capacity to employ around 8000 workers.

2.2.1 Istanbul Metropolitan Plan and Shipbuilding Zones

The 1/100,000 scaled Istanbul Metropolitan Plan was approved on 15.06.2009. It is necessary to consider the developments with the metropolitan plan and changed legal regulations. After several regulations such as the 5216 Metropolitan Municipalities Law, 5393 Municipality Law and 5302 Special Provincial Administrations Law, Istanbul's city boundaries and Istanbul municipal boundaries are overlapped. Although this situation offers opportunities to the Istanbul Municipal Administration to control urban development dynamics, the possibilities to evaluate the city within its region are still limited. The lack of regional development and regional planning and the administrative approach which handles all investments at the city level are the main factors behind this situation.

Shipbuilding areas appear under the heading of industrial areas in the Istanbul Metropolitan Plan Report.

The item 7.4.5 of the report is about shipbuilding areas. The report states the following about Istanbul shipbuilding areas;

"Shipbuilding in Istanbul are composed of three main groups; private sector shipbuilding (The Shipbuilding Zone in Tuzla-Aydınlı Cove), public sector shipbuilding (Haliç and Camialtı Shipbuilding) and military shipbuilding (in Pendik). In the shipbuilding area in Tuzla which does not have the possibility to expand, does not have adequate infrastructure and causes environmental pollution; construction, modification and maintenance of transport and passenger ships, and yachts will be performed. Shipbuilding activities within this area will be rendered healthier and the volume will be reduced in the short and medium term, and these activities will be restructured in the long term by partially altering the function of the area. In the shipbuilding development area in Pendik-Güzelyalı located in the western side of the Tuzla Shipbuilding Zone and illustrated with the symbol "TG" in the plan, the production of only yachts will be performed and social and cultural facilities will exist. The Haliç (Golden Horn) Shipbuilding Zone (Taşkızak, Aynalıkavak, Camialtı and Haliç Shipbuilding) which has historical and architectural value will partially maintain its shipbuilding function through the maintenance and modernization of city line ferries and IDO (Istanbul Seabuses and Fast Ferries Inc) ferries; in addition, it will serve the function of a touristic museum in which shipbuilding techniques from past to present are taught and exhibited." [İBB, 2009]

It is understood from the plan that Tuzla, which is the only private sector shipbuilding area in Istanbul, will be rehabilitated, its volume will be reduced in the short and medium term, and its function will be altered in the long term. The Metropolitan Plan implies that the Pendik area, which once specified as the shipbuilding development area, will be used only for the construction of yachts. However, ship orders that Turkey receive are concentrated on ships that transport burden and chemicals.

The Istanbul Metropolitan Plan covers a total area of 545.300 ha, and a part of only 190 ha of this total area is designated for shipbuilding. These numbers are the indicator of the fact that the shipbuilding areas in Istanbul operate in inadequate spatial conditions.

When considered in this respect, the decision of the Istanbul Metropolitan Plan on shipbuilding areas is as follows;

- Creating areas for reinforcement services and cultural facilities in Haliç, Taşkızak and Camialtı shipbuilding.
- Rehabilitating the shipbuilding area in Tuzla.
- Forming the recommended shipbuilding development area in the Pendik-Güzelyalı District.

After these decisions, private firms operating in shipbuilding sector started to search for new shipbuilding areas in neighboring cities which have strong interactions with the Istanbul Metropolitan Area. Shores of Yalova, which is a city located in the southern part of Istanbul and was once a district of Istanbul, started to become the new investment sites for shipbuilding firms. This situation has created a dispute between residents of shores of Yalova and investors who are in search for a second shipbuilding area within Istanbul's area of influence.

2.2.2 Yalova Master Plan and Shipbuilding Zones

In line with the directive principles set by the Undersecretariat for Shipbuilding Sector and Maritime Affairs and in line with the investment principles set by the Five-Year Development Plan IX; establishment of shipbuilding investments in Yalova is projected in the settlement decisions of the 1/25.000 scaled Yalova Master Plan.

In the 1/25.000 scaled Master Plan; in line with the shipbuilding activities projected in the Five-Year Development Plan IX (2007–2013), approximately 4500 meters of shoreline within the boundaries of the city of Yalova is designated for shipbuilding sector. In addition to shipbuilding zone the plan also offered a special landfill zone on the seashore to create sufficient place for shipbuilding related services.

It is seen that the area between the sea and the Karamürsel – Yalova Highway is designated for the function of "Shipbuilding Area", and the two sides of the highway are designated for "KSA-Urban Service Area".

When the plan is considered as a whole, it is observed that the eastern part of the plan (the east of Yalova city centre) is designated mostly for industry, urban service area, development housing area, shipbuilding, airport, dock; and the western part of the plan (the west of Yalova city centre) is designated mostly for tourism and tourism + housing. It was observed that the assessments done within this context were documented by the Environmental Impact Assessment Positive Report.

Land reclamation works for shipbuilding activities have been approved by the Ministry of Public Works and Settlement. The 1/25.000 scaled Master Plan has been approved by the City Council Decision after assessments through the relevant investor and ministry opinions.

This region is an attractive region for investors due to the facts that the government grants investment allowances and tax exemptions for shipbuilding works in this region, that the Marmara Region has skilled labor power and specializations on ship construction, and that several special expert groups exist in the region.

The Shipbuilding Industry Special Expert Commission Report particularly indicated that, in terms of safe and efficient working conditions Tuzla Ship Construction Areas located in the Istanbul Metropolitan Area is seriously inadequate.

The demand for the sector's output mainly comes from abroad. It is observed that, due to the region's skilled labor potential based on expertise and the suitability of the sea shore, the shipbuilding investment decisions which will provide employment to the region are in conformity with macro plan decisions.

The Tavşanlı Municipal Council's decision Nr. 2005/22 and dated 01.07.2005 reads as follows for the 4500-m coastline; "our municipality has decided by the majority of votes that the area in which the properties numbered … are located shall be rendered a non-housing area and the municipal plan shall be changed as a yacht and shipbuilding area …". With this decision, investments for around 36 shipbuilding started in the region. As can be seen in the decision of the municipality, the coastal area which was once designated for

housing was rendered as a shipbuilding area. This amendment was taken to court by the local people and non governmental organizations. Arguments of those who object to the amendment are centered on several points;

- High number of workers will come to the region after the establishment of shipbuilding areas and the local social structure will change accordingly,
- The coastal part which is used for second-houses will no longer be used for this purpose,
- The local people's relationship with the sea will end,
- Shipbuilding firms will spread into other areas,
- Other industrial activities will settle in the region which will be an inconvenient case for Yalova which is located in a first-degree seismic zone.

3 LEGAL REGULATIONS IN TURKEY RELATED TO COAST USE AND THE SHIPBUILDING SECTOR

Within the framework of decisions on the definition and use of shores in Turkey, the following comments can be made about the Yalova Shipbuilding Zone.

Different courts understood coast in different ways. While the 7th High Court made the decision that "Coast is a public good of social-character", the 4th High Court decided that "Coast is an economic resource".

While determining how the society uses (mode of use) and realizes (mode of realization) this resource, the factors that should be taken into consideration are the connection of the coast with the built-up area, its position, the character of the infrastructure needed to realize it, its accessibility, its geometry, and the ecological character of the environment. This assessment should be based on the contemporary planning approach and be done through Ecological, Social and Economic parameters in line with the Sustainable Planning approach.

In the Coast Law Nr. 3621 and dated 4.4.1990, The "Aim" part in the first article is as follows:

Aim:

Article 1 - The purpose of this regulation is to set the procedures for the settlement of shoreline in seas, natural and artificial lakes, and streams, for the use and protection of the shores and to set planning and implementation procedures for lands acquired by filling and saving, and for the coast-lines that are the extensions of the seas and the streams.

The scope defined in the second article is as follows;

Scope

Article 2 - This regulation covers the seas, natural and artificial lakes, and streams and shorelines, opportunities and provisions of using these facilities for public-interest, the procedures for planning and construction in the coasts and shores, acquisition and use of land by filling and reclamation, the procedures which define the establishment, powers and duties, working principles of the Shoreline Adjustment Commission and the explanatory notes for enforcement of Law.

As is seen, the coast law includes terms of protection and use for the public interest in the areas defined as coast.

In addition, the law states that structures and facilities that can not be constructed elsewhere due to the characteristics of the activity such as shipbuilding, workshop for separating ship apart, water products production and raring facilities, yacht port, shelter fishermen and yacht docks can be constructed.

It becomes evident after assessing the situation about the shipbuilding areas in Yalova with respect to the regulations about the definition and use of coast that important issues are;

- 1. The shipbuilding area is supposed to satisfy the demands related not only to ship construction but also to ship maintenance and repair,
- 2. Shipbuilding do not create an intense traffic burden for the environment it is located in as Container Harbors do, and therefore, the function of a shipbuilding should not be confused with the function of an harbor,

- 3. When selecting location for shipbuilding, it is needed to prefer locations where ship traffic is intense and skilled labor exists by considering the possibility of need for repair,
- 4. Moreover, due to the location of the new shipbuilding area, it requires security organizations such as marine fire department, and therefore, it should be linked with the shipbuilding in Tuzla and Gölcük,

In this respect, designating the sea side of the shipbuilding zone as shipbuilding reclamation area conforms to city planning principles when considered according to macro plan principles and the characteristics of the region. There exist several main approaches and principles used in development of urban areas.

The idea that growth and development of a city is dependent on several principles is discussed in the planning literature. Some of these principles which are included in the public development planning law require plans to be consistent with and linked to each other. This can be briefly explained with the principle; 'Integrity should be established between the micro and macro plans for the area that is planned to be developed and the structure of long-term plans' (principle of consistency between plans).

It is observed that the shipbuilding area seen in the 1/25.000 scaled Yalova Master Plan has been developed as part of the Five-Year Development Plan IX and the Shipbuilding Industry Special Expert Report prepared by macro scale SPI and ratified by Turkish Grand National Assembly.

In order for the shipbuilding sector to maintain its functions such as training, maintenance, repair and construction; by considering the measures related to the shipbuilding sector taken in the 1969 Program, the area was designated as the "Private Sector Ship Industry Area" by the decision of Council of Ministers Nr. 6/12421 and dated 22.9.1969; with the determination of the Aydınlı Harbor near Tuzla Istanbul as the shipbuilding industry area for the private sector. Since that year, the Pendik District has been concentrated on shipbuilding sector and its supplier industry.

However, since the designated area is not adequate in terms of changed demands and conditions; demands for the maintenance and repair of the coast for shipbuilding and naval vessels, or in other words, demands for the economic use of the coast have increased.

It is known that plots have been classified as shipbuilding area, boat yard and mounting area in the construction plan prepared for Tuzla. In the Pendik District, areas for vessels' maintenance, installation and repair facilities are limited. New areas are highly needed additional to the current shipbuilding areas operating with excess capacity due to increased demand.

For the rapidly developing maritime sector, in order for the private sector which is rapidly advancing and increasing capacity to satisfy the production demand coming from abroad and to realize increasing maritime investments in rational environments, shipbuilding activities are not included but only an area for the Istanbul Harbor is designated in the Five-Year Development Plan, the Shipbuilding Industry Special Expert Commission Report and the 1/100 000 scaled Istanbul Metropolitan Plan

Planning works related to ship construction, on the other hand, are observed mostly in macro scale 1/25.000 scaled plans for Sakarya, Zonguldak (Ereğli-Alaplı) and Yalova.

Geographical closeness of technical infrastructure, railways and highways necessary for the maritime sector, easy accessibility to energy, appropriateness of the sea in terms of its harbor and berthing, developed industry and supplier industry related to the maritime sector, and the district's status as the center of maritime education of the country indicate the fact that the region strongly supports this sector.

Since the investments planned in the city of Yalova are in conformity with the maritime sector and since this potential and labor force is very close to the skilled labor in the metropolitan area which is at one-hour distance, this proposed area is open to easy development.

When assessed through the macro plan principles, presence of qualified labor in the region and the current industrial positioning, it is concluded that the area designated for shipbuilding function by the 1/25.000 scaled Yalova Master Plan based on the SPI decisions is a very suitable area for large-scale shipbuilding, maintenance and repair.

4 CONCLUSION

- In the vision of the Istanbul 1/100.000 scaled Metropolitan Plan for 2023, while a transition to an economy established upon trade and services based on science and technology is projected, no assessment exists on industrial infrastructure.
- Functional changes are projected for the near future about Istanbul shipbuilding areas.
- However, there is no decision on how and under what conditions this transformation will be actualized.
- Private sector operating in the shipbuilding industry started to search for new areas in conformity with the national decisions in the region along with the Tuzla Shipbuilding Area which fails to meet the demand.
- Within this context, the coastal part of the city of Yalova was selected for shipbuilding investments.
- In the Yalova 1/25.000 scaled Master Plan, 4.5 km sea front was designated as shipbuilding area. New discussions arose after the designation of these areas as shipbuilding areas which were once designated for housing.
- Controversies between local administrations, investors and NGOs were taken to court.
- The decisions that court will make will be highly determining in terms of increasing the country's competitiveness and utilizing the added-value to be created for national and regional economic development.
- However, in the planning process in which community involvement and negotiation processes are inadequately functioning; it is apparent that these discussions will not yield desired results and there exists a need for a sustainable metropolitan strategy and an innovative planning approach in order to increase the country's competitive capacity.

New Communication Tools and eParticipation: Social Media in Urban Planning

Stefan Höffken, Chris Haller

(Dipl.-Ing. Stefan Höffken, s.hoeffken@rhrk.uni-kl.de , TU Kaiserslautern, Lehrgebiet cpe, Pfaffenbergstrasse 95, 67663 Kaiserslautern, http://cpe.arubi.uni-kl.de)
(Dipl.-Ing. Chris Haller, challer@urbaninteractivestudio.com, Principal at Urban Interactive Studio LLC, Englewood, CO, http://urbaninteractivestudio.com)

1 ABSTRACT

The Internet and new Web2.0 tools are changing the way we communicate in an unprecedented way. Weblogs, Microblogs (like Twitter), and social media in general enable worldwide, real-time, multimedia communication with low barriers to entry. But in what ways are urban planners taking advantage of these new communication channels? This paper discusses these new opportunities as well as the barriers they present, and it makes recommendations for using social media in the urban planning processes.

It begins with a theoretical overview about participation in urban planning, eParticipation, and social media. In its second part, the paper analyses six real-world projects to study their social media strategies. Those examples will be used to identify best practices and reflect on the usefulness and effectiveness of various social media channels in the context of the planning projects to which they are applied.

2 THEORETICAL OVERVIEW

2.1 The Internet and Changes in communication

Technological development over the last decades has radically changed our communication patterns and led to the creation of what has been called the Network Society (CASTELLS 2000a). The Internet and the rise of information and communications technologies (ICT) are the basis for a new technological paradigm which has caused a fundamental shift in our society toward “The Internet Galaxy” (CASTELLS 2005). “Mass communication used to be predominantly one-directional. However, with the diffusion of the Internet a new form of communication has emerged, characterized by the capacity of sending messages from many to many, in real-time - or chosen time, and with the possibility of using point-to-point communication, narrowcasting or broadcasting, depending on the purpose and characteristics of the intended communication practice” (CASTELLS 2009, 55).

With the rise of the Internet in general and more recently with the emergence of Web2.0 - web applications that facilitate interactive information sharing, interoperability, user-centered design, and collaboration on the World Wide Web - the costs of global publishing have collapsed (SHIRKY 2008, p. 9). Easy-to-use communication and publishing technologies have caused a shift from predominantly one-to-many to many-to-many communication, challenging the dominance and even the existence of “old” media like television, newspapers, and radio. Today, the Internet provides a low-threshold method of communciation between nearly everybody, worldwide. Whereas real-world communication is limited by distance and time, online tools enable many forms of instant, global, and nearly permanent communication, so that ommuncations are stored online and easily acessible over the long-term by a broader audience (SHIRKY 2008, 87 ff.). “We are living in the middle of a remarkable increase in our ability to share, to cooperate with one another, and to take collective action, all outside the framework of traditional institutions and organizations” (SHIRKY 2008, 20 f.). Never before have people enjoyed the ability to collaboratively collect, analyze, and publish information on such a mass scale.

But, “the invention of a tool doesn't create change; it has to have been around long enough that most of society is using it. It´s when a technology becomes normal, than ubiquitous, and finally so pervasive as to be invisible, that the really profound changes happen, and so for young people today, our social tools have passed normal and are heading to ubiquitous, and invisible is coming” (SHIRKY 2008, 105).

Although the Internet at first was mostly used as an information medium, our developed societies now embrace it as a participatory medium through which to connect, communicate, discuss, and participate in nearly every realm of daily life, from home, to work, to politics. The Internet of today has become “one of the most powerful organizing tools in history” (Bittle et al. 2009, 1).

3 EPARTICIPATION AND WEB2.0 IN URBAN PLANNING

3.1 Web2.0 and social media

The term Web2.0 essentially reflects the current state of the Internet as a truly interactive medium. It describes the shift from top-down, one-way communication to a vastly more participatory medium. Through this 2.0 version of the Internet, users take part in the production of online content: They publish their thoughts on blogs, upload and share videos and photos, and connect with friends using social networks like Facebook, all of which are typically easy to access and free to use. These many-to-many communication tools are commonly referred to as social media, "a group of Internet-based applications that build on the ideological and technological foundations of Web 2.0, and that allow the creation and exchange of user-generated content" (KAPLAN 2010).

Web2.0 has kicked off the digital decade (LOBO 2009) and today a vast majority of people use the Internet as a part of their everyday life. In the United States, 74% of citizens use the Internet (Pew Research Center 2010); in Germany, nearly 70% are regular users (Initiative D21 2009, 10). Furthermore, statistics reveal a penetration of nearly all social groups and ages. Today, the Internet is a communication medium used by the majority of citizens in western societies.

3.2 eParticipation

Recently, our field became embroiled in a heated discussion as to whether the Internet could be used to conduct meaningful public participation. Today, we have mostly moved past this discussion, as many successful participatory projects online have been conducted and online engagement approaches have become a valuable tool. Though it's true that varying degrees of computer skills still require face-to-face alternatives, eParticipation is here to stay. In fact, the amendment in 2004 of the German Town and Country Planning Code (§3 in combination with §4a BauGB) has only emphasized the importance of digital technologies in public participation processes (STREICH 2005, 154).

eParticipation refers to the participation of citizens and stakeholders in decision-making through the instrument of information and communication technologies, mainly in government and governance. "eParticipation describes efforts to broaden and deepen political participation by enabling citizens to connect with one another, and with their elected representatives and governments, using Information and Communication Technologies (ICT). Thus, eParticipation can satisfy both the citizens' need for being both heard and involved in the democratic process, and governments' need to devise new mechanisms for promoting and encouraging public consultation" (Tambouris 2007, 5).

eParticipation offers new and effective ways to present, discuss, and visualize ideas and proposals. The digital infrastructure allows planners to easily save and aggregate datasets for ex-post analysis (statistics about activity, collaboration, interaction, group-processes, etc.) and to publish the results.

3.2.1 Different levels of interaction

To categorize and analyze the different categories of interactivity, we will refer to the three different levels as defined by the OECD (OECD 2001):

- Information: A one-way relation in which information is produced and delivered
- Consultation: A two-way relation in which feedback from the users to the project is provided
- Participation: A relation or partnership that allows diverse discussion to shape plans and develop new concepts

The pressing question today is how are planners leveraging the power of social media for urban planning processes? Because urban planning has always been based on the gathering and exchange of information and—as a democratic process—on communication between different stakeholders, a change in the method of communication has a significant impact on decision-making throughout the process.

3.3 Popular Social Media Channels

3.3.1 Twitter

Twitter (www.twitter.com) is a microblogging-service that allows users to publish short messages—140 characters or fewer. It launched in 2006 as a simple way publish and share SMS (short text messages) via the Internet (SARNO 2009). Users have to sign up for an account to publish updates or "tweets," which are publicly accessible the instant they are sent. Updates can be sent via phone, Web interface, or a variety of third party applications, including other Web applications. Others can subscribe to (that is, "follow") the stream and answer (via @useraccount) or forward interesting messages (a so called retweet, or RT) to their followers. Limited by the number of characters, messages typically contain snippets of information and a link to other URLs for more information. Group discussions reference a shared hashtag—each user includes the agreed upon hashtag (#hashtag) in their posts and others can simply follow all posts that contain this piece of information. This naming convention allows groups to easily interact without much coordination, for example at conferences or around elections. All that is required is an agreement on a shared hashtag. Because updates are publicly accessible and the method of networking with others by simply following, responding, and interacting with them openly is a simple one, Twitter has become popular as a simple tool for projects to interact with their respective target audience.

Other similar providers exist, for example the open-source service identi.ca, which supports the OpenMicroBlogging-standard (http://identi.ca/), but none has reached Twitter's popularity.

3.3.2 Facebook

Facebook (www.facebook.com) is a Social Network Service (SNS) that allows friends to communicate and share information, images, and videos. Every user creates a profile, with his or her name, age, interests, and other personal information and then posts status updates or images about their life. By default, profiles and updates are only available to friends and not to the general public. Users add friends to their account by searching for their names or through others they are already friends with (their Social Graph). Once the other person accepts the virtual friendship, both users have access to each other's information and both of their social graphs or networks have grown. Friends can communicate via messages, status updates (visible on their "wall," a real-time activity-stream), and chat. They can also share photos and post events. It´s easy to use and free. Compared to Twitter, user information is typically closed and only accessible to friends, though

Every user has the option of creating or joining public groups. Normal groups allow users who are not friends to collaborate with others who share an interest in the same topic. Pages, or fan groups, are typically organized by one user and are used to represent an NGO, organization, or similar institution. Ordinary users demonstrate their support or interest by becoming "fans." Both types of groups allow group administrators to send messages to all of their members and to use other organizing features. Most groups are member-focused, whereas the communication in fan groups is more one-directional (from organization to fan).

Other popular SNS are Myspace, LinkedIn.com, and Xing.com.

3.3.3 Flickr

Flickr is an image-sharing Web site, which today hosts more than 4 billion photos[1]. Flickr was developed to share personal photographs with others online (SHIRKY 2008) and can be described as an online community of photo enthusiasts. It is also used by bloggers to host images which they embed on their Web sites. Users sign up and create an account with some personal information that is accessible as a public profile to others (similar to Twitter). Uploaded photos can be organized with tags to enable easy searches by topic (e.g. subject, event) and can also be geo-referenced. This makes Flickr a powerful photo-collaboration tool. For example, images from the same event by various photographers can be accessed via a simple tag search. The same is now possible with maps, whereby Flickr allows users to browse pictures that have been taken in their neighborhood. Flickr offers a free account with limited data and an unrestricted pro-version.

Other popular photo-sharing Web sites include Photobucket.com, Picasa, and Panoramio.com.

[1] http://blog.flickr.net/en/2009/10/12/4000000000/

3.3.4 Youtube

Youtube is a video-sharing Web site where users can upload and share their own videos. The platform is open for everyone to watch or contribute videos. Users have to register in order to upload videos and create a personal profile (similar to Twitter and Flickr), a so-called channel. Youtube can be regarded as an online community, because user can pick favorite channels of subscribe to other users. The service allows users to upload unlimited videos and or to integrate videos to other Web sites (for example, their blogs or Twitter or Facebook accounts) through a piece of html code or via URL.

Other popular video-sharing services include Blip.tv, DailyMotion.com, Vimeo.com, and Brightcove.com.

3.3.5 Overview

All of the services outlined above have become quasi-standards in their particular niche. They share a set of commonalities, like free use, an easy learning curve, and the ability to comment on others' content.

	Twitter	**Facebook**	**Flickr**	**Youtube**
Learning Curve	Easy	Easy	Easy	Easy
Cost	Free	Free	Free (limited webspace)	Free
Ability to Comment	Anyone on their own page	Only Friends	Anyone	Anyone
Detail of Personal Profile	Low	High	Medium	Medium
Public Access to Profile	Yes	Limited	Yes	Yes
Level of Connectivity	High	High	Medium	Medium
Real-time Status Updates	Yes	Yes	No	No
Barriers to Registration	None	None	Yahoo-account needed; Cost for pro account	None

Fig. 2: Overview of the different Social Media Services used in the researched projects (own depiction).

4 EXAMPLES OF PLANNING PROJECTS LEVERAGING SOCIAL MEDIA

To analyze the use of the new social media channels in Urban Planning, we will take a closer look at six examples. We have selected these examples because we feel that they best exemplify today's use of social media in planning projects. We chose three top-down-initiated projects and three bottom-up projects to compare the differences. Because the sample is so small, the results are intended to give a general overview, rather than scientific results. This said, we do feel there's a need for more research in this realm, and we hope that our paper will in some small way inspire further discussion. To our knowledge, there have been no other attempts to analyze the role of social media in urban planning. There are, of course, a number of excellent examples of how to use dedicated online platforms for public participation. However, our paper will focus solely on the use of social media channels for public participation. It is not our intent to analyze the outcomes of eParticipation in urban planning in general.

To get a better sense of how and how effectively social media channels are used in each planning project, we analyzed a set of indicators that include the number of followers/fans/subscribers, the activity of the host (posts, video-uploads, photo-uploads, moderation of discussions), and the responses of participants (comments, video-uploads, photo-uploads, participation in discussions). The different levels of interactivity were classified into three categories: high, medium, and low. Interactivity is understood as the bi-directional communication between different project team and their participants.

4.1 Top-down examples:

In the following pages, we present three top-down initiated projects and then contrast these with a trio of bottom-up projects, all of them initiated by different groups or organizations.

4.1.1 GO TO 2040: Metropolitan Chicago's official comprehensive regional plan

Fig. 3: Screenshot of the main Web site of the GO TO 2040 project

GO TO 2040, the official comprehensive planning campaign for metropolitan Chicago, was launched in August 2009 by the Chicago Metropolitan Agency for Planning (CMAP) and makes extensive use of Social Media to support the planning process. The GO TO 2040 processes aims to "develop a preferred future scenario," which is "based on residents' feedback...and on quantitative analysis of...regional indicators." The preferred future scenario is used to develop strategies for the official comprehensive regional plan for metropolitan Chicago.

To get involve residents in the process and to attract them to the many workshops in the region, the project uses a variety of social media channels in addition to its main Web site. These channels include Blog, Twitter, Facebook, Flickr, and Youtube, all of which are linked from the campaign's Web site. According to Anne Holub from the CMAP, the biggest challenge "was acquiring new followers across social networking platforms" (HOLUB 2009).

	Twitter	Facebook	Flickr	Youtube	Weblog
Followers/Fans	661 followers, featured on 83 lists	277 Fans	36 contacts	5 subscribers	Not available
Project Activity	772 tweets, direct responses to followers	3 uploaded videos, 1 photo album	6 albums (135, 113, 41, 30, 25, 23 visits)	33 uploaded videos (up to 982 views)	Not available

Fig. 4: Overview of analysis of the grade of interactivity (own depiction).

4.1.2 East Baton Rouge Comprehensive Plan, futurebr.com

Fig. 5: Screenshot of the project's main Web site

The "FUTUREBR" Web site was launched in December 2009 to support the Comprehensive Planning process for East Baton Rouge (EBR), Louisiana, which replaces the old comprehensive plan. A project of the City of Baton Rouge and the Planning Commission of the City, it seeks "to shape future growth in the city and parish over the next 30 years. This project is based on an inclusive, parish-wide process to craft a new vision, policy framework, and implementation strategies that reflect the needs and aspirations of parish citizens. FUTUREBR will guide the physical development of the city and provide a framework within which

individuals, businesses and public officials can make decisions that are consistent with the community's vision for the future."

Participation is open to residents and organizations in the region, which can take part in online discussions or workshops. The project has a central Web site, a blog with project updates, and a social media presence on Twitter and Facebook. Furthermore, visitors can subscribe to newsletters and notifications via Email.

	Twitter	**Facebook**	**Blog**
Followers/Fans	18 Followers, featured on 1 list	247 group members	Not available

(Disclaimer: This project just got underway, and it is likely that these numbers will increase.) Fig. 6: Overview analysis of the grade of interactivty of the project FUTUREBR (own depiction)

4.1.3 PLANitulsa – planitulsa.org

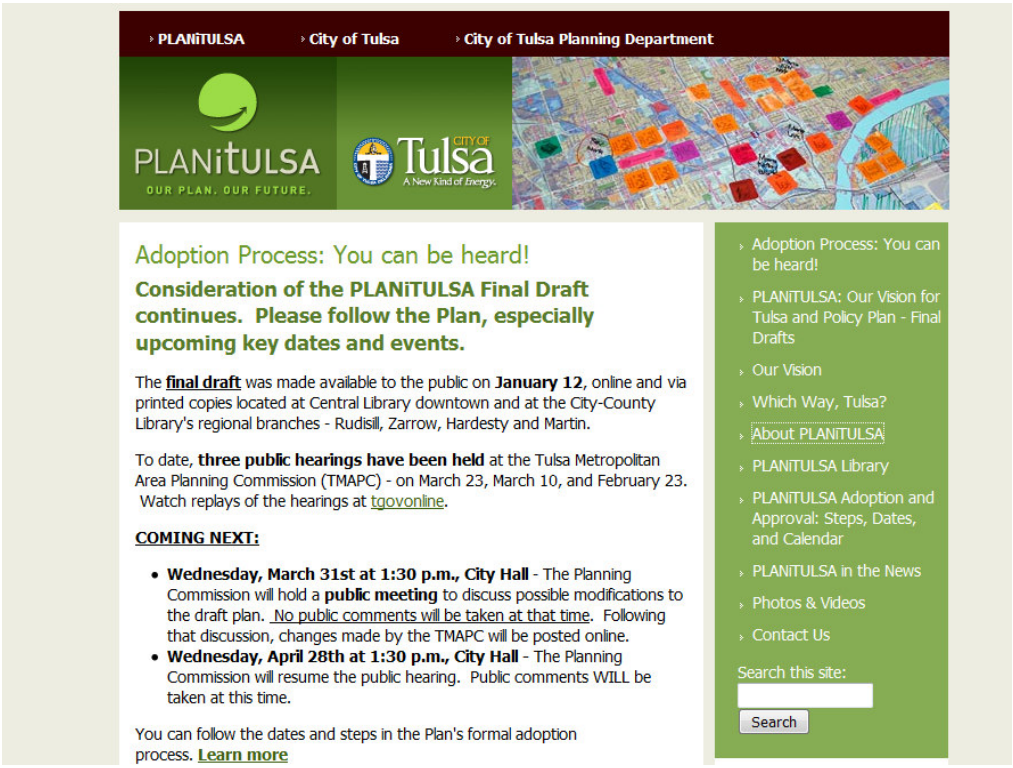

Fig. 7: Screenshot of the main Web site of PLANiTULSA.

PLANiTULSA is a project by the City of Tulsa, Oklahoma, to update the city´s Comprehensive Plan. The "Vision for Tulsa lays out concepts for how the City of Tulsa will look, function, and feel over the next 20-30 years. This vision is the guiding document for Tulsa's comprehensive plan update, PLANiTULSA, and

describes the kinds of places, economy, housing and transportation choices, parks, and open spaces that the city's policies should be designed to create." The planning department of Tulsa launched the Web site in April 2008, hoping to involve residents in the process through the Web and public workshops. Social media channels on Twitter, Facebook, and LinkedIn were used to engage and inform residents.

	Twitter	Facebook	LinkedIn
Followers/Fans	2100 followers (But this is the city's account, not the project's)	923 fans	107 members

4.2 Bottom-up examples:

4.2.1 Megaspree

Fig. 7: Screenshot of the main Web site of the bottom-up movement Megaspree.

Megaspree is a bottom-up citizen initiative formed in 2009 when its founders were organizing a protest march against the Mediaspree project, a large waterfront real estate development in East Berlin, Germany. The movement criticized the lack of social infrastructure and public spaces, as well as the project's planned displacement of subculture and low-income residents. The biggest success of the citizen movement was a public petition for a referendum in 2008, which was initiated by Mediaspree-Versenken[2], during which more than 30,000 citizens of the district of Berlin Kreuzberg-Friedrichshain voted 87% against Mediaspree. The movement is probably one of the most successful citizen-activism projects in Berlin in recent years. The initiative used a number of social media channels to engage its supporters: blogs, Twitter, Myspace, and Facebook.

	Twitter	**Facebook**	**Blog**	**Myspace**
Followers/Fans	220 Followers	2892 fans	Not available	2312 friends
Project Activity	131 tweets, no interaction with followers	- 6 videos - 8 albums	30 posts in 9 months (from Jul. 2009 to Mar. 2010)	Blogposts, 3 videos
Responses	No @responses, no interaction with followers	A lot of comments on the wall	Few comments	A lot posts, but only few about the project

Summary of Interactivity	Low	Medium/High	Low	Low

Fig. 8: Overview analysis of the grade of interactivity at project Megaspree (own depiction)

4.2.2 Canal Connection, canalconnection.com

Fig. 9: Screenshot of the main Web site of the bottom-up movement Canal Connection.

[2] Translates to "Sink Mediaspree"

Canal Connection is an interesting example of a citizen-driven project in support of urban development. In Oklahoma, MAPS 3 is a tax-increase initiative to fund future development projects, started with recent MAPS initiative funding. The Canal Connection initiative aimed to add a canal extension and bridge to the proposed MAPS 3-funded convention center, to connect it to their neighborhood. “Bricktown is the face of Oklahoma City, and must be tied to future downtown development conveniently and safely.” The project is coordinated by the “Bricktown Association in cooperation with multiple groups” and has organizational support of three local associations. The Bricktown Association “operates as a voluntary association whose primary goal is to promote the businesses in and around Bricktown and the entertainment district as a whole.”

	Twitter	**Facebook**	**Blog**
Followers/Fans	199 Followers, featured on 13 lists	7665 fans (Not just project related – Bricktown Association)	Not available

Summary of Interactivity	Low	Medium	Low

Fig. 10: Overview analysis of the grade of interactivty at project Canal Connection (own depiction)

4.2.3 Chattanooga STAND, chattanoogastand.com

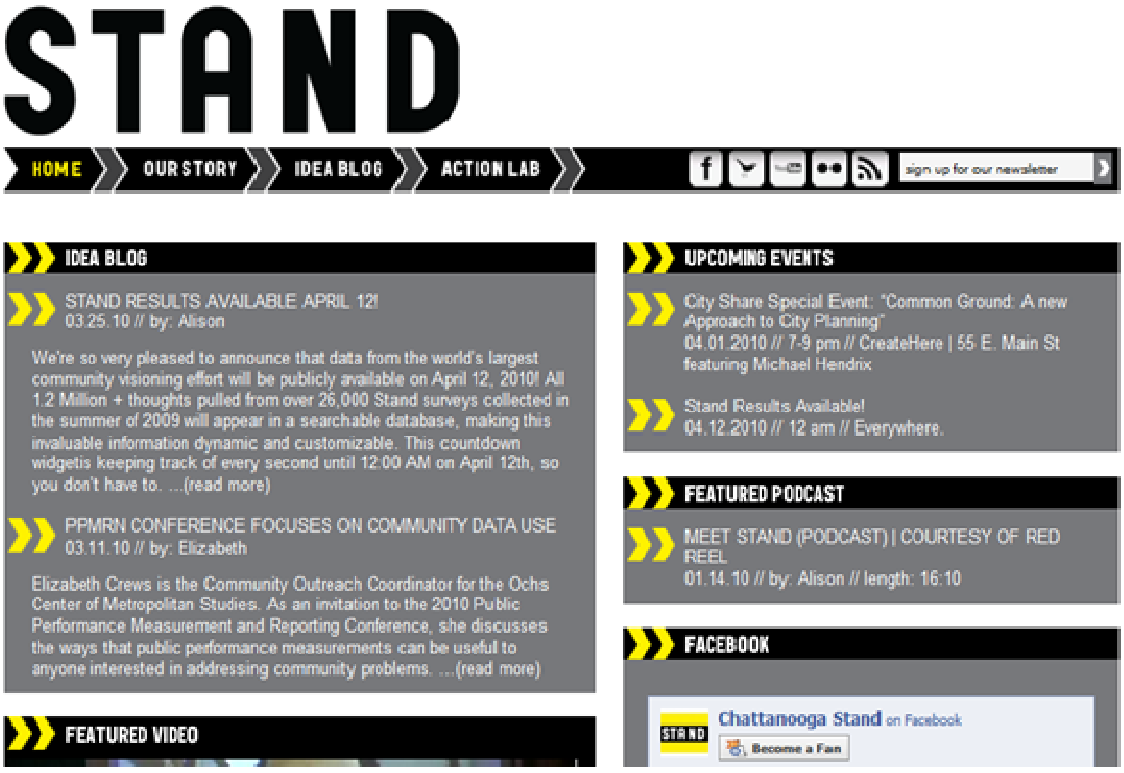

Fig. 11: Screenshot of the main Web site of the bottom-up project STAND

STAND is a community visioning effort "to engage community members to express their ideas for the future, organize around common purposes and translate vision into action." In 2008, different groups of citizens launched STAND "with a four-question survey and an initial goal of collecting responses from residents across the Chattanooga region," which ended up netting more than 26,000 responses. "The results of Stand's survey effort will be released to the public in early 2010. From there, STAND will encourage, enable and facilitate as many people in as many places as possible in creating their own changes to benefit not only those who filled out a survey, but the entire region—and like-minded cities everywhere."

5 CONCLUSIONS

Each of these projects deploys a different (though often overlapping) set of social media channels and each has its own way of utilizing those channels. Variations in the level of interaction (comments, votes, discussions, fan uploads) and the spread of the participants (number of fans, lists, subscribers, followers) are enormous, not just from project to project, but also between the different channels within each project. Twitter and Facebook are the most commonly used channels and most effective tools. The following diagram summarizes the different uses:

	Top-down	Bottom-up
Twitter	Most commonly used as a push medium for updates, but used effectively by Goto2040 to build a participant base.	Most commonly used as a push medium for updates. But more willingness to explore using them for more interaction and embracing of user-submitted content (e.g. using the API)
Facebook	Used for the same updates as on Twitter, but with added functionality like Events. Barely used as a platform for discussion.	Used for the same updates as on Twitter, but with added functionality like Events. Barely used as a platform for discussion. Pages of the bottom-up projects typically have higher numbers of fans indicating support for the project, than top-down-projects.
Flickr	A hosting service for photos, but not as a platform for interaction.	Only used in one case as a hosting service for photos.
Youtube	A hosting service for videos, but not as a platform for interaction.	Not used at all.
Weblogs	A push-medium for news. Few actually allow comments.	A push-medium for news. Few actually allow comments.

Fig. 13: Difference between use of Social Media in Top-down vs. Bottom-up projects.

Referring to 2.2.3, the different social tools are analyzed according to their levels of interaction and how they were used and implemented in the various projects.

	Information (provide updates, information)	Consultation (interact with project, provide feedback)	Participation (shape plans)
Twitter	6 projects	2 Projects	-
Facebook	6 Projects	5 Projects	-
Flickr	2 projects	-	-
Youtube	2 projects	-	-
Weblogs	6 projects	2 Projects	-

Fig. 14: Social Media at the different levels of interaction

5.1 Observations

On average, the greatest focus and highest activity and interaction in all of the aforementioned projects was seen on Facebook and Twitter. This is probably due to the high level of connectivity and the real-time aspect, as illustrated in Fig. 2. The examples show that Twitter is typically used as a push medium for project updates, probably because of its ease of use and the brevity of its messages. And, as Goto2040 and STAND demonstrate, a pro-active networking approach to using Twitter can generate support for projects in various ways. We've seen participants retweet event announcement, ask questions, and even provide positive feedback or quotes, like this one in Tulsa: "PLANiTULSA named best thing about 2009 by Urban Tulsa! http://bit.ly/58Ur7I." One thing we were missing is the use of a hashtag to exchange ideas around a project. Only PLANiTULSA had a few instances in which users provided event updates via hashtag (and these entirely user-created, inasmuch as the project didn't have a Twitter account). The effective use of hashtags could greatly improve the use of Twitter as a participatory medium.

Facebook offers more traditional ways of interaction and was used as a two-directional channel through which participants commented, voted, and started discussions. Such interactions were typically limited in

scope and intensity, though this is quite typical for Facebook. Indeed, fan pages and groups are often merely regarded as a way to show support or opposition for a given cause by joining, and not as a vehicle for sustained participation. This can also be seen by the higher numbers of fans for citizen-activism projects, compared to their official counterparts. Nonetheless, offering a fan page can be an effective means of gathering support, with the added benefit that event announcements and project updates can be easily broadcast to all fans. On the other side, Facebook is more personal in nature, which has implications for its use for planning projects. Though the group and fan pages on Facebook offer the greatest variety of tools for organizers (discussions, links, the ability to upload photos and videos, integration of other content), comments were often superficial and discussions were barely used. Additionally, Facebook users are often careful about protecting their privacy and typically share with their circle of friends rather than with the whole world, which limits the platform's use for general networking.

Overall, both Twitter and Facebook offer excellent ways to reach out to citizens and direct them to a project's Web site for deeper engagement or participation. Because Twitter and Facebook are somewhat limited both in the scope of activities they offer as well as the kinds of tools they offer, they tend to serve best as a kind of point-of-entry through which more vigorous and serious participation can be accessed. For their part, Goto2040 and STAND both demonstrated how providing URLs to surveys with compelling calls-to-action not only brought followers to their Web sites to participate but also, through retweeting, reached a far greater audience by bridging networks to connect with participants who might otherwise never have taken part.

The other channels didn´t attract discussion or high interactivity. Flickr and Youtube seem to be used mainly as hosting platforms, offering free Web space for videos and photos and providing easy ways to integrate them into the main Web site or to link to them. Even though all of these services provide the tools for feedback, they are rarely used by participants. None of the projects made use of a common tag to encourage citizens or participants to share photos in a common pool. We've seen this technique effectively used in other projects, and it's another low-barrier way to engage some of the more active citizens in a community.

Whether any of these channels can help projects to become more inclusive with diverse participation can't be answered by this analysis. Most likely, the answer would be some form of "it depends." We do want to point out, though, that the connections made by some of the projects that actively used Twitter seemed interesting. By using Twitter search tools to directly target users, projects seemed to interact with local decision-makers, journalists, bloggers, and other observers that all act as influencers within their own networks. Perhaps more than any other tool, Twitter enables this kind of open-networking and might ultimately lead to more inclusive participation by connecting different local networks. Interestingly, LinkedIn might work in a similar fashion, but was only used by one project.

To our surprise, more than one project provided a blog that did not allow visitors to comment. In a way then, these platforms had much in common with the news sections of Web sites as was typical in the 1990s, and technically we wouldn't consider those updates to be a blog. But this raises the question: How can organizers track, moderate, and answer comments or feedback from a large variety of channels? Rarely did the various projects seem to have an overarching strategy for how all these social media channels work together. We wonder how many of them first identified the overarching goals and objectives, and only then picked their social media channels and created an engagement plan that addresses these issues (more on this subject below). Ultimately, it's necessary to fine-tune the channels and how they interact to keep feedback manageable. For example, why offer a discussion board on Facebook if nobody is expected to use it? Or, perhaps worse, offer one that no staff member is assigned to monitor or post responses to? Within this logic, it might make sense to offer a "blog" that simply provides updates without allowing comments and to sync it to Twitter and Facebook. It keeps the overhead down and limited staff resources can be used to focus on more important channels or activities.

Overall, the most important channel for online communication in each of the projects we looked at seems to be the central Web site, which links and connects with all the other social media channels. The main Web site can be connected with other tools, to post and distribute information to all other channels in order to make the process of keeping users up-to-date as easy as possible. And though all the new social media channels we looked at are worthwhile and are increasingly important, traditional online communication tools like blogs and newsletter signups remain an important cornerstone for any outreach effort.

5.2 Recommendations

Though the further integration of social media may have become an increasingly mainstream priority, proven strategies for doing so are not easy to come by. It all comes down to this: Social media strategy must have a defined goal. Whether this is to educate citizens about the tradeoffs and alternatives of a planning project, to identify local connectors and network with them, or to collect feedback about different alternative scenarios, in order to be successful the outcomes must be defined and quantifiable. After the goal is defined, the timeframe and target audience of a social media campaign should become clearer. Will this be a short-term campaign, or something more permanent? And depending on the audience, various social media technologies should be weighed as to which is most appropriate in attaining the identified goal.

One thing that becomes obvious when taking a closer look at the various planning projects is that it's one thing to create project Web sites or Social Media accounts, but it's a totally different story to actually get people to visit them and get engaged. To avoid non-participation, we recommend creating an Engagement Plan[3], a document that to outline a project's strategy for getting an audience to participate well before its Web site and social media accounts are launched. The elements of an Engagement Plan should include:

Channels: Which complementary on- and offline channels will the project use to let people know about or contribute to the project? How will the project tie them together? How will the project keep them updated, facilitated, and responsive?

Activities: What will the project ask people to do on its site and elsewhere? Without a clear indication of what is expected, nobody will actually begin. For example, if a project wants its audience to use Flickr, perhaps it could offer a photo contest? What incentives can the project provide to reward participation?

Roles and responsibilities: Who is responsible for content creation, animation, promotion, outreach, tech support, and other functions? Is someone at the project prepared to provide the first comments, videos, etc. until such time as a community forms around the project?

Timeline: What needs to happen and when (including dependencies and periodic evaluation of success metrics)?

Use Policy: What principles should the project team keep in mind in order to define a consistent voice and approach for the project (SAMUEL 2008).

Before implementing a new engagement plan, addressing the maintenance of the campaign is critical. Leveraging the power of social media for a project requires a lot of detailed, time-consuming work.

6 OUTLOOK

With the widespread adoption of mobile devices and the mobile Internet, new services are emerging that bring social media directly into our neighborhoods. Smartphones like the iPhone provide a new platform for location-based-services and mobile participation processes, while becoming more widely used. Mobile applications amplify participation in a spatial and temporal dimension and will widen the range of possible uses for urban planning and design. Whether traveling in the metro or sitting in a coffee shop, participants not only can read or post updates but they will also be able to interact with the built environment and others around them in real-time. As an example, new location-aware social media applications like Foursquare and Gowalla are paving the way for online engagement around any given city. Both services offer a check-in system through which users share their current locations, interact with other users, and earn badges for visiting a certain number of places. Users who check in most frequently become the "mayor" of a location. And this is just the start of what will surely become the widespread adoption of location-aware services. Indeed, even as we prepared this article, Twitter opened its Geo-API and it is expected that Facebook will roll out similar features in the near future[4]. This offers two interesting angles for our planning professions:

- By aggregating user locations that will soon be widely available, planners will be able to analyze mobility and usage patterns of neighborhoods, identifying clusters and areas of decline.
- By working with services like Foursquare, Twitter, and others, planners will be able to create their own games and provide engaging channels for citizens to get engaged. The oft-hyped crowd-

[3] http://www.socialsignal.com/blog/alexandra-samuel/engagement-planning
[4] http://mashable.com/2009/12/25/foursquare-gowalla/

sourcing only works if there's a fun, entertaining side to collecting data or mapping neighborhoods. Location-aware games could provide a venue to get citizens involved early in the planning process.

Armed with new social media tools and access to information, citizen planners will soon join professionals in our search for the liveable cities of tomorrow.

To advance the use of social media in Urban Planning, exchanging ideas, experiences, and lessons learned is critical. Therefore, we invite you to provide your feedback and share your own experiences with us and others in the comments section at http://engagingcities.com/post/484625327/corpsocialmedia

New Prospects for Urban Planning Service Systems with Use of GIS Tools and New Data Sources Linked to Reference Databases

Jadwiga Brzuchowska

(Dr Jadwiga Brzuchowska, Wrocław University of Technology, Faculty of Architecture, ul. B.Prusa 53/55 Wrocław, jadwiga.brzuchowska@pwr.wroc.pl)

1 ABSTRACT

Spatial management at present has the opportunities to obtain support by information in unusual scale. Such prospects are open by using the tools of urban spatial information system and possibility of linking the reference data with new sources of information emerging in the development of e-administration. As the examples of establishing such a link, and of the variety of analysis made available consequently, two cases of processing data from thematic databases based on Wroclaw urban spatial information system are presented.

2 INTRODUCTION

Development of e-administration reveals chances, often unconsidered, of achievement of new dimension in analyses, planning and management of urban systems. They let us open ways of acquiring and processing of detailed information with spatial reference from the sources of data, which were inaccessible until now. If, as it often happens, the particular information concerns individuals (e.g. inhabitants, investors, clients, vehicles), their activities and registered events, but the database includes whole population or its significant representation, then it represents the ideal base for analyses and modelling of phenomena and processes, for construction of models of city or its subsystems. Research of human behavior can allow to adjust better for requirements of communities, but also it enable determination of spatial policy towards prevention of undesirable spontaneous processes.

One possible kind of the source of information are the existing formal registers (such as the records of inhabitants' accommodation, or records of economic activity), due to the mandatory recording of the different types of activity or of use of services of state or communal administration. These data include information of the registered events' addresses, which allow for allocation of its spatial reference, with proviso that the conformity with reference data is improved.

Furthermore, information may be acquired from electronic systems of services, emerging in process of development of e-administration, like the further presented system of recruitments to schools in Wrocław. The key factor is that data should be acquired by imposing the appropriate way of registering the information.

Efficiency of preparation of input data for analyses depends on conformity of address data model, on improvement of reference data, on making the addresses dictionaries available, and consistent adjustment of registers (or other thematic bases) to the created standards and dictionaries. In the context of the present state of address information incompatibility it is essential to apply the emergency mechanisms of adjustment of the incompatible data.

3 CREATION OF PREMISES FOR PLANNING OF SYSTEMS OF URBAN SERVICES ON EXAMPLES OF DEMOGRAPHIC ANALYSIS AND OF PROCESSING THE DATABASE OF SCHOOLS AND THEIR PUPILS IN WROCŁAW

For the presented examples of analysis the reference data (address database) modernized in the process of extension of Wrocław urban spatial information system (SIS) has been used, along with reports from two bases in the form of table including address information, namely: registers of inhabitants accommodation, and database of electronic system of recruitment in schools via the Internet.

Moreover, the analysis referred to the division to the urban units, which are used in monitoring and planning the development of the city, as well as to other thematic layers of SIS (e.g. landuse - current status and projected development, model of transportation network, characteristics of the cost of displacement).

Reports from the registers of inhabitants accommodation allowed for examination of demographic and spatial structures and of internal migrations of inhabitants of Wroclaw. The yearly examined data concerned the inhabitants of Wroclaw, domiciled in permanent or temporary residence in the time-span of the last decade, taking into account the age and gender structure, as well as the migration of residents, with

recognition of the age and gender distinction as above. The data were aggregated to address point.
Geocoding of information on place of residence and its change as well as examining the spatial relationships with other characteristics of the places (e.g. distance from the city center, type of residential area), provided new information on the demographic and spatial structure of population, trends and dynamics of migration processes within the city and beyond its borders.

Additional information was gained from the joint analysis of information about migrants person, which embraced the origin and destination place of migration characteristics, and migrations' length. Received information both provides characteristics of particular sites, and allow to define the quantitative indicators, which form the basis for the forecast elaboration.

The demographic analyses and forecasts are object of interest of the majority of the municipal authority's Departments, as a base for definition of needs for publics services (health, social care, education), and of requests for media (water, heating, gas, internet).

The size of the age groups population as forecast for the subsequent years, and the observed differences in their density in different areas, are essential for planning of the number, of the spatial distribution, and of the time-related changes of particular types of services.

Fig.1 and 2 illustrate the examples of such demographic analyses (Brzuchowska J. ,2009).

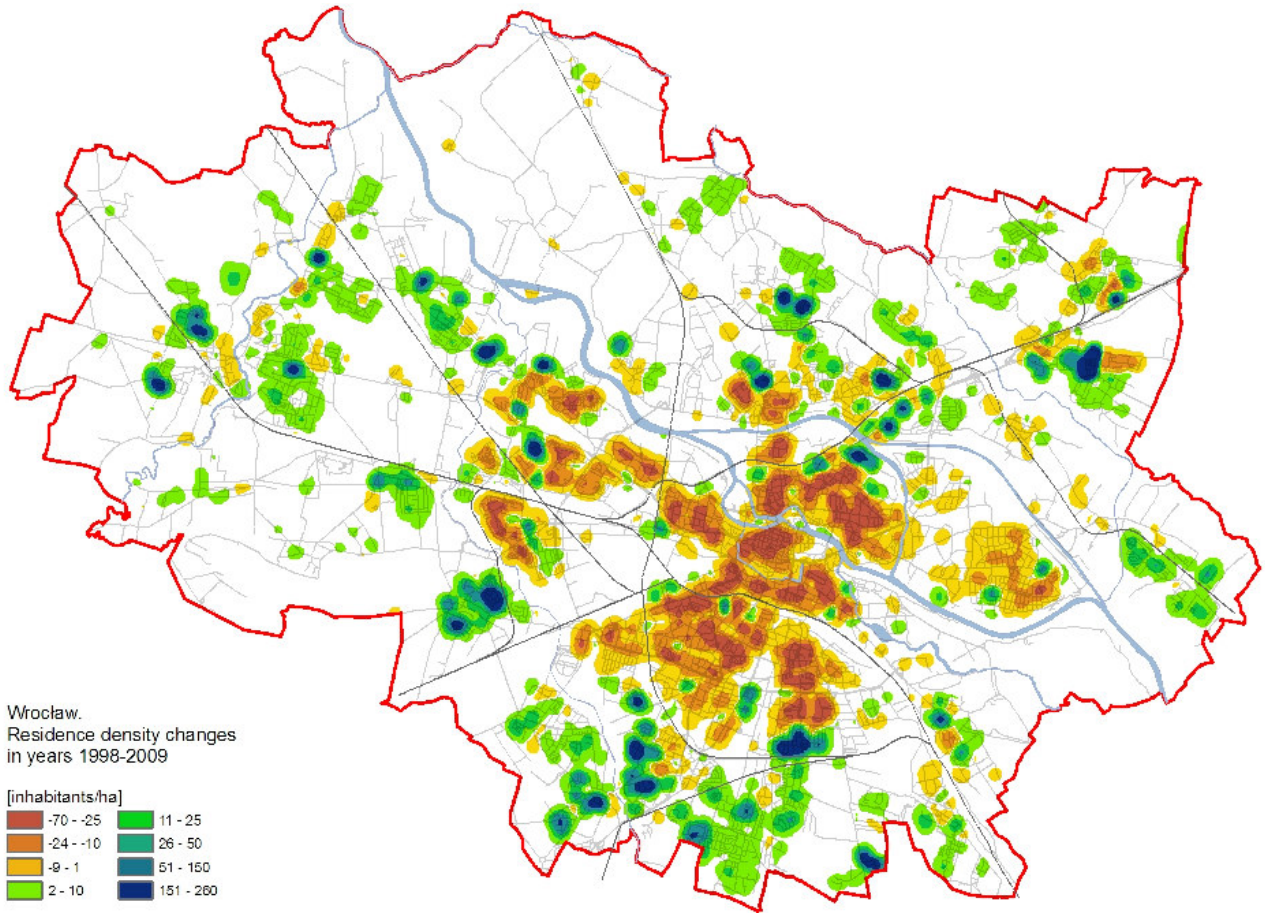

Fig. 1: Map of residence density changes in the area of Wrocław in the years 1998-2008, Elaborated on the basis of the permanent residence registers

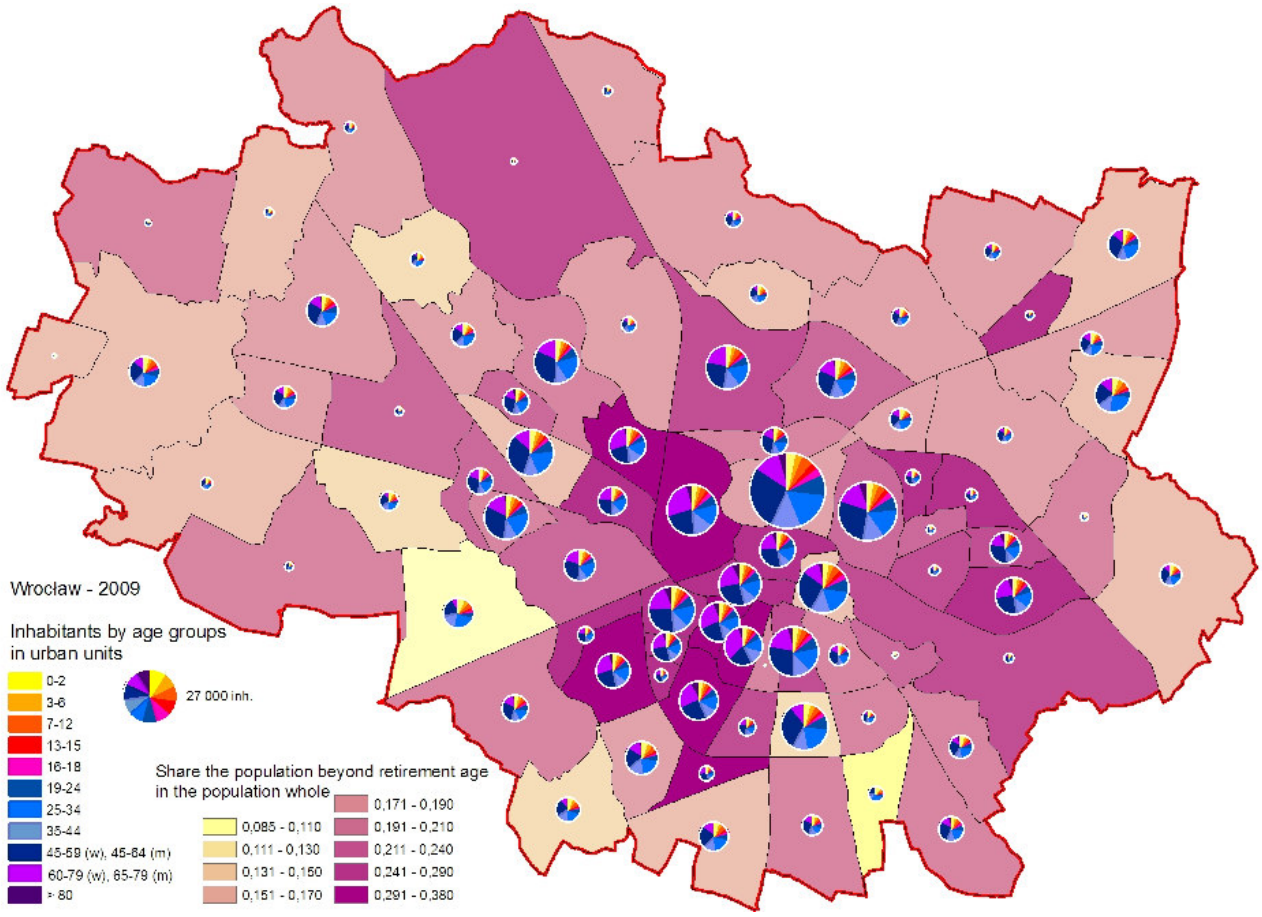

Fig. 2: Distribution of inhabitants of Wroclaw by age groups ratio in urban units. As at 31 December 2009. Elaborated on the basis of the permanent residence registers

A detailed framework for examining the deployment of children in relation to the location of different levels and categories of schools has been provided by the database of system of recruitments to schools, which embraced the places of residence of each school's students, referenced to the address point or, in case of the suburbs of Wrocław, to a village.

The good cooperation of the recruitment system with the Wrocław urban SIS data sets and tools is the result of several years of experience of users of the both systems, including their extensive application, and active cooperation in the modernization of the reference databases. Year by year the increase of the amount of the collected and processed information is noted, as well as the range of the analyses conducted. The above examples relate to the school year 2008/09.

Geocoding of objects was the starting point for conducting a series of visual and quantitative analyses including - among others – various images of the deployment of objects and their spatial relationships, the flow rate and the intensity of these phenomena, the study of diversification of the service indicators (spatial accessibility, distribution of commuting distances to the schools of different kinds and levels, the number of schools' attendants). Distributions of travel distances examined along with the deployment of citizens counted in relation to the school location, allow for the determination of the parameters for the simulation of home-education contacts. In this way, characteristics of both schools and zones of different type of residential area and inhabitants' socio-economic profile, were built.

Juxtaposition of data has allowed also for investigation of the compliance of school districts' ranges with areas of the allocation defined with assistance of GIS tools, and with the real spatial distribution of living places of each school's students.

The analysis provided the rationale for both planning a network of schools and the arguments for specific decisions concerning the maintenance or elimination of particular schools, or finding their substitute localization. The results' output allows also to identify the under-served areas.

Geocoding was used not only for planning and analyzing: in the recruitment process the evaluation of the place of residence of the child, and of its distance from the school of their choice, was considered.

The minuteness of the acquired information implies the search for new techniques of analysis and of the phenomena presentation. The examples of such attempts are to be found among the illustrations enclosed.

Figures 3 A and 3 C show, in various forms, where students of III LO (High School) school are recruited from. Figure 3 A and B present graphs of young people who commute to two high schools with different social profile. Fig 3 C and D, in the form of traditional cartograms, based on quantitative assessments, show areas with a population of greater degree of educational aspirations.

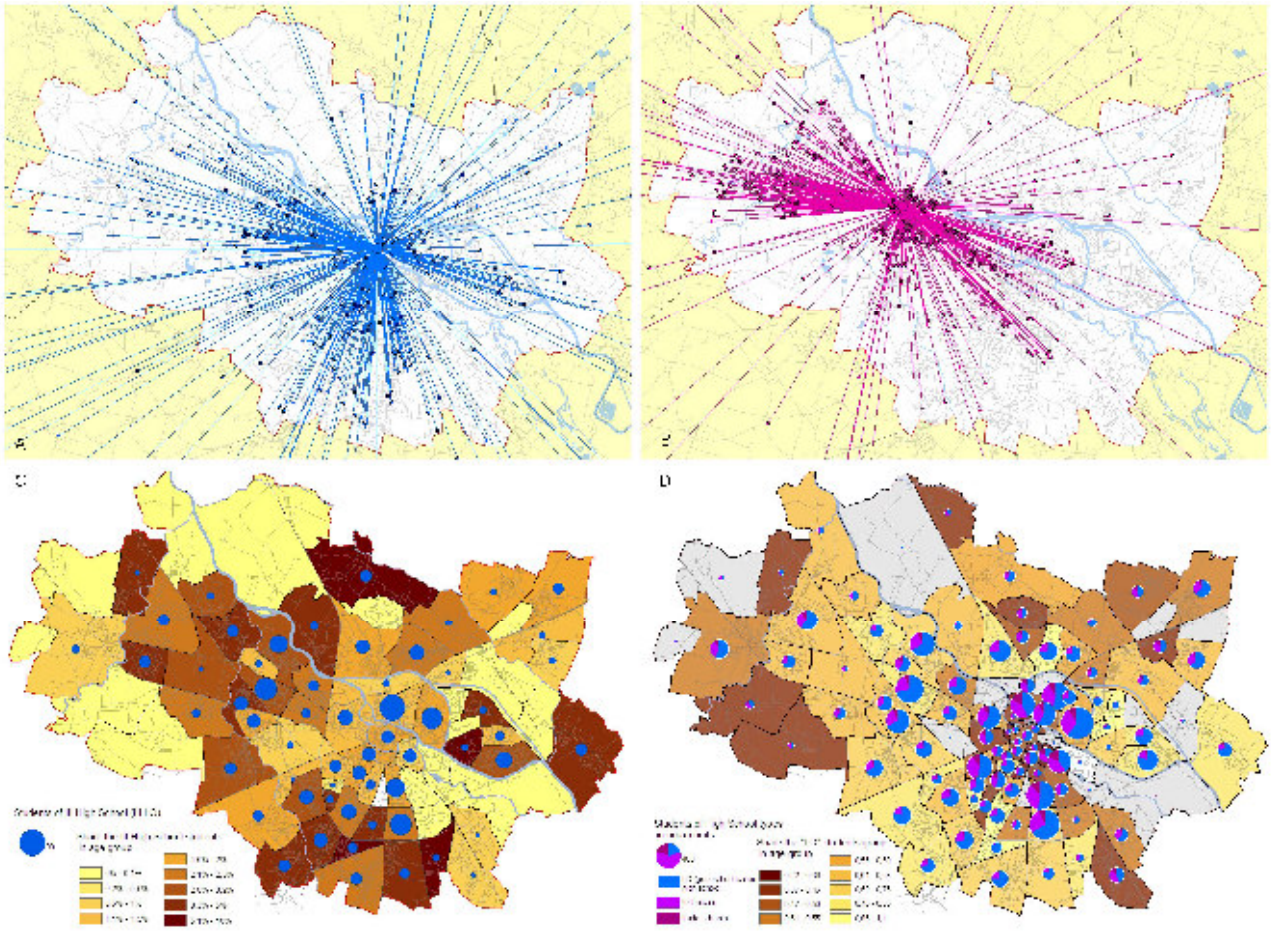

Fig. 3: Examples of analysis of the distribution of students: A) Graph of III High School students commuting to school B) Graph of VI High School students commuting to school C) Participation of III High School students in the age group (in the urban units) D) Participation of all high schools students in the age group

In the Figure 4 the spatial distribution of children commuting to different types of school is illustrated with use of a new version of trip-directional plans, matrix of displacements visualization method (Brzuchowska J., 2010)

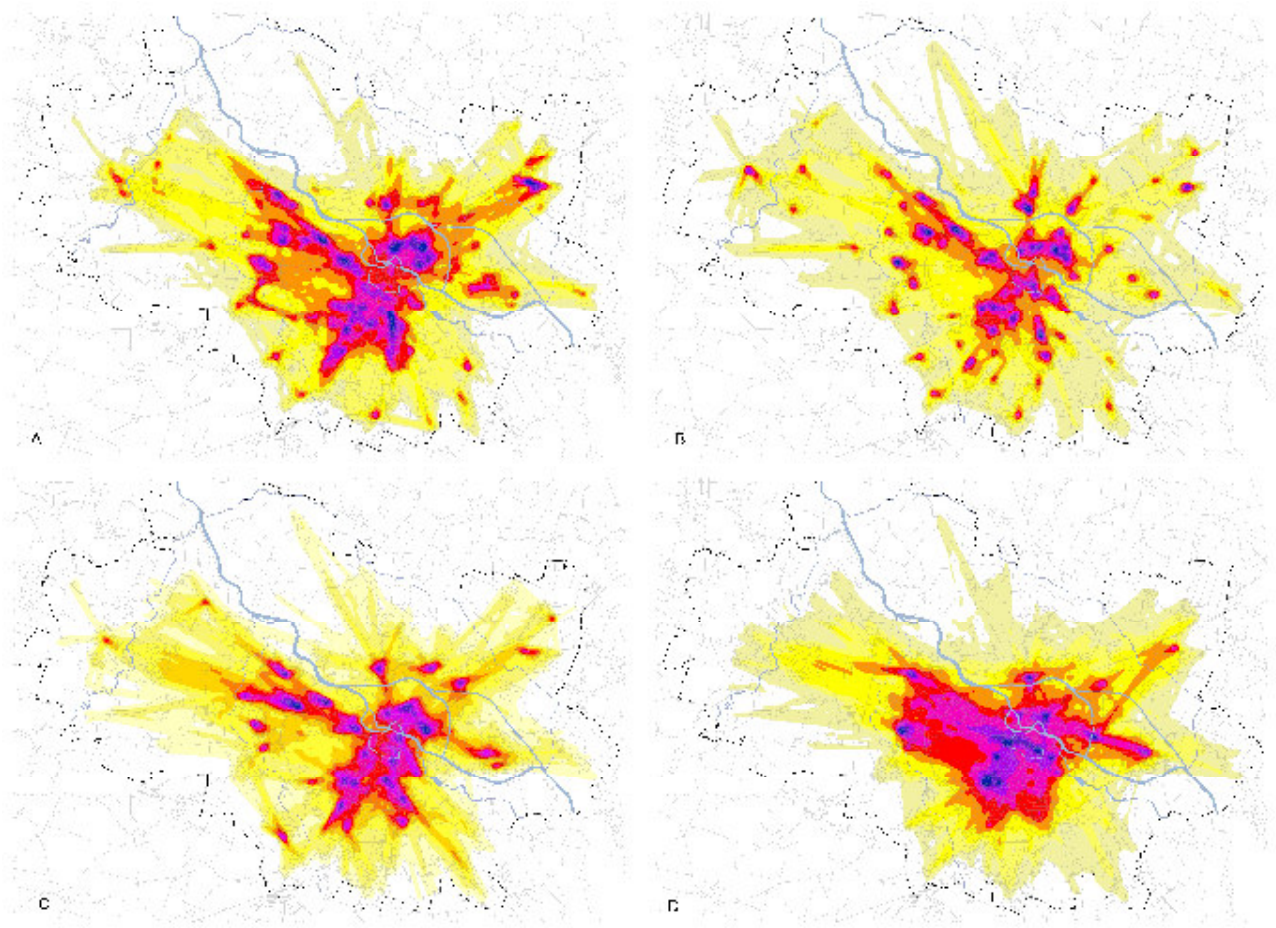

Fig. 4: Displacement density of children communiting to school of various level A) kindergarten B) primary school C) secondary school D) high school

4 CONCLUSION

Urban geoinformation systems are often used to record rather than for analysis of the information and for planning support. The new opportunities are a challenge for developers and users of geoinformation systems. They require imagination and expertise in the design and implementation of monitoring mechanisms and analytical tools. The efficiency of operation depends on the investment in quality of the reference databases, and on extortion of their compatibility with the other data. It requires a major effort, but it can give synergistic effects of unusually rich source of information supporting planning, spatial management, decision-making, and research.

Nobel Economic Laureates and the "Performance" of Cities

David C. Prosperi

(David C. Prosperi, Florida Atlantic University, Fort Lauderdale, FL, USA, prosperi@fau.edu)

1 ABSTRACT

Cities are, according to complexity theorists, emergent patterns that result from how a variety of economic, environmental, political and social forces act out. The collected work of two Nobel Laureates in Economic Sciences – Paul Krugman (2008 winner) and Elinor Ostrom (2009 winner) in relation to the liveability, healthiness, and prosperity of contemporary and future cities is examined. Krugman's "trade theory" focuses attention on the self-organizing result of a polycentric economic structure within urban regions. Ostrom's "on the commons" provides a powerful alternative to public policy and government led participation processes by showing how more efficient, equitable, and responsive such alternative systems are. The paper reviews both the basic arguments of the Nobel Laureates and develops some pragmatic approaches to the use of their thinking regarding the workings of basic economic, environmental, political, and social forces.

2 A "COMPLEX" METAPHOR OF THE CITY

The hope for "cities for everyone" – cities that are liveable, healthy, and prosperous – requires at the initial stages some discussion of two notions: how cities function (their internal dynamics) and how these dynamics perform. Planners – especially those whose practice lies at the intersection of real estate, ICT, and the general planning function – should focus at a minimum on improving the functioning of these internal dynamics. Performance as a general concept is an improvement in a value of some attributes, parameter, or resultant of some temporally dynamic process. The unanswered question, of course, is what are these dynamics and how should they be described, categorized, and eventually modified.

Arguably, foremost amongst these dynamics and resulting performance is the economic dimension. A function that operates simultaneously on at least two scales: the individual and the aggregate. How to capture this dual characterization in a single framework has perplexed both academic and practitioners.

To overcome rather rigid and constrained economic models in common use by planners, complexity theorists (e.g., Prigogine 1967; Bak 1996; Portugali, 2000; Batty 2005) have begun to conceptualize city dynamics as complex systems. Complexity theory brings a new language to the table. The new language is both provocative (sounds good!) and overcomes a set of nagging methodological problems facing planners in their attempt to modify behaviors to achieve societal-desired outcomes. Complexity theory is based on a systems representation of economic, environmental, political, and social forces. What is observed in the aggregate is termed an emergent pattern; things such as average travel time to work, aggregate GDP, mean "sustainable GDP", average "granularity" of the road network, etc. The key to complexity theory is that it provides a mechanism – normally stated as "complex adaptive systems" expressed as either agent-based models or more simple multiscalar hierarchical processes – to link the behavior of individuals to these aggregate patterns. Thus, individual behavior identifiable, measurable, and changeable at the scale of the individual produce patterns at the scale of the aggregate.

While not complexity theorists per se, the two most recent winners of the Nobel Prize for economic sciences – Paul Krugman in 2008 and Elinor Ostrom in 2009 – have significant "complexity thinking" in their work. Krugman's "trade theory" focuses attention on the drivers and forces that result, when applied in the metropolitan context, in polycentric economic structures. Ostrom's "on the commons" focuses attention on the adaptive design and self-organization of institutional arrangements in the provision of services. While their approaches are almost at opposite ends of the "truth-finding" scale (Krugman is arguably portrayed as a popular-economist, Ostrom is arguably portrayed as an experimental-economist), both Laureates focus attention on individual motivations and behavioral processes that ultimately give rise to aggregate emergent patterns, which could be the basis of various indicators of the performance of cities. The intention of this paper is to examine the work of these two recent Nobel Laureates in the context of the contemporary urban/metropolitan condition. What does their work instruct us to think about, what are the practical realities, and what is the guidance imminent. Thus, this is a purely speculative theoretical paper, intended to expose these new ideas and generate alternative mindsets and perspectives.

The paper has a simple structure. In the next two sections, the major works of Krugman and Ostrom are identified, briefly reviewed and illustrated. The penultimate section extracts six talking points, three from each Laureate, about contemporary urban/metropolitan conditions and performance. The final section is both a mini-reflection of the exercise and an attempt to lay down the challenge for future research.

3 PAUL KRUGMAN (NOBEL ECONOMICS LAUREATE, 2008)

Paul Krugman was born February 28, 1953 (so he is now – as of this presentation in May, 2010 – 57 years of age). He grew up on Long Island in New York, received a BA in economics from Yale University in 1974 and a Ph.D. in economics from MIT in 1977. He is currently a professor of economics and international affairs at Princeton and a centenary professor at the London School of Economics. Krugman is also a member of the Council of Foreign Relations, a research associate at the National Bureau of Economic Research, and a member of the Group of Thirty. But perhaps most visibly, he is a regular columnist and blogger for the New York Times and calls his blog "The Conscience of a Liberal".

"The Nobel Prize Committee stated that Krugman's main contribution is his analysis of the impact of economies of scale, combined with the assumption that consumers appreciate diversity, on international trade and on the location of economic activity. The importance of spatial issues in economics has been enhanced by Krugman's ability to popularize the complicated theory with help of easy-to-read books and state-of-the art syntheses … [they state] 'Krugman was beyond doubt the key player in 'placing geographical analysis squarely in the economic mainstream' and in conferring it the central role it now assumes''. The provocative title of his Nobel address is "The Increasing Returns Revolution in Trade and Geography" (http://nobelprize.org/nobel_prizes/economics/laureates/2008/krugman-lecture.html, 44 minutes).

Five key elements of Krugman's oeuvre are examined. These include: (1) the 1991 Journal of Political Economy article that contains the original thinking about the increasing returns process; (2) the 1995 book Self-Organizing Economy that focuses on cities and regions; (3) elements of the "new economic geography"; (4) the original foray into becoming a macro-economic critic; and (5) the continued writings.

3.1 Journal of Political Economy (1991)

Krugman's most cited academic paper (857 citations by early 2009 according to Wikipedia) is an article title "Increasing Returns and Economy Geography" published in the Journal of Political Economy in 1991. The major thesis of this paper is the creation of a formal model that results in the observed pattern of regional divergence of specialized activity. That is, there are observed patterns of concentration of economic activities. The major advance of the formal model is explicit consideration of pecuniary externalities. Interestingly, even in 1991 in a formal academic press, Krugman's first major section is an "intuitive" model, perhaps pre-saging his current career as a columnist and journalist.

Economic modelers rely on a set of assumptions. Here, the location of economic activity is based on the interaction of "economies of scale" and "transportation costs". The eventual pattern of economic activity rests on a few key parameters. Both the intuitive and formal model rest on the simple assumption that economic actors will tend to locate in areas of larger potential consumption and that that part of the consumption is other producers. This is the "circular causation" or "positive feedback" effect of self-organizing systems. Krugman not only considers "backward linkages" common to understanding production systems but also "forward linkages" that argue that it "is more desirable to live and produce near a concentration because it will less expensive to buy the good this central places provides." Thus, demand becomes almost endogenous.

In this model, short and long-term equilibrium rests on only three factors: the share of expenditures of manufactured goods; the elasticity of substitution among products; and the fraction of good shipped that arrive. These factors create the ultimate explanatory variable, real wages (as opposed to nominal wages) defined in terms of both wages and differences in prices.

3.2 The Self-Organizing Economy (1995)

Krugman is even more explicit in The Self-Organizing Economy (1995) which focuses almost entirely on urban and/or metropolitan areas. The rather short (100 pages without the technical appendix) text is divided into two parts: "embryos, earthquakes, and economics" and "self-organization in time and space". In this book, the fundamental methodological perspective is the concept of self-organizing systems. Self-organizing

systems are those, in which seeming randomness and chaos at one scale of resolution evolve into unexpected order at another level of resolution or, put another way, produce "order from instability". The argument is quite simply and clear: the "economy" and "the spatial economy" of urban/metropolitan regions are self-organizing systems. The importance of the book is that this is the first time a [spatial] economist invoked with such force this notion. Simply put, Krugman develops a way to look at what he calls "urban morphogenesis" (p. 49). The notions of order from instability and order from random growth apply.

"Order from instability" relies on three properties of systems: complexity, emergence, and self-organization. Complexity is based partially on the insight that feedback mechanisms have surprising properties, including positive (reinforces the process) and/or negative (dampens the process) feedbacks. Emergence is about how large interacting ensembles – where the original units may be water molecules, neurons, magnetic dipoles, or consumers – exhibit collective behavior that is very different from anything you might have expected from simply scaling up the behavior of the individual units. Self-organizing systems are systems that, even when they start from an almost homogeneous or almost random state, spontaneously form large-scale patterns.

Finally, Krugman argues that complexity and self-organization are value and ideological-free concepts. Neither is necessarily or presumptively a good thing. So, books like Order out of Chaos (Prigogine, Stengers & Toffler, 1984) or Complexity: Life at the Edge of Chaos (Lewin, 1992) are really about method, not about normative prescriptions for a better society. Simply, systems exist, have properties, and contain drivers of change.

3.2.1 Embryos, Earthquakes, and Economics

Part one is focused on how the twin principles of "order from instability" and "order from random growth" can be applied to modern spatial economic theory. The chapters have provocative names: "self-organization in space", "complex landscapes", "an urban mystery", and "principles of self-organization".

Krugman starts the discussion with the traditional VonThunen/Alonso/Mills model and the notion of bid-rent curves and shows how these models do not reflect reality. Central place theory works better as a descriptive device, but lacks economic content. Finally, he shows the wisdom of the Shelling book Micromotives and Macrobehavior (1978) in which "mild preferences about ones neighbor" create "high degrees of segregation at the scale of the metropolis". Simply, local, short-range preferences and actions create large-scale structures. Using an agent-based model based on this notion and two criterion related to centripetal and centrifugal forces, Krugman is able to demonstrate a polycentric urban spatial structure. The second major concept of this first part is "order from random growth". Here, Krugman demonstrates the power of positive feedback and circular causation that result in explanations of known Power-function regularities.

3.2.2 Part Two

Part two is focused on self-organization in time and space. Once again, the chapters have provocative names: "dynamics of self-organizing systems", "temporal self-organization", and "models of spatial self-organization". The two major advances here are the explicit treatment of time, largely ignored in the "comparative statics" nature of much economics research. Krugman creates explicit temporal variations for a number of predominately spatial models.

The second major achievement is that Krugman develops complexity arguments that could improve understanding of the observed realities of such common planning and/or theoretical ideas such as Edge Cities, Central Place Theory, and Zipf/Simon Power Law. The key in terms of most of this is positive feedback and spillovers that create their own emergent property (of growth!).

3.3 New Economic Geography

The results of the Self-Organizing economy gave rise an energetic field of inquiry called the "new economic geography." The major reader in this field is The Spatial Economy (Fujita, Krugman and Venables 2001). In a review in the Oxford Review of Economic Policy, Krugman (1999) solidifies the work that focuses on the notion that one can clearly derive aggregate behavior from individual maximization.

The basic ideas of the new economy geography lie in a complexity theory formulation are other embedded aspects, including notions of how historical accident could shape contemporary geographies, how small and gradual changes in basic parameters that guide individual behavior can produce discontinuous changes in

spatial structure, and the principle idea of circular causation based on the relative strength of both centripetal and centrifugal forces.

3.4 Becoming a Macroeconomics Guru

Krugman is probably better known for his contributions to macroeconomics than for his contributions to the new economic geography, although it is the former that was cited in the awarding of the Nobel Prize. He has examined the trade theory that works at the scale of the firm (and maybe the city) and created a set of macro-economic perspectives. Two major books are discussed below.

What makes Krugman so popular (and perhaps so despised, if you are a fan of Taleb) is that many of the books about macroeconomics are written in a popular style (i.e., actual or perceived avoidance of any real economic content). Throughout the years, Krugman has distinguished between academic economists (who write for other academic economists) and other economists like "policy analysts" and "journalists" who write for a broader public and politicians. Krugman is, somehow, perceived in most quarters as an "intellectually honest" economist, praising both the right and the left.

3.4.1 Peddling Prosperity

In the book Peddling Prosperity (1994) Krugman aims at "nonsense" from both the conservative and liberal camps. But, the main target is supply-side economics and strategic trade relations (as opposed to market and free trade). His basis of argument is orthodox, neoclassical economic analysis; he calls himself a "New Keynesian. Though Krugman is a liberal, he is capable of praising both the right and left. The major point is that economic science still has limited knowledge and that the notion of tradeoffs in economic policy is too often ignored – on the right and on the left.

Krugman then goes on to suggest how policy entrepreneurs have succeeded in convincing politicians that big government with high taxation and excessive regulation hinders growth and that supply-side (tax cuts) would stimulate growth, raise investment, and enable deficit reduction. The empirical part of the book, covers the 70s and 80s refutes all claims and left the US economy with a wider income gap.

3.4.2 Age of Diminished Expectations

Age of Diminished Expectations (1999,3rd ed, 1994, 1990 by the Washington Post) is broader in scope. The major theme is that the US economy has performed poorly (in the 70s and 80s), that better performance is unlikely, and that the public seems oddly complacent. Set against the three major determinants of economic well-being – productivity and income growth, income distribution, and employment, Krugman argues that the US has done well in job creation only. The consequence is that Americans have accepted low growth and income disparity. Moreover, there is little public support for massive policy changes and he doubts the ability of government to produce such changes, even if the political will was there.

Krugman identifies three scenarios: Happy Landing (probability = .20) is a return to the growth of the 50s and 60s; Hard Landing (probability - .25) is a loss of faith by foreign investors in the US economy and a cut-off of capital exacerbating the debt crisis; and Drift (probability - .55) describes sluggish productivity, lower unemployment, and higher inflation combined with growing problems of the underclass leading to the US sinking to "third rank" as an economic power.

3.5 The Continued Writings of a Popular Writer

Krugman's The Accidental Theorist (1999) and Conscience of a Liberal (2007) are accessible compilations of the perspective. He continues to write; the latest books are The Return of the Depression Economics and the Crisis of 2008 (2008) and A Country is Not a Company (2009) as well as a series of story-driven college level textbooks (Krugman and Wells, 2008, 2008, 2009).

4 ELINOR OSTROM (NOBEL ECONOMICS LAUREATE, 2009)

Elinor Ostrom was born August 7, 1933 (so she is now – as of this presentation in May 2010 – 76 years of age). She grew up in southern California, received a BA (with honors) in political science, a MA in 1962, and a Ph.D. in 1965, all from UCLA. She is currently on the faculty of both Indiana University (Arthur F. Bentley Professor of Political Science and Co-Director of the Workshop in Political Theory and Policy Analysis) and Arizona State University (Research Professor and Founding Director of the Center for the

Study of Institutional Diversity). Ostrom is a member of the US National Academy of Sciences and past president of the American Political Science Association, the first women to receive the prestigious Johan Skytte Prize in Political Science in 1999 and the William H. Riker Prize in political science in 2008 in addition to the James Madison Award by the American Political Science Association in 2005and the Risch Civic Engagement Prize from the Jonathan M. Tisch College of Citizenship and Public Service at Tufts University in 2009 (http://en.wikipedia.org/wiki/Elinor_Ostrom).

The Nobel Prize Committee cited Ostrom "for her analysis of economic governance" saying that her work had demonstrated how common property could be successfully managed. Common resources include things such as forests, fisheries, oil fields or grazing lands. The central theme of Ostrom's work is that these resources can be successfully managed by the people who use them; in contrast to the more normal management strategies focused on either state or market. The provocative title of her Nobel address was "Beyond Markets and States: Polycentric Governance of Complex Economic Systems" (viewable at http://nobelprize.org/nobel_prizes/economics/laureates/2009/ostrom-lecture.html).

Ostrom's work is examined at four junctures. These are: (1) early work on identifying the "rational choice model" of inquiry for the study of public goods and common-pool resources; (2) maturation of the concept and measurement resulting in the classic book Governing the Commons (1990); (3) the concept of governance polycentricity and understanding institutional diversity; and (4) continued work, including the IASC organization, which continues the approach to public and common-pool resource evaluation.

4.1 The Study of the Public Goods and Common-Pool Resources

In a series of early papers, Ostrom and her colleagues systematically develop their "institutional analysis and development" (IAD) framework based on principles of rational choice theory. There are two basic questions: what is to be managed, and how to study systems that do the managing.

4.1.1 What is Managed

Ostrom, and others, argues that there are various types of goods and services. Public goods are those "that yield non-subtractable benefits that can be enjoyed jointly by many people who are hard to exclude from obtaining these benefits. Common pool resources are those who benefits are hard to exclude but each person's use of a resource system subtracts units of that resource from a fine amount available. When a fisher harvests a ton of fish, those fish are not available to any other fisherman.

4.1.2 Approaches to Studying Management

In her Nobel interview, Ostrom is very candid in stating that after spending years looking for "the answer" to efficient, equitable public management, there was none. In the absence of a single answer, Ostrom developed an approach – the institutional approach to studying the provision of public and common-pool resources. Ostrom's ultimate contribution is that there are multiple solutions to the provision of public goods and common pool resources and that the problem is getting the institutions right.

Since situations vary, the problem is one of finding the correct, successful, mixture of "public-like" and "private-like" solutions. By successful, Ostrom means institutions that enable individuals to achieve productive outcomes in situations where temptations to free-ride and shirk are ever present. There is a clear call for an assessment of the efficiency and equity of institutional arrangements. And, there is a clear proposition that, while messy, one can assess the relationship between institutional arrangements and performance. The key is in the details.

4.2 Governing the Commons (1990) and Understanding Institutional Diversity (2005)

Ostrom begins Governing the Commons with an explanation of the overarching methodology of her career. Ostrom, quite succinctly, discusses three "influential models" in the study of public policy questions: the tragedy of the commons (Hardin, 1968), the prisoner's dilemma (Dawes, 1973), and the logic of collective action (Olsen, 1965). These metaphors for public policy debate form the basis of most, if not all, organizational theory characterizations of the public arena. Then, she clearly identifies the two extreme policy positions: state and market. At the extreme point "state" the case is made for Leviathan type institutions; at the extreme point "market" the case is made for privatization. While ideologues gather at

extremes, arguing for either a solution based on large, coordinated and regulated government agencies or privatization, the major point is that in practical contemporary terms we have is a set of mixed models.

4.2.1 The Institutional Approach to Study Self-Organization and Self-Governance

Ostrom begins with the notion that individual behaviors are complex, and particularly so in uncertain situations. Next, she argues that there are certain adverse outcomes of independent action (as above). The "general problem" is "solved" by external agents in two well accepted theories: the theory of the firm and the theory of the state. Note the difference in terminology, particular in the first. She substitutes "theory of the firm" for "private market". This is a key point, more fully explained immediately below.

In both scenarios, the emphasis is on how institutions are supplied, how commitments are obtained, and how the actions of agents and subjects are monitored effectively, using in one case the firm, and in the other state, as an organizational device. How a group of principals – a community of citizens – can organize themselves to solve the problems of institutional supply, commitment and monitoring is still a theoretical puzzle."

4.2.2 The IAD Framework

The institutional approach is captured, both conceptually and for measurement purposes in the institutional analysis and development framework. Here, Ostrom and her colleagues developed a representation of the flows. The model "looks like" a normal production function from a classical microeconomics textbook, except that virtually nothing in under the singular control of a single producer. Two important items are outcomes and rules. Ostrom and Ostrom (2004) identify six outcomes: economic efficiency, equity through fiscal equivalence, redistributional equity, accountability, conformance to general morality, and adaptability. Evaluative criteria are simply numerical measurements for these underlying conceptual dimensions. What is important is that outcomes are identified and clearly part of an analytical system in which varying levels of inputs and flowthrough produce outcomes. A representation of this model is shown in Figure 1

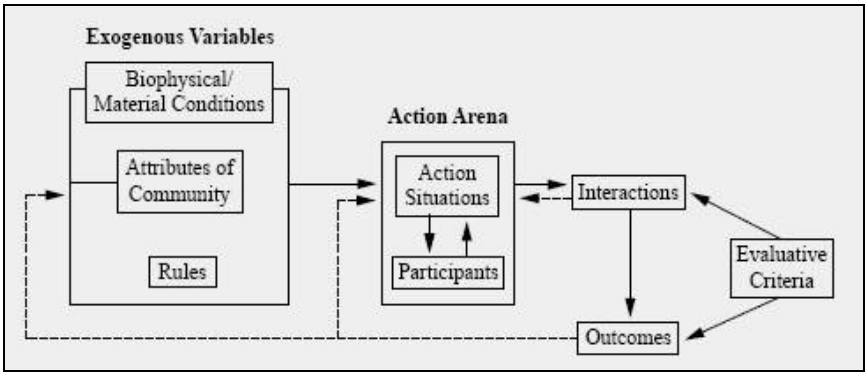

Figure 1: The IAD Framework (Source, Ostrom, 2005, p. 15)

4.2.3 Eight "Design Principles"

Ostrom defined eight "design principles" of stable local common pool resource management. Because they have been reproduced virtually everywhere, I include them here. They are:

- 1. Clearly defined boundaries (effective exclusion of external un-entitled parties);
- 2. Rules regarding the appropriation and provision of common resources are adapted to local conditions;
- 3. Collective-choice arrangements allow most resource appropriators to participate in the decision-making process;
- 4. Effective monitoring by monitors who are part of or accountable to the appropriators;
- 5. There is a scale of graduated sanctions for resource appropriators who violate community rules;
- 6. Mechanisms of conflict resolution are cheap and of easy access;
- 7. The self-determination of the community is recognized by higher-level authorities; and
- 8. In the case of larger common-pool resources: organization in the form of multiple layers of nested enterprises, with small local CPRs at the base level

The key point is that these are not "guidelines" or "blueprints" for developing a self-organizing governance system, but rather principles by which to assess them.

4.3 Polycentricity

The earlier arguments were developed by V. Ostrom (date), who relied on the original insight of Polanyi (1951) who had identified two different methods for the organization of social tasks: directed order (top down!) and spontaneous or polycentric order. V. Ostrom argues that "a spontaneous or polycentric order is one where many elements are capable of making mutual adjustments for ordering their relationships with one another with a general system of rules where each elements acts with independence of other elements" (date, p. 57). From here, it is possible to pose a series of empirically verifiable questions: (1) what is the relationship between the scale of provision and the scale of governance; (2) how do people choose among various governance opportunities within a metropolitan region; and (3) size matters systematically for problems of efficiency, effectiveness, equity and responsiveness.

These questions are formulated as a set of complex relationships and rules. The theory of governance polycentricity is a systems theory framework, more a hierarchical systems theory. Management of hierarchical systems occurs at multiple points; so for example, such systems do not necessarily need to be managed from a top down perspective.

Almost as a testament to her considerable curiosity, Ostrom began work with a series of systems modelers at Arizona State University. Moving from a more qualitative field work approach that characterized her work in natural resources in developing countries, now the task was to try to model – via complexity models – the behaviors of such governance systems. This work is captured, for example, in a series of articles in Ecological Economics and Ecology and Society (Wilson, Low, Costanza and Ostrom 1999; Gibson, Ostrom and Ahn 2000; Anderlies, Janssen and Ostrom 2004; Janssen and Ostrom 2006).

4.4 The International Association for the Study of the Commons (IASC)

The Ostrom "challenge" has been taken up by IASC (http://www.iascp.org), founded in 1989 that aims to understand and improve institutions for the management of resources that are or could be held collectively by communities. Historically focused on developing countries and natural resources, the current focus is on exchange of knowledge, mutual exchange, and the promotion of appropriate institutional design in a widening range of commons including things such as digital commons, intellectual property and copyrights, biodiversity, climate change, and other "urban commons" (van Laerhoven and Ostrom, 2007).

5 WHAT DOES IT MEAN? A DISCUSSION OF THE RELEVANCE OF ABOVE

So, what does all this "theory" mean to the creation of liveable, healthy, and prosperous cities. In this section, limited by space, I offer three major talking points for each of the Nobel Laureates. The first three emanate from the work of Krugman; the last three from Ostrom. Here, I provide a direct tie-back to the introductory remarks regarding cities as complex organisms as well as provide some references to contemporary work for each of the these talking points.

5.1 The Polycentric Internal Spatial Structure of the Metropolitan Region Matters

Most conceptions of the internal structure of metropolitan regions are, for lack of a better phrase, oversimplified. The usual suspects "core-periphery" "center city-other" and even "themed spaces" are poor metaphors for the reality of metropolitan spaces. In such a milieu, both academics and policy entrepreneurs tend to focus on one of these themed spaces as those were the only driving forces of urban development. Thus, we get a focus on "global business districts" that are "in the center" but have none of the characteristics of a "center" except in hyper spaced networks of such places and/or "airport cities" as some new form of urban development. Few of these studies even attempt a relationship between their signification and the three fundamental attributes of economic well-being: productivity, income distribution, and employment.

The real value of the Krugman argument is that metropolitan regions are composed of numerous subcenters, specialized within and functionally different among themselves. All are necessary. They create patterns of trade (the most obvious being between worker and residence). While these employment nodes may contain some housing and vice versa, it is naïve to think of a world of perfect little Howard "town-country" places.

The line of thinking is best reflected by Bogart (2006) and others who are clear in that these sub-centers are functionally specialized and different. Some of these sub-centers – like the central business district – are even further specialization and functionally different (Prosperi, Ozbakir & Erol, 2010).

5.2 Complex Adaptive Systems (Agent-Based, Multiscalar)

If there is a single word phrase that captures much of contemporary urban/metropolitan theorizing, it is "complex adaptive systems". This approach lies at the core of human-ecological conceptualizations (Alberti, 2008); urban/metropolitan economic spatial structures (Batty, 2005), and planning (Innes & Booher, 2010). The key methodological perspective is that there exists "agents" (people, institutions) that act as individuals in a definable way, including aspects of behavior in or control of space. Agent-based models focus on what happens when these agents are allowed to "act out" over time and space. The result is an aggregated pattern, which complexity theorists call a state of emergence.

Moreover, the properties of the emergent pattern may or may not be what would be expected by simple extrapolation of individual actions. Krugman retells the results of Schelling that demonstrate that only very mild preferences for social segregation at the individual level create widely segregated metropolitan spaces. The pattern observable at the higher or larger scale is both dependent (through other forces such as feedbacks) on the individual motivations but also independent (through thinks like non-linear and discontinuous processes). The overall process is multiscalar – behaviors at one level of resolution having observable behaviors at another level of resolution. This point cannot be made strong enough.

Regarding the urban/metropolitan debate, this approach suggests a meta-question: it the debate about individual lives or about the aggregate? This question is often overlooked. What it means for planning is that planning must focus its attention on the behavior of agents: individuals, groups, etc. in an attempt to change behaviors. The patterns that are observed – average GDP – are the result of individual agents acting out their behaviors. The fix must be at the scale of the agent, not at the scale of the aggregate.

5.3 Good Politics, Bad Economics … at the Metropolitan and Local Level

The tendency to base policy (and planning?) on the ideas of "policy entrepreneurs" is seen by Krugman to be almost dangerous. While he uses the phrase "good politics, bad economics" in discussion of national level economic policy, the question here is: does this phrase have meaning at the urban/metropolitan level.

Much of what passes for economic policy at the urban/metropolitan level is copycatting of popular, but unproven, manifestos, normally emanating from the popular press. Witness the craze, for example, about the "creative economy" (e.g., Florida, 2001) or the "pulsar effects" of large institutional or sporting events (ISOCARP, 2002). Simply put, the empirical evidence about the relationship between these "economic policies" and the economic criteria of productivity, income distribution, and employment is scanty, spotty, and may even be regressive (particularly in the case of large-scale publicly financed "games").

5.4 The Polycentric Structure of Metropolitan Governance

Metropolitan governance is a hot issue (e.g., OECD 2001, Feoick 2004, Salet Thornley and Kruekels 2003, Heinelt 2005) particularly outside the US. It represents Ostrom "messiness" and Ostrom "truth".

The new found reality is that the concern about how metropolitan areas are governed is still an open question. What is clear is that these large urbanized settlements are governed not by a government but rather by a nebulous set of institutional actors and relationships. The recent joining of the terms governance with social and/or territorial capital – both hard to pin down concepts – continues an unnerving tendency to "chatter". Under these circumstances, it is not surprising that Salet, Thornley and Kruekels (2003) major conclusion is that there is no best model or framework.

Normative-assertions and story-telling is not enough; empirical relationships need to be verified. Heinelt's story of the "Hannover Miracle" – a joining of public service provision by several levels of government – is a miracle only by proclamation. Collaboration for collaboration's sake (e.g., Innes and Booher, 2010) makes only very limited pragmatic success without observable improvements in the condition of something. Where are the relationships between the institutional structures and Ostrom and Ostroms's six evaluative criteria (economic efficiency, equity through fiscal equivalence, redistributional equity, accountability, conformance to general morality, and adaptability)? A new public economics is needed.

5.5 Performance through Institutional Design

There are two possible intuition pumps here. First, organizational behaviors and institutional arrangements matter. And, second, that this is really a matter of designing complex adaptive systems for individual cases and situations. In either case, the emphasis is on performance.

Europe, in particular, is witnessing the effects of changes in institutional arrangements and organizational behaviors. Due in part to a greater reliance on government interventions (a larger expectation that "government" will fix it), the structure and functions of the EU bureaucracy is the subject of much interest and research. But, the issue is more general than just whining about EU policies and frameworks. The problem is on the ground in metropolitan regions. What are the institutional arrangements in Vienna, or anywhere? Once we get away from economic competitiveness as an object of evaluation (sic), there are few studies that relate such arrangements to more normal primary (Krugman) or primary-plus (Ostrom) criteria.

Second, it is becoming clear that much existing policy frameworks, on the ground, have not yet adopted the complexity driven arguments of systems theory. Copycatting does not work.

The large point is that the institutional analysis approach is useful for the study of contemporary situations, as earlier work on policing has demonstrated. The new "Ostrom challenge" should be the application of her and her colleague's methodology to contemporary urban service delivery.

5.6 It is about the Questions, Not the Rules or There Are No Rules, Only Questions

In her Nobel interview, Ostrom recalls years of frustration in searching for a universal rule or a universal truth! Instead, in the end, she concluded that it is about the questions rather than a set of guidelines of rules. What stands out in the Ostrom oeuvre is a very simple set of elements, all of which must be present. These are: (1) the creation of a conceptual model; (2) a model based on complexity; (3) an empirical approach; (4) concern for outcomes. The IAD framework is a framework for asking questions, finding local truth, and finding interventions that matter in the sense of improving performance.

Consider water. Water is rarely considered as a system; instead we compartmentalize the "water issue" into neat little categories like "water supply for drinking", "pollution and runoff", and "flood control". Today, institutional structures are fragmented (i.e., the Water Directive and the Flood Directive). Would not an institutional approach, developed along the lines of the Ostrom models above, re-focus how we think about water. Such an approach would allow identification of "polycentric" points of governance or "multiple places of responsibility", relating to system functioning. Evaluative criteria follow directly.

6 CONCLUSION

Three arguments have been made and illustrated. First, I briefly argued that contemporary urban/metropolitan communities are better characterized by complexity notions that by simplistic models. Second, that there is something to be learned from an examination of the work of those who have achieved the notoriety of the Nobel Committee – in this case the work of the two most recent winners of the Economics Prize, Paul Krugman and Elinor Ostrom. The quandaries, theoretical premises, and methodologies of these two thinkers have been exposed and reviewed. Finally, I have identified six areas of research and/or planning that could be enhanced by understanding the simply dynamics of the theories of the Nobel Laureates, particularly in relation to the questions of this conference: liveable, healthy, and prosperous communities.

The Nobel Laureates are very different. Despite his earlier de-bunking of "policy entrepreneurs" from grounding in complexity theory, Krugman has become a "policy entrepreneur". He is a prolific writer of "easy to understand" macroeconomic texts. Others in this tradition include Thomas Sowell (http://www.tsowell.com/), the Freakonomic's (http://freakonomicsbook.com/), Fareed Zakaria (http://www.fareedzakaria.com/) and/or Thomas Friedman (http://www.thomaslfriedman.com/). This tradition is akin to the emerging tradition of popular urban writers such as David Brooks, James Kunstler, and historically even Jane Jacobs or popular writers of scientific puzzles such as Nassim Taleb (http://www.fooledbyrandomness.com/) or Leonard Mlodinow (http://www.its.caltech.edu/~len/). [Someone should do a course on these guys/gals. The same argument is made here for the general public.] Yet, Krugman has failed to take his complexity thinking to the macro scale, especially at the national level. His lack of theoretical treatment of these macro systems and his lack of detailed empirical analysis almost

defines him, and leads to criticism. Ostrom, on the other hand, is more of an academic and engaged in the local community. Her thinking over the years has become more complex and more abstract but within the context of improving local conditions. Ostrom's inner strength comes from a fundamental belief in the capacity of individuals and local organizations to find what is best for them. But, in either case, what has been provided here is really only a "chapter 1 understanding" of both; as should be clear, it is the oeuvre that counts, not the individual event. It is probably the same for communities, cities, and regions.

Six research themes were proposed. Simplifying even further and focusing on the scale of the metropolitan region, there are two word phrases that stand out. These are: polycentricity and complex adaptive systems. I, at least, find it interesting that two usages of the term polycentricity have emerged: the spatial and the a-spatial. The spatial is reflected in land use patterns and concentration of specialized and differentiated nodes. This is the view of Anas et al. (1998) and Bogart (2006). The a-spatial is reflected in the web of governance at this territorial level which contains overlapping competencies and interests. This is the world of Salet, Thornley & Kruekels (2003), Innes and Booher (2010), Heinelt (2005) and the OECD (2001). [Parenthetically, the EU uses the word in both meanings. It is clear that an adjective is needed]. The second key idea, complex adaptive systems, is a useful phrase to describe the fundamental process that individual motivations and processes (across the spectrum of economic, environmental, social, and government systems) work and how they are aggregated to produce patterns evident at higher levels of resolution. Change in a level of performance – of economic, environmental, or governmental system – is probably best accomplished by changes at the individual level. Characterization of functions as complex adaptive systems allows points of intervention – and hence governance – to be realized and analyzed.

So, here, we have the basis for action. Thus, it is not a set of universal guidelines for structure; rather, it is a set of universal sets of questions about process. It is about the questions and the ultimate tie to performance of our communities. The new challenge for academics, planners, and policy makers is to improve our thinking about public goods and services, including new ones like "knowledge" (Hess and Ostrom 2007) in a continuing effort to create liveable, healthy and prosperous communities, cities, and regions.

1 ABSTRACT

The contribution intends to present the importance of green spaces in the urban structure, their meaning for ecological and social quality in the city and their importance for the economic value of properties. It gives an overview on the originating of brownfields – urban waste land and the chance and opportunity to use them for improvement of urban districts. Two specific aspects were regarded more detailed, the importance of the integration of the inhabitants in the reuse process and the meaning of green spaces for the land value. By presenting examples of different German cities, the authors specify these aspects and point out the importance to include those in the urban planning process. The combination of social activities and economic factors occupies an important role in the sustainable urban planning process and how to consider them can be an advice for other cities.

2 BROWNFIELDS/ URBAN WASTELAND/ ABANDONED OR UNDERUTILIZED LAND, BACKGROUND

The growing number of urban wasteland is a worldwide phenomenon and has different reasons often they are the result of an economic change. In general, it is combined with a loss of population. Due to political and economic reasons parts of cities fell and still fall apart and thereby create a specific planning and development problem. We can find examples in Germany, in the Ruhr Area and the New Bundesländer; in Great Britain, we can find them in Manchester and Liverpool; in the USA, e.g. in Detroit and it is Osaka in Japan, we find them even in the Russian Federation, in Ivanovo (ATLAS OF SHRINKING CITIES 2006). An example of a shrinking due to geographical circumstances we can find with New Orleans (flooding) or the Chittagong Region (storm). But often we see a recovering of these cities.

In general we find the decreasing population in industrial countries, while the population in the developing countries is growing, combined with an enormous demand of open space. In these city regions, the problem is more one of the low quality of residential areas and therefore the question how to improve these quarters and how to do this ideally together with the inhabitants.

As a result of an experience phase of more than two decades we can learn from the so called old industrial countries how to deal with:

- The problem of industrial brownfields – which will be also created in developing countries - with a lot of serious pollution.
- The decreasing quality of residential areas due to social problems.
- The abandoned, empty residential areas, caused by a moving and declining population.

The question is how to stabilize these parts of the city, often well-equipped with infrastructure, but with a negative image and undergoing a severe demolition process.

To redevelop the inner city areas also helps to avoid the process of urban sprawl. One of the main goals in the Federal Republic of Germany is to reduce the land use from ca. 100 ha per day down to 30 ha per day (DEUTSCHER BUNDESTAG 2004). To reach this goal German cities have to follow the “inner-development instead of outer-development” principal. That means that they have to use areas located within the built-up area and not at the fringe of the city. Developing and stabilizing these urban areas and to make them usable and attractive for new people and companies can be regarded as a part of sustainable urban development. Since the Rio Conference in 1994 sustainability is a general political objective in the urban planning process.

The following figure shows the elements of sustainability.

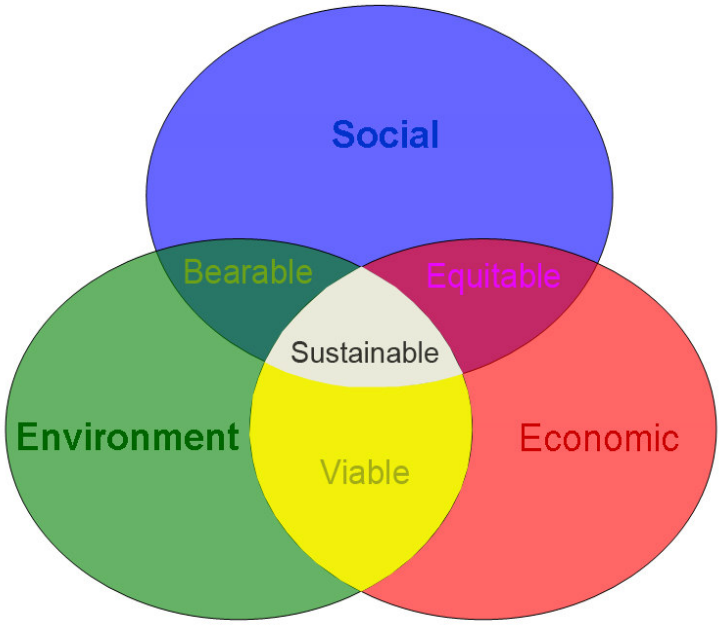

Fig. 1: Elements of Sustainability

Starting from the general definition of sustainability we can define: “Sustainable brownfield regeneration is the management, rehabilitation and return to beneficial use of the brownfield land resource base in such a manner as to ensure the attainment and continued satisfaction of human needs for present and future generations in environmentally non degrading, economically viable, institutionally robust and socially acceptable ways.” (Rescue 2005: 11)

Using a brownfield or an abandoned site for a new development has many advantages. The good quality of the site in ways of centrality, public transport connections and often the urban environment and neighbourhood are good reasons. On the other hand the costs of technical infrastucture for a community are the higher the lower the settlement density is: 1.400 €/year/ inh. for single family houses; 500 €/y/inh. for multi family houses in inner city. In times of low public budgets this is a good argument for inner city development. (FEDERAL ENVIRONMENTAL AGENCY 2003; BESECKE 2005)

In Germany the Federal Environmental Agency published a guide book with the title “The Future lies on Brownfields”, which is an information for investors and real estate owners. This guide book stresses the meaning of cooperation and public private partnership on the one hand and the importance of creating an environment with a high quality, including adequate open spaces. This is the base for the concept of green parks and gardens on city wasteland, implemented with the inhabitants.(F.E.A., ICSS, 2005).

The experience of 20 years of sustainable brownfield regeneration, not only in Germany, but also in Europe, can be used as a reservoir for ideas which could be transferred to other countries. It is not only the aspect of developing of already used land but also the requirements of sustainable treatment of the natural resources. The focus however of this contribution lies on the development of brownfields to green areas, the participation of people and the enhancement of the property value through a green environment.

3 FUNCTIONS OF GREEN SPACES

In many European countries a contradictory debate of the value of and the benefits from urban open spaces is going on. On the one hand, they are highly regarded not only due to social, ecological and health related matters, but also increasingly to economic benefits resulting from them. Above all, they are seen as a mean to counter act migration out of cities and, thus, the deterioration of wide parts of the city centres. On the outskirts, their importance for the attractiveness of areas of complex housing has recently been recognised, at least in Germany. Finally, the provision and the quality of urban open spaces increasingly represent an important soft location factor for cities particularly with regard to attracting companies to settle down (FLL 1999; LUTHER 2000).

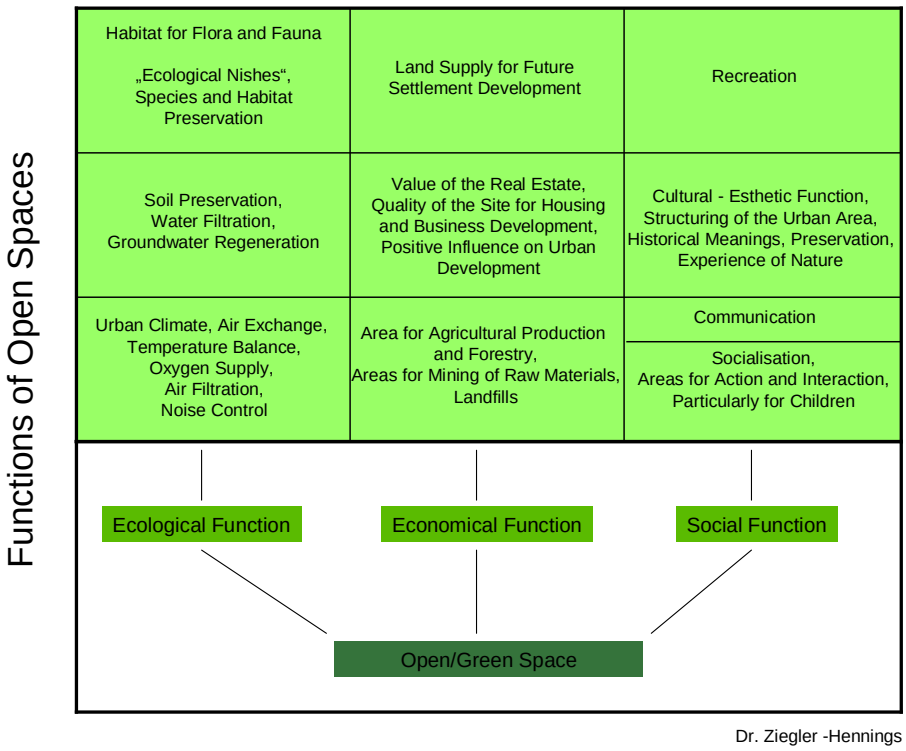

Fig. 2: Functions of open spaces

The social and economic function of open spaces often cause each other, even though they are sometimes in competition with the ecological functions.

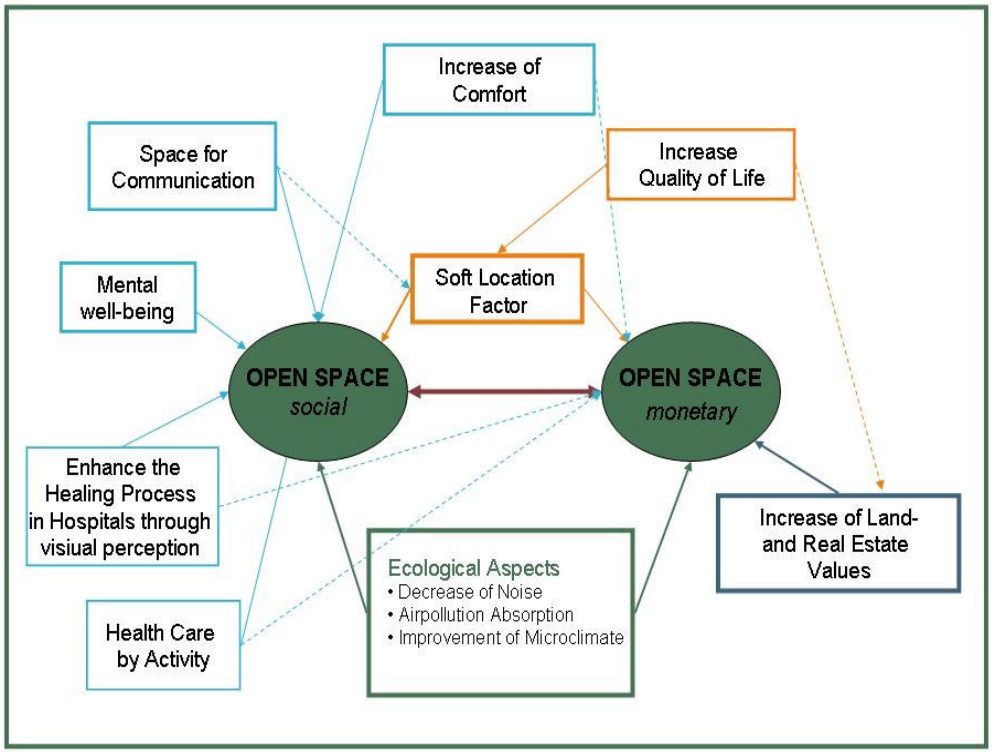

Fig. 3: Social and economic factors of open space

People are willing to pay a large amount of money to obtain property close to a park or any other kind of open space of a good quality. (SHERER 2006). The reason for this phenomenon is founded on the fact, that

living near to a green space can achieve many possibilities to do something for health and well-being and it allows the opportunity to socialize.

It is proved, that green space has a positive influence on human health and well-being. A study from the Netherlands has shown that looking out of a hospital room into the green significantly shortens the healing process of the patients.

Using green spaces is limited and determined by several factors, if they are not fulfilled green space has a very low social and economical impact.

These factors are:

- Accessibility within 10 minutes walk or biking,
- dimensions of green space, larger ones are more attractive than smaller ones,
- subjective feeling of safety and
- the attractiveness of the green space (playground, outdoor furniture, water…) (GÄLZER 2001)

The access to green space within a short walking distance influences the willingness of outdoor activities. If a person needs too much time to reach an open green space he will not use it.

Through the engagement in regular physical activity you can reduce the risk of premature death. If you enable the inhabitants of a city to gain access to a nearby open green space they are more likely to exercise and that supports the mental and physical well-being. (GIES 2006).

An urban green space is always a place of communication and a meeting point for different kinds of groups, for example, children, mothers with little kids or older people. Getting in touch with others is important for forming a community. Young families for example are very interested in getting in touch with other families to get their kids in contact. The importance of play because of the "playing is learning" idea is an important factor even for families with young children. They integrate this knowledge in their search for a home. (GIES 2006: 17). These are reasons for a location decision in the settling process.

Green is a soft location factor as mentioned before and shown in the figure 3 above. Mental well-being, communication and health are important parts of human life and so a lot of people are interested in supporting those functions. But as said before, the quality of the green area is important for those two functions of green. The park or green space, in other words, must be safe and of high quality. The definition of high quality is discussed in the case study, which is presented in chapter 5.

The entire above mentioned are reasons why green space has an economic function besides the social and ecological ones. People nowadays are willing to pay more money for more green. That causes an increase of land and real estate values. (GRUEHN 2006)

This increasing value of land and real estate prizes is not only valid for residential housing but also for commercial buildings. Ernst and Young showed this in a report they did for the "New Yorkers for Parks" Initiative. The Bryant Park, which was redesigned and reopened in 1992, for example, raised up real estate prices between 115 and 225 percent between 1990 and 2000. (ERNST AND YOUNG 2003)

4 GREEN DEVELOPMENT (WITH HOUSING) AND CIVIC COMMITMENT

There are different views and approaches regarding the combination of brownfields and open space planning. One view originates in the context of sustainable urban development and concentrates on the protection of greenfields and landscape at the border of cities through the development of brownfields. Another view stresses the development of biotopes with rare species on the brownfields site itself. In this context the brownfields should be defined as nature protection areas. A third view takes into regard the improvement of the environment in residential areas by creating new parks on abandoned sites.

As mentioned before, green spaces or parks have several functions for the inhabitants. Beside the improvement of the natural environment as water and local climate they play an important role for the recreation, for children's play and for social life. Therefore it is important to plan and to implement a net of residential open spaces, parks and green connections for pedestrians and cyclists. Green development of brownfields can contribute to these concepts. For economic reasons often a combination of housing and

green spaces is desirable. And there are many examples of successful neighbourhood of green and housing plots.

As a result of so many different social and economical circumstances the concepts demand a high flexibility. One main distinction exists between temporary and permanent use. The following figure shows the wide range of green uses. To maintain the green plots civic commitment and the cooperation with the inhabitants is important.

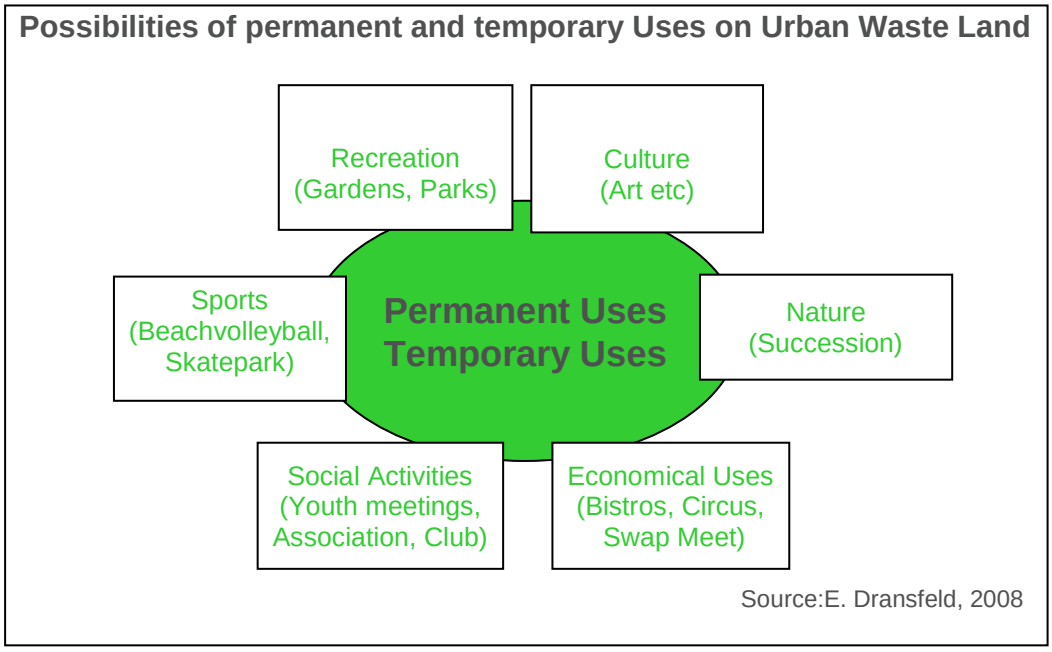

Fig. 4: Possibilities of permanent and temporary uses on urban waste land

In the following, three different approaches will be described concerning green space development (with residents) on brownfields - urban waste land:

- New green residential areas.
- Spaces for children's nature experience, wilderness for children.
- Temporary uses with citizens.

4.1 New green residential areas

As mentioned, the combination of housing areas and open spaces has many advantages. It causes a better quality of living and therefore people stay in the inner city. It increases the value of the property and guarantees a reasonable price. It even strengthens the identification of the inhabitants with their quarter and the willingness to care about green spaces.

In Germany we can find interesting examples in the Ruhr Area with a lot of industrial brownfields or in cities as Freiburg with big former military sites. In the Ruhr Area the International Building Exhibition from 1989 to 1999 was established. One of the central themes was housing, including the refurbishment of old worker settlements as garden city types and the construction of several thousand flats on brownfield sites. The following examples could be showed:

Bochum, Zeche Holland: Mulitfamily housing on a former mining site sourrounded by green and water.

Dortmund, Tremoniapark: Singlefamily housing around a park on a former industrial site.

Freiburg VaubanViertel: housing in different structures with a lot of green and good environmental concepts (e.g. energy)

4.2 Spaces for children's nature experience

This type of green brownfield combines two aspects. The genuine development of nature and the free, wild play of children. Children, often raised in an artificial environment, lose the contact with nature and do not experience the feeling of "wilderness". In these "Naturerfahrungsräume" they can learn the identification

with nature, the self determined play and some knowledge about ecology. Especially for schools such areas (1-2 ha=2,5-5 acres) are important places as outside classrooms. A research study is recently done to evaluate the positive influence of these spaces for children's health and attitudes.

Examples of playgrounds for children; paved unattractive environment and green spaces for free, creative planning.

Own source (Source: Tschäppeler, S. et al.: 2007)

4.3 Temporary uses with citizens

Especially the cities of Germany's East have to deal with a declining population, the moving away of people and remaining areas with little development chance. Therefore "temporary uses" for these building plots and sites have become an important phenomenon in city development. Temporary uses today are the product of structural changes in the economy. They are a strategy in a transformation process, they must be developed together with the citizens and they must be integrated in the urban planning remit.

Berlin and Leipzig present important examples of these transformation strategies. Berlin has about 1000 building plots with 170 ha in the inner city and is a pioneer in the creative development of these properties.

Leipzig as a member of the program " Urban Redevelopment Scheme in former East Germany" took part in the research study "Temporary Uses and new Open Spaces".

Leipzig lost 20% of its population and has a surplus of 60.000 flats. Both cities are very progressive in ideas and concepts for the empty space development and follow a strategy which has the participation of citizen as an objective.

The range of development projects is extremely wide, e.g.: New parks and urban forests in large residential areas; summer-gardens with the neighbours; coloured gardens, asylum plant flowers and vegetable; gardens for disabled people; school gardens; playgrounds for children; urban farms for urban children; BMX spontan, a sporting area for bikers; SANDSATION, sculpture park; nature conservation projects with livestock.

There are numerous projects. The common idea is the toleration of the owner of a temporary use, often the citizens' initiative and the support by the city. Often these projects are realized with a very low budget.(Ziegler-Hennings, Chr.: 2007)

5 INCREASING VALUE THROUGH GREEN SPACE (CASE STUDY FFM)

Increase of property and real estate value, is that possible?

At present, less attention has been paid to urban open spaces in every day political and administrative life. This has led to a severe neglect of these amenities. As a consequence, they do not only lose their positive effects on the environment in terms of ecosystem services to a great extent, but might also actually be partly responsible for an accelerating decay of certain parts of cities because unkempt, littered and run down parks are often associated with crime and under-privileged neighbourhoods by the public (Mahler 1998, Urban Park Forum 1999). The location of a site is the main factor for fixing property and real estate value, the factor open space is part of the location factor.

The economic effects of (urban) open space, as described in chapter 2, need to be pointed out, especially for developers of cities. Consequently, for a rational debate on the importance of (urban) open spaces and their

economic effects, it is important to find out more about which kinds of open spaces are appreciated by the public and which economic benefits actually result from them. This is the main goal of a research study on behalf of the GALK DST (German Federation of Park and Recreation Administration)) named "The Effect of Urban Open and Green Spaces on the Value of Properties and Real Estates". Against the background of the completed research study (at the University of Berlin and the Austrian Research Centers, Vienna) as well as the purpose of the project, to create a representative, German wide data basis for the evaluation of property and real estate values, is one aim of the project, to enlarge the data basis of about 15 cities about 10 more cities in collaboration with the already concerned cities of the former study. Afterwards the complete dataset has to be statistically evaluated and produced in a report. Additionally there will be a city specific analysis of some cities.

Statistical analyses of land value data from European Cities based on random samples reveal new information regarding economic benefits of open spaces (LUTHER 2000; LUTHER & GRUEHN 2001; LUTHER & GRUEHN 2002; LUTHER, GRUEHN & KENNEWEG 2002; GRUEHN 2004, GRUEHN 2006; HOFFMANN, GRUEHN 2010).

The aim of the research is:

- to discover the relationship between land value and the provision and quality of open spaces as well as
- to verify the value-increasing effects of urban open spaces by means of statistical methods.

The central hypothesis is:

Open spaces, or, respectively open space related criteria, have a positive influence on land value.

The research method is a statistical analysis of collected data, which describes on the one hand the open space itself and on the other hand the street sections, which are defined at the beginning as an average and stratified sample.

Data acquisition comprises two types of data, dependent variables (e.g. land values) and independent variables (open space related variables referring to street sections or open spaces in the vicinity of the examined plots). Additionally control variables (urban density, urban development restrictions or allowances) were included to eliminate interpretation errors (see figure below).

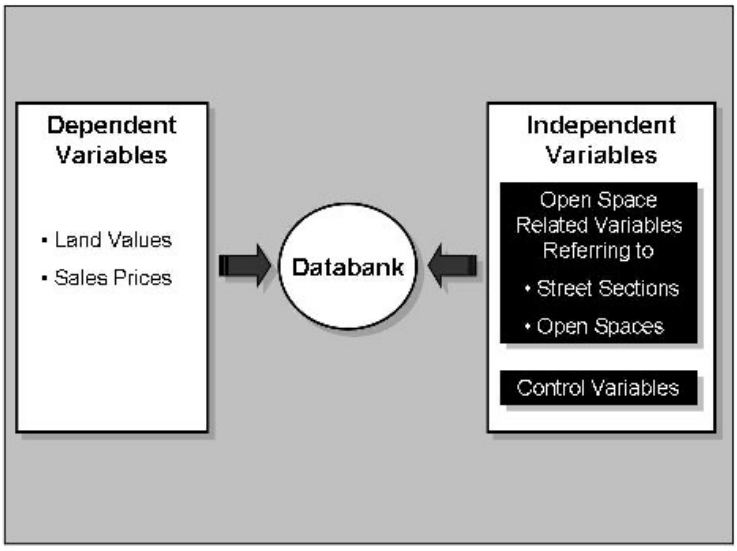

Fig. 5: Data Acquisition

The identified street sections are the locations of examination (US 1 and US 2 in the figure), 150 in each participating city. To identify green spaces relevant for the analysis we surround the locations with 500, 1000 and 1500 meter buffers. The following list gives some examples of open space related criteria which is collected and analysed in this study:

- Distance (of the sample elements) to neighbourhood open spaces,
- number of listed gardens within a radius of 500 m,

- lack of local city parks in specific urban environments,
- vicinity to open spaces and inshore waters,
- number and size of nature reserve areas or areas of great natural value in the vicinity of the sample,
- visual street quality,
- urban fabric.

Hypotheses were formulated which stated that each of the above mentioned criteria has a positive effect upon land value. Whether or not the hypotheses were correct was determined through the application of specific statistical tests on the data collected. A confidence level of at least 95 % (i. e. a p-value $\leq$ significance level α ($\alpha = 0.05$)) is necessary to accept a hypothesis. If accepted under this condition, there is a significant connection between the sample and the population from which the sample was drawn. In other words, there is a significant effect upon land value of the criteria examined.

The ANOVA (analysis of variance) was the main tool for the statistical analysis. It is a method which helps to detect the effect of certain variables on one or several other variables (BACKHAUS et al. 1996). Its purpose within the survey was to examine if there is a statistically significant effect of the independent variables (location criteria) on the dependent variable (land value). If so, additional statements regarding the level of the influence can be derived. Thus, it is possible to distinguish and to weigh the individual location criteria with respect to their importance as regards land value.

In addition to the ANOVA, other test statistics were applied, depending on the quality of data available and on the specific questions to be researched: the t-Test and nonparametric procedures, like e. g. the KRUSKAL-WALLIS-H-Test and the U-Test of MANN and WHITNEY.

The case study presented in this paper is placed in Frankfurt Main, Germany. Additional to the case study, which is under process, we will present results of the former study, carried out by Prof. Gruehn, from Berlin and Malomoe. Pre-analyses have shown that there is a missing of high and very high quality green areas within the boarder.

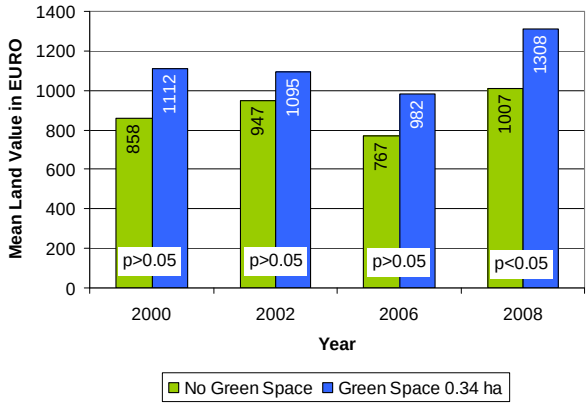

Fig. 6: Effect of the existence or not existence of green space on the mean land value

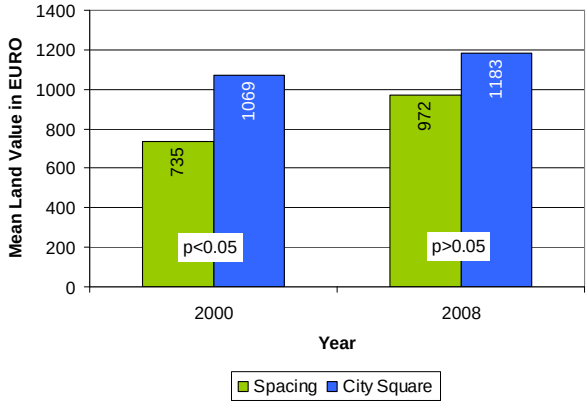

Fig. 7: Effect of spacing areas and city squares on the mean land value

As you can see in the figure above (6) effect of green space in cases of existence or not existence within a 100m radius around the locations of examination can be shown from 2000 to 2008 by of the mean value of the land value in the area around the future European Central Bank building. The result of the executed t-Test is that the values for 2008 are significant with $p<0.05$.

As you can see in figure 7, there is a difference in the mean land value between locations of examination with a spacing and those with a (green) city square of high quality related to the intensity of design. The mean difference is significant to a 95 % confidence level (t-Test) for the year 2000. Frankfurt has a very strong real estate market, so that the significance is getting lower in the years 2002, 2006 and 2008.

Also significant results can be shown from Berlin in Germany and Malmoe in Sweden. The data analysis for Berlin revealed that the extent of the sample land values is unambiguously dependent on the distance of the statistical blocks to their next neighbourhood open space. Comparing the means of the different categories, it can be shown that land prices decrease with a growing distance to this open space category (Figure 8). The mean value of the blocks with a distance less than 400 m is about 170 €/m² higher than the mean land value of blocks with a distance more than 400 m. The mean difference is significant to a 99.9 % confidence level (t-Test).

Fig. 8: Effect of the Distance to Neighbourhood Open Spaces on the Mean Land Value in Berlin (t-test)

Also the data analysis revealed that locations with a high density of listed gardens have significantly higher land prices than those with a lower density (Figure 9). If there are at least two listed gardens within the radius examined, then the plots are on average about 370 €/m² more expensive than those without such a feature. The variable ”Number of listed gardens within a radius of 500 m” has an effect of 18.9 %, i. e. the variation of land prices is nearly 20 % dependent of this factor.

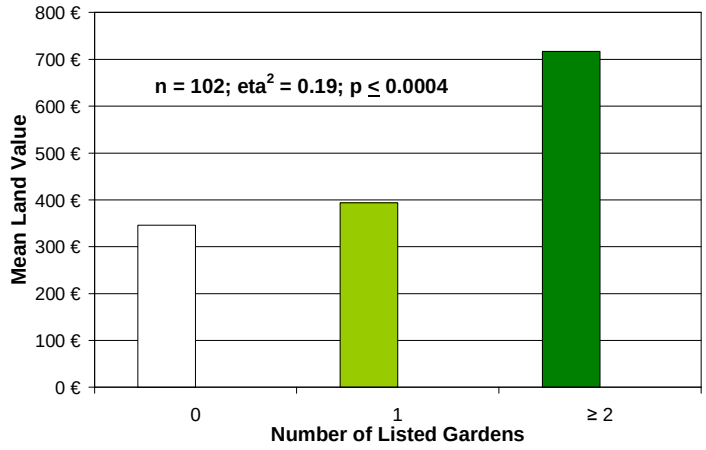

Fig. 9: Effect of Listed Gardens within a Radius of 500 m on the Mean Land Value in Berlin (ANOVA)

Figure 10 points out the effect of local city parks and missing of local city parks respectively, on the land value on residential quarters in Malmoe (Sweden). The data is valid for mixed development zones in the inner city, which are characterized by enclosed block development. Missing of local parks is linked with a significant negative impact on the mean land values in both cases, apartment houses and offices. The absence

of local parks explains 13 % or 22 % respectively, of the total variation of land values in mixed development zones in the inner city of Malmoe. The effect is significant to a 99.9 % confidence level.

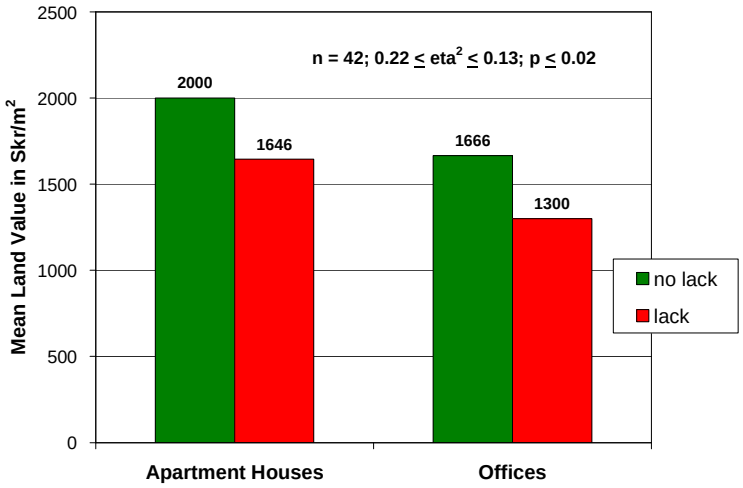

Fig. 10: Effect of Missing of Local City Parks on the Mean Land Value in Residential Quarters in Malmoe/Sweden (ANOVA)

6 CONCLUSION

The results of the described examples and the conducted studies present the importance of green spaces in the urban structure, their meaning for ecological and social quality in the city and their importance for the economic value of properties. The paper gives an overview on the originating of brownfields – urban waste land and the chances and opportunities to use them for improvement of urban environment.

Two specific aspects were regarded more detailed, the importance of the integration of the inhabitants in the reuse process and the meaning of green spaces for the land value. By presenting examples of different German cities, the authors specify these aspects and point out the importance to include them in the urban planning process. As shown through statistical analysis the land value and the prices on the real estate market are dependent on the existence and quality of urban green spaces. The inhabitants recognize very well the quality of their urban environment. The combination of social activities and economic factors occupies an important role in the sustainable urban planning process. The presented way to consider them can be an advice for other cities.

(Tatjana Mrdjenovic, Faculty of Architecture University of Belgrade, Bulevar kralja Aleksandra 73/2, tmrdjenovic@gmail.com)

1 ABSTRACT

The focus of this paper is in reviewing the possibilities of new designed and tested teaching concepts, methods and skills at the Faculty of Architecture Belgrade University (FABU) based on the contemporary theoretical and practical European approaches in the field of sustainable urban transport and mobility and implications for future urban experts in the field of urban development and mobility practice in Serbia.

The importance of knowledge and information is rapidly rising in the knowledge economy especially in cities as nodes of production, processing, exchange and even trade of knowledge. Important role in that process which occurs in cities belongs to the Universities and research institutes, beside many other relevant actors like public authorities, NGO's & CBO's, private companies, civil society.

In the process of Serbia's accession to the EU the whole country is in the process of reform dealing with burdens from the past and aiming towards European values. Legislative as well as capacity building activities are present from the year of 2000 by democratically elected governments and by international NGO's and official governmental organizations (EU commission…).

FABU participates in the FP6 EU funded project 'Sustainable Surface Transport' as one of the partners in the project, disseminating knowledge on sustainable urban transport and mobility.

The project has enormous importance for improvement of all our institutions in the field of clean and sustainable urban transport systems and promotion and participation of Serbia in European Union projects. Benefits of using ELTIS web site is that experts from various fields can expand their knowledge on sustainable urban transport and mobility systems using findings and specific experience from other countries.

With the aim of disseminating knowledge on sustainable urban transport and mobility in Serbia the Faculty of Architecture realized several activities and results on urban transport and mobility issues:

- Promotion of ELTIS web site on seminars, round tables and trainings delivery in Serbia to public sector representatives (ministries, local authorities, urban planning traffic departments), NGO's (bicycle associations), private sector urban design offices.
- Translation of 56 English case studies into Serbian language and 13 Serbian case studies accessible on the ELTIS web site.
- In the education curriculum at the Bachelor level at the Faculty of Architecture new subject ''Mobility in cities'' was established two years ago where students work with realized EU and Serbian case studies on sustainable urban transport and mobility and its implications on urban structure, compare EU & Serbian context and give recommendations in mentioned field in soft aspects for policy issues, urban planning & management concepts, and urban design.

These new teaching concepts and methods designed & conducted by the authors of this paper were tested for 2 semesters and proved to add value to the knowledge and specific expert skills in two direct ways. One was that the increased demand from the students on sustainable design and urban mobility led to the additional subject ''Traffic in cites'' introduced last year. Another direct result was visible in the Urban Design Projects on Bachelor and Master level of studies where students applied new knowledge and skills on aspects of urban design and planning of the development of cities and reaching liveable and healthy cities for all users in accordance with principles of sustainable mobility concepts.

The paper explores and discuses new knowledge from the comparison of European and Serbian context and its applicability in the future urban development and mobility education and practice in Serbia.

2 INTRODUCTION

Aware of necessity of significant changes in Serbia, we are nowadays dealing with the problem of defining how to adjust our existing institutional and public authority capacities and their activities to the strategic development model demands. The major problems are appearing from incompatibility of existing

institutional and governmental capacities and their activities, established 50 years ago, in comparison to the organizational demands derived from new modern model of governance and management. Changes that are to be made mean fundamental reorganization of public sector.

In the process of Serbia's accession to the EU the whole country is in the process of reform dealing with burdens from the past and aiming towards European values. Legislative as well as capacity building activities are present from the year of 2000 by democratically elected governments and by international NGO's and official governmental organizations (EU commission…).

3 CHALLENGES FOR FACULTY OF ARCHITECTURE'S PARTICIPATION IN EU FUNDED PROJECTS

Under the coordination of prominent Austrian scientific research association Forschungsgesellschaft Mobilität gemeinnützige GmbH FGM AMOR Austrian Mobility Research (AMOR) Faculty of Architecture University of Belgrade (FABU) participates as a partner in the FP6 EU funded project 'Sustainable Surface Transport' from the year of 2005.

The Project aims to achieve international cooperation and review the possibilities of application of the results achieved so far within the EU FP6 projects in countries that have recently become EU members or countries that are its potential members. Participation of FABU in the Project is of the great importance, since it was the first time that one of the countries from the Western Balkans, potential EU members was included in the EU FP6 program.

European Union (EU) and European Commission have made great efforts for a long time in promoting sustainable urban transport. One of the ways that is the part of the Project is European Local Transport Information System (ELTIS) – an initiative of the European Commission's Directorate General for Energy and Transport. ELTIS is website that provides access to the best scientific and practical results and research materials for training and learning in the field of sustainable transport systems. The aim of ELTIS is to provide information and support a practical transfer of knowledge and exchange of experience in the field of urban and regional transport in Europe.

The Project's primary objectives are:

- to make easier to use and allow users easy access to all relevant information (news, files, materials)
- to increase the number of available examples, materials, and translations and to include new content and topics;
- to increase the number of users through the construction of ''brand'' ELTIS Web site and allow a professional Marketing (goal is that ELTIS website become ''Google''search engine in the field of transport);
- to focus attention to the new EU countries and countries in the EU accession process through a system of expert training and workshops, translation of the most important examples of the languages of these countries and to offer active user support;
- to offer non-traditional ways of knowledge dissemination.

Through the ELTIS website it is possible at this moment to directly establish more than 150,000 contacts through various user's network that ensures the project's broad and far-reaching impact even after completion (expected in april 2010). It has been expected in 2005 and has been realized so far that inclusion of non-European partner network (Eastern European, Asian and Latin American) will enable new initiatives for the successful exchange of knowledge, and Europe on the other side will be able to promote its own approach to issues of sustainable urban transport systems on a global level and contribute to global dialogue.

The expected result of the implementation of the Project is increased level of knowledge and practical use of research results developed in the enlarged EU. It should be achieved through expanded ELTIS service, specific activities in the field of education and training of professionals and focused on development initiatives.

In that respect, FABU prepared and realized several activities within the Project with direct showing benefits to relevant stakeholders such as policy and decision makers, politicians, heads of urban management departments, public transport operators, practitioners in the field, university staff, researchers, students:

- Access to the Information network users through ELTIS web service;
- local representation of realized and potential projects (both research and practical) in the field of sustainable transport systems at European and world level;
- involvement in a series of workshops on topics of ecological and sustainable urban transport system that FABU will organize and implement;
- access to brochures and other relevant research and practical materials specifically oriented to the problems of the partner countries (in English and Serbian language);
- the possibility of inclusion in training courses for the training of experts.

The project has enormous importance for the capacity building activities of our institutions and organizations in the field of clean and sustainable urban transport systems and promotion and participation of Serbia in European Union projects.

Benefits of using ELTIS web site is that experts from various fields can expand their knowledge on sustainable urban transport and mobility systems using findings and specific experience from other countries.

With the aim of disseminating knowledge on sustainable urban transport and mobility in Serbia the Faculty of Architecture realized several activities and results on urban transport and mobility issues:

- Promotion of ELTIS web site on seminars, round tables and trainings delivery in Serbia to public sector representatives (ministries, local authorities, urban planning traffic departments), NGO's (bicycle associations), private sector urban design offices...
- Translation of 56 English case studies into Serbian language and 13 Serbian case studies accessible on the ELTIS web site.
- In the education curriculum at the Bachelor level at the Faculty of Architecture new subject ''Mobility in cities'' was established two years ago where students work with realized EU and Serbian case studies on sustainable urban transport and mobility and its implications on urban structure, compare EU & Serbian context and give recommendations in mentioned field in soft aspects for policy issues, urban planning & management concepts, and urban design.

4 REFORM OF HIGHER EDUCATION AT THE FACULTY OF ARCHITECTURE BELGRADE UNIVERSITY (FABU) AND RELATION TO EU PROJECT

University of Belgrade exists from 1846. Throughout the history it has changed several times its organizational form, but on the other hand many of the principles are rooted deep and it is almost a rule that change is something that happens very slowly in academic world.

Until the year of 2005 organizational form and structure of FABU dated from after the World War Two with cathedras as basic organizational units with different subjects within them. There were several attempts of radical change of educational plan and program and therefore organizational structure of FABU, but more or less they remained incremental or temporary.

Most of the proposed changes in the past failed due to several reasons, but most important was the resistance of people to change due to established norms and values within character of organizational structure mentioned above. Another reason was that there were not real pressure from outside environment that would call for fundamental change, especially in "well designed and planned system as Socialist centrally driven system was".

Things have changed with the political and overall changes in Serbian society at the end of '90s. Shifts from centrally planned to transitional economy in Serbia and attempts to follow European integration processes have had major impact on the FABU. Most important inputs are: 1) Bologna declaration, 2) Legislative change in Higher education in Serbia (new Law on Education from 2005) and 3) obvious need for improvement of Educational Processes and Programs at the Faculty.

Finally, Bologna declaration brought the change in 2005 both in organizational system of the Faculty in terms of:

- 1. three years of basic, Bachelors studies and two years of Master studies;

- 2. cathedra based organizational arrangement to independent subjects and their relations due to need of Educational programs;

Those changes created the platform in which new elective subjects could be established and included in the Faculty curriculum with the cooperation with other institutes or within national or international projects.

5 NEW CONTEMPORARY MOBILITY ISSUES AND CONCEPTS FOR FUTURE URBAN DESIGNERS AND ARCHITECTS

Education on the subject ''Mobility in cities'' is directed to explore contemporary aspects of multimodal transport in urban areas in order to achieve sustainable development of urban areas. Education aims to reach the outcome (product, result, effect) and the process (action plan, working method, route, activities). The goal is that students gain a basic understanding of modern management concepts in transportation systems and mobility in relation to land use in urban areas. It is also important that they understand the role of architects and urban designers and planners in these processes along with other experts and stakeholders such as public authorities representatives, local communities and their needs, private sector interests, etc.

Students acquire knowledge on methods, techniques and skills on organization of sustainable urban transport systems in relation to land use in order to apply their knowledge and learn what kind of implications will decisions based on principles of sustainable transport will have on the spatial organization.

The main goal in the teaching process is dissemination of aspects of design and planning of urban structure development in order to achieve higher levels of quality of life in urban areas in accordance with the principles of sustainable urban transportation systems.

Subject outcomes are closely related to the problems of urban design and planning and students applied new knowledge on the subject Urban Design Project on the same semester and in the Bachelor Design Project.

The basic knowledge and learning outcomes that students gain on the subject are:

- Understand key contemporary disciplinary issues related to enabling multimodality problems of transport and mobility of people in urban areas through the review of the basic assumptions in the field of sustainable transport: mobility management, parking management, relation of land use planning with the sustainable transport, aspects of safety and environmental protection.
- methods of mobility management, parking management and relation of land use planning with the sustainable transport
- Practical knowledge of the principles of urban design in accordance with the requirements of high mobility and sustainable transport in the city.

This theoretical and practical knowledge increased the competence of students in solving problems of urban design and planning in accordance with the principles of sustainable transport systems in the city and skills to collaborate with experts in the field of integrated transport in solving urban problems in a competent way.

Method of teaching that were used during the course were divided into two main blocks:

- Block of interactive lectures divided into four groups of basic trainings in the field of relation of land use planning with the sustainable transport, mobility management and transport, parking management, and safety and environmental protection;
- Block of exercises divided into two parts where students work on:
    - 1. The study of literature and analysis and comparison of implemented cases from the European Union and Serbia from one of these areas of their choice;
    - 2. Thematic exercise: analysis of selected specific real urban situation and forming conceptual proposal and solutions from one of these areas of their choice;
- Two presentations of added knowledge on key issues based on the results of implemented: 1) research, analysis and comparison of cases, and 2) the proposed solutions;

Final research report include findings from the research analysis and comparison of EU and Serbian cases, as well as guidelines for soft policy measures in the field of urban design and planning in accordance with the principles of sustainable transport in our community.

Students deal with important questions such as: What is missing in Serbia so that similar principles / decisions / actions like in EU can be applied in this context (for example: lack of integrated policies, transport awareness campaigns, institutional resources and know-how, the will to change or learn, the participation of relevant stakeholders, guidelines, laws, monitoring results, etc.)? What are the benefits in Serbia or what is better done than in the European Union, or what the pitfalls are? Further recommendations are given as the series of future and next steps in capacity building, travel awareness, stakeholders participation, campaigns targeted towards end – users.

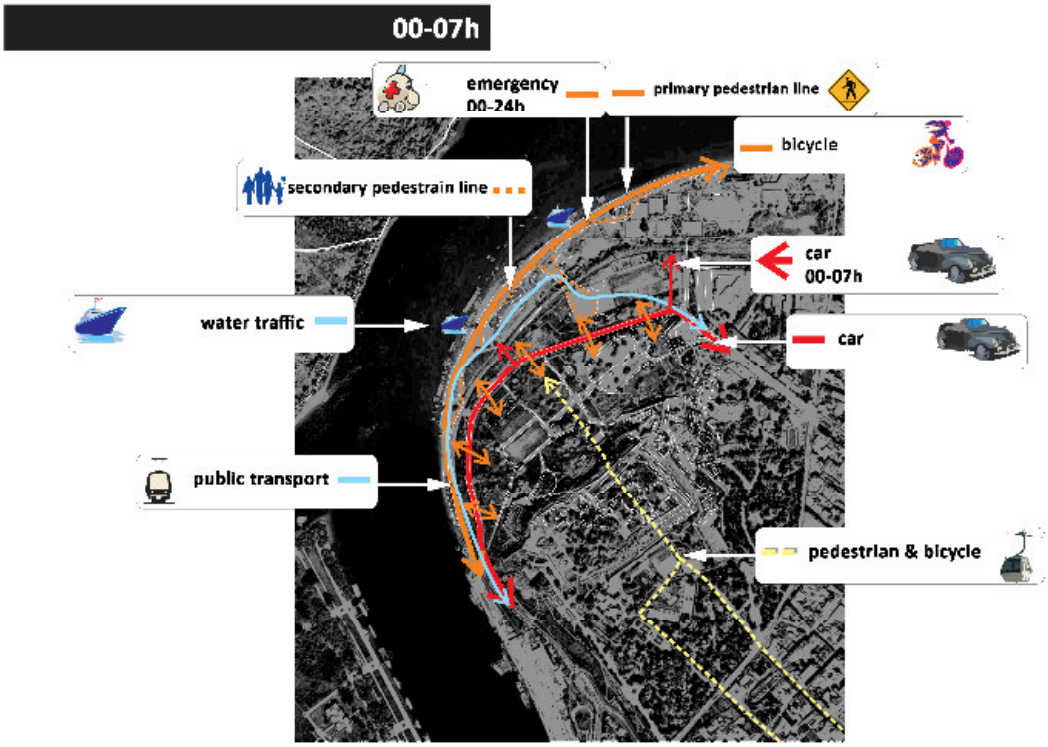

Fig. 1: Application of knowledge from ‘’Mobility in cities’’ on student’s Master Urban Design Project (students Jovana Pavić and Stefan Drašković)

6 CONCLUSIONS AND EXPECTED IMPLICATIONS

Following criteria that the teachers and the authors of this paper included in the evaluation of results and findings are important both for the improvement of the subject ‘’Mobility in cities’’ in the education process and for the specific knowledge and skills in the field of sustainable transport for future urban designers and architects.

- ‘’emotional perspective’’ in order to support ideas and concepts for clean and sustainable urban transport like e-mail gimmicks, cartoons and illustrations;
- acceptance of professional English language terms with the outcome of reading and understanding English literature in the field of sustainable transport and sharing knowledge and experience with the global community;
- flexible process - students attitudes / stakeholders in real arena towards new topics (student’s identification of specific Serbian cases that are further presented, discussed and approved both by teachers and other students);
- identification due to flexible process that creates sense of belonging within the group and forming of identity trough the Case (for example – students often tend to call students upon specific cases they have elaborated – ‘’Drunken drivers’’ for special service for drunk car drivers that want to safely be driven home by motor bikers);
- non-traditional ways of information and dissemination trough visual products from ELTIS such as brochures, website, presentations;

- attendance on local conferences and seminars in Serbia and enlargement of knowledge with relevant stakeholders from the region and neighbouring Balkan Peninsula countries;
- interactive workshops with guest lecturers from public enterprises in the field of sustainable transport, representatives of NGO's and CBO's;
- 24/7 on line support and e-mail communication with students / or end-users in ''real urban arena'' up to the creation of mobility centre for information; and,
- student's point of view on new gained knowledge and skills and general satisfaction related to expectations from the beginning of the subject period (beside general evaluation at the Faculty level).

Planning for Health Amelioration: Analyzing Mumbai's Urbanization Patterns

Amitabh Verma

(Mr. Amitabh Verma, University of Georgia, Athens, GA 30602, USA, averma@uga.edu)

1 ABSTRACT

Indian urbanization is characterized by multiple extenuating circumstances which forestall the emergence of ideal communities within cities. Issues such as overpopulation, social fragmentation and environmental degradation which are symptomatic of developing countries impact cities negatively, compromising quality of life. The urgent necessity to address basic needs for a growing population is consistently prioritized over the planning of cohesive, organized and healthful communities. Such unregulated urbanization poses challenges to the creation of viable, sustainable communities, in addition to generating circumstances of significantly compromised public health. This paper offers an empirical evaluation of contemporary developmental patterns in Mumbai (predicted to become the world's second-largest city by 2050 with 26 million residents) as a case study with critical implications for urbanization in other Indian cities. It analyzes demonstrated developmental trends, identifying inherent drawbacks as well as positive parameters evident in recent growth. The study posits that the urban environment can be ameliorated by comprehensive planning to moderate the impact of social, cultural and economic disadvantages, arguing that planning is essential for future communities representing the desired ideals of aesthetic form, social cohesion, equitable social engagement and improved health.

2 URBANIZATION IN INDIA

Global urbanization manifests itself at an accelerated rate in the developing world. This phenomenon is especially pronounced in India[1], where high rates of population growth and the urban/rural developmental imbalance (partly a legacy of colonialism) have precipitated a sustained, large-scale migration to larger cities by populations seeking economic opportunity. This unprecedented and unregulated over-urbanization (Datta 2006, 1) exceeds the absorption capacity of cities and compromises their identity, character and functionality. It degrades the quality of life and deprives the population of advantages which the city should ideally provide. Although the quality of life in India's cities is perceived as superior to that in towns and villages, this superiority is essentially materialistic – better employment opportunities, greater income potential and improved amenities exist, but social cohesion, aesthetic environments, meaningful community participation and nature-derived benefits are relatively lacking. Characteristic problems of Indian cities include overpopulation, poverty, substandard education, deteriorating environmental quality and impacted urban health[2] (WHO 2007).

Fig. 1: Streetscape in historic Mumbai

Fig. 2: Public plaza edged with distinctive architecture

[1] World population is estimated to be 70% urban by 2050, with growth mostly concentrated in Asia, Africa and Latin America. India and China together will account for 35% of this increase. (UNPD 2007)

[2] Major environmental health risks (caused partly by development without environmental safeguards) account for nearly 20% of India's total disease burden.

This situation is exemplified in Mumbai, India's fastest growing city and the fourth-most populous in the world[3]. Conceived as the British colonial city of Bombay, its sophisticated historic core with elegant architecture, street hierarchy, public spaces, monuments and vibrant landscape creates an urban map that is the most expressive and experientially-rich part of the city (Figs. 1, 2). Recent growth beyond this core, however, has not attained a commensurate level of coherence. The urgent need to provide shelter, transportation and employment to a steady influx of migrants compels development to be largely housing and road construction rather than the building of coordinated, environmentally-responsible communities inclusive of other requisite components – public spaces, gardens, marketplaces and civic monuments. Consequently, most new neighborhoods are essentially housing districts devoid of social identity or unity. This reactive approach has other consequences as well – it precludes the conservation of environmental, social, cultural and historical resources in the process of constructing infrastructure, and marginalizes nature, creating ecologically-unsustainable environments which compromise resident health.

3 URBANIZATION AND CONSEQUENCES FOR PUBLIC HEALTH

While cities offer access to better medical facilities, public health can be negatively impacted by certain urban conditions such as overcrowding, improper sanitation, inadequate drinking water, pollution, etc. which increase incidence of disease (Aicher 1998, 43). Urbanization also compels a reinterpretation of traditional patterns of living, deemphasizing or eliminating conventional healthy practices, with the import of these modifications often unrecognized by the general population. The situation is exacerbated by a widespread lack of awareness and prevalent misinformation about health (for instance, Indian culture has traditionally assigned value to obesity as a sign of prosperity). Three major derivatives of contemporary urbanization which adversely impact health and which pertain to physical planning are enhanced city size, individual-level adaptation, and societal trends, as described below:

- Magnified Constructed Scale

  The physical scale of Mumbai involves distances which are too large to negotiate on foot for accomplishing daily tasks, a fact that encourages private automobile ownership and eliminates opportunities for physical exercise. Personal transportation is also preferred, both as a status symbol and as a consequence of the overburdened public transit system.

- Redefined Recreation

  An altered perception of 'recreation' has led to a preference for passive, sedentary activities (watching television) over outdoor activities (walking in the park or to the market). The increasing prevalence of individual-centric lifestyles, limited time for leisure, curtailed social networking and higher levels of isolation and stress as a consequence of "urban disruption" (Fullilove 2006, 187) further reinforce this inclination.

- Cultural Value Shift

  Western modes of behavior (conflated with progress) are being adopted due to the prestige assigned to westernization in the public perception. The growing preference of the urban middle-class for malls, fast food, processed or pre-packaged meals and synthetic beverages[4] (Cunningham 2006) is rationalized by convenience and efficiency and affects health negatively[5]. At the same time, consumption of healthy foods – fruits, vegetables and pulses – is well below accepted standards nationwide[6] (Mudur 2003).

In recent years, social scientists and medical professionals have mapped a steady increase in health issues afflicting urban residents. As linkages between urbanization and health concerns are increasingly documented and verified (Agrawal 2002; Datta 2006; IIPS & Macro International 2007) the effectiveness of city planning as an instrument to improve health is actively promoted (Jackson 2003; Sengupta undated; Rice and Rasmussen 1992), creating opportunities for city planners and urban designers to resolve this problem through comprehensive planning.

[3] Predicted to become the second-most populous by 2050 with 26 million people. (UNPD 2007)
[4] Cunningham correctly identifies obesity in India as largely a disease of the urban middle-class.
[5] According to The National Family Health Survey, obesity is most common "in urban areas, among the well-educated and those in the highest wealth quintile."
[6] Average daily consumption of fruits and vegetables is 150 g/person, instead of the recommended 400g.

4 PLANNING AS PRESCRIPTION

Can physical planning offer an appropriate paradigm for future development in Mumbai and similar communities? While the value of planning for the creation and sustenance of communities has been long recognized in the western world and in developed countries, practical and logistical conditions have precluded a comparable view of planning in India. It can be argued, however, that the detrimental circumstances in which Indian cities must exist and thrive necessitates a stronger emphasis on the inclusion of planning in the development process. Indeed, there have been historical attempts at planned communities with mixed results, including in Mumbai (Heitzman 2008). The ultimate objective – the creation of human-scaled communities which are aesthetically, functionally and socially rich, environmentally-responsible and rooted in their milieu – is universally relevant and as applicable to the Indian condition as to any other place. These considerations are reflected in historical Indian settlement patterns which incorporated walkable streets, contextualized architecture, and valued social spaces. These characteristics, although generally rejected by current development in India, must be acknowledged (and retained) as vital components of the city. By reinforcing their intrinsic value, planning can create real places that eschew the placeless, soulless and generic appearance which characterizes so many cities in the developing world.

The following narrative locates the core values of planning in the context of Mumbai's existing built environment and physical construction, classified as Positive Attributive Factors (substantive assets which actively contribute to the vitality of the city) or Inadequate Desirable Factors (vital, non-negotiable components of the city which are currently absent).

4.1 Positive Attributive Factors

- Pedestrian Focus

  Emphasis on environments which are primarily navigated on foot finds resonance in Mumbai, which is built on a scale amenable to pedestrian movement. This derives both from traditional spatial arrangement of private, public and civic functions as well as the limited integration of the automobile, as a large majority is unable to afford private transportation. This vital component of viability, although omnipresent in India, unfortunately lacks comfortable, safe and pleasant streetscapes to accommodate it. (Fig. 3) Further, the traffic model of a hierarchical network segregating diverse users has not been implemented. Instead, street width is determined by space availability and not by function, design or planting character. All users – from pedestrians to trucks – are compelled to negotiate the streets simultaneously, leading to constant conflict. (Fig. 4)

Fig. 3: Compromised pedestrian convenience, Fig. 4: Pedestrian safety jeopardized by traffic

- Built Diversity

  Complexity and variety exist on multiple levels in Mumbai. A compact, high-density building pattern (Fig. 5) results from escalating real estate prices, large population and rapid growth. The perpetuation of traditional social organization has created neighborhoods peopled by intermingling ethnic, linguistic, religious and economic groups. This diversity extends also to gender, age and education, etc. Although populations in larger cities often tend to coalesce based on levels of affluence, this trend still remains a strong determinant of heterogeneity. Housing similarly manifests

a spectrum of residential options within each neighborhood, ranging from small, affordable units to larger, expensive accommodations, reflecting diverse economic levels, family sizes and preferences.

Fig. 5: Typical high-density, high-rise housing

4.2 Inadequate Desirable Factors

- Contextual Architecture and Landscape Architecture

  Much of Mumbai's architecture reads as an incoherent, repetitive agglomeration of negligible aesthetic value. (Fig. 6, 7) This is true for individual buildings as well as their collective composition. Creative visual expression is largely proscribed by cost, as is continued maintenance, thus accentuating the widespread architectural non-distinction and disrepair. The generic, monotonous uniformity and absence of referential natural features or iconic landmarks fail to create an "identifiable neighborhood" (Alexander et al. 1977, 80).

Fig. 6: Unremarkable, visually unappealing architecture

Fig. 7: Poorly maintained buildings

  The landscape, when not absent altogether, is an ineffective design component, included more as a concession to building codes than for any real contribution to the environment or to the lives of the residents. (Figs. 8, 9) This superficial 'landscape' produces nothing other than a minor enhancement of the aesthetics of the built environment.

- Civic Institutions and Public Spaces

  Mumbai's neighborhoods exhibit no cohesive organizational pattern, epicenter or focus for their spatial arrangement. Historical centers of organization – palaces, temples or public squares – have not been replaced by corresponding democratic emblems for structuring neighborhood form and identity. Civic architecture, shared communal spaces and monuments are not employed in the formation of the community. That role has been tragically assumed by malls which, by virtue of their locations, sizes and distinctive architecture, have become the new locational markers. (Fig. 10)

Fig. 8 & 9: Installed landscapes are perfunctory and irrelevant

- Sustainability and Ecological Responsibility

  The collective environmental impact of Mumbai's population is severe, and recent climate change necessitates the integration of ecological stewardship as an essential component of future planning. As natural conservation is presently not a component of urban planning, natural systems and resources are afforded little protection in the course of development. The implications of construction which ignores topography and natural processes can be catastrophic, as witnessed in the devastating floods of 2005 which paralyzed the city and caused almost 900 deaths[7]. (Government of Maharashtra undated).

Fig. 10: The mall is the new civic landmark

[7] The flooding was partly blamed on the interruption of natural drainage channels, and on garbage (including plastic bags) which is thought to have clogged drainage systems.

Fig. 11: Unprotected, abused creek used as drain

Fig. 12: Garbage covered island in the creek

5 CONCLUSION

While the value of planning, urban design and the influence of a positive built environment on communal behavior are well documented in the western world (Lynch 1960; Alexander et. al. 1977; Whyte 1980), India's developmental history does not reflect a similarly extensive theoretical or implementational foundation for its cities. Although historical instances of planned communities exist, contemporary development is forced to marginalize the time, resources and effort necessary for planning in order to deal with other exigent issues of human necessity, such as housing and employment. Consequently, the form, function and ideological identity of its cities fail to provide citizens with the idealized environments they deserve. The consequences of such environments reflect broader aesthetic, social and functional inadequacies, as well as secondary concerns such as impaired public health.

Many health issues and their deleterious effects which characterize Indian urbanization today can be remedied in communities that integrate aspects of physical wellness in their design. Aesthetically pleasing, socially enriched and environmentally responsible neighborhoods can foster greater participation of the individual with the larger society in ways that nurture physical and psychological health. The current approach which produces mere housing clusters must be replaced with a holistic philosophy that prioritizes both tangible opportunities for recreation (gardens, streets, plazas) and intangible attributes (beauty, comfort, convenience). The provision of destinations for communal interaction and social reinforcement can elevate the standard of fitness within the community with minimal effort on the part of the residents.

As the above narrative demonstrates, the relevance of universal objectives of planning is strengthened by its dual emphasis on pedestrian-oriented design and the neighborhood as the operational unit of urbanization. Walkability is a fundamental characteristic of the Indian city, and its formalization as the essential determinant of city form will incorporate a healthy dimension in the routine experience of daily living. Furthermore, well-designed neighborhoods will allow inhabitants to construct intimate relationships with their surrounding environment, social spaces and neighbors. Individuals are more likely to interact with the exterior, public realm (thus engaging in healthful behavior) if they believe themselves to be stakeholders in their surrounding environment. Indeed, planning at this local scale may be the only pragmatic approach for megacities such as Mumbai, which physically and psychologically transcend conventional conceptions of cities.

The achievement of the goals of planning in India will be facilitated by the human component vital for sustaining a city and manifested in density, diversity, mixed-uses and social complexity. Built for, and peopled by, large pedestrian populations, cities in India are replete with the primary component that makes urbanism successful. It is this fact that has eventually transformed Le Corbusier's Modernist plan for Chandigarh into a thriving city, in spite of its complete disregard for cultural, geographical and environmental context (Verma 1994). The emergence of optimal communities has been prevented by the absence of a comprehensive organizational structure for this human resource, but the implementation of an appropriate framework and planning philosophy can result in cities which accomplish the goals of being functional, socially and aesthetically pleasing, contextually relevant and environmentally sustainable.

Ultimately, planning's most significant contribution (and one which also directly influences health) would be to heighten awareness of the ecological crisis, worsening continuously, which recent history has precipitated. The necessity to protect, conserve and treasure natural resources must inform any planning philosophy that seeks to create durable cities, and be incorporated in administrative policy. This awareness is critical in view of the global future – as natural resources diminish and populations grow, sustainability and ecological responsibility become the only options available. At this stage, we do not have the luxury of pretending we are not in trouble.

Planning healthy cities - the role of markets in urban life

Kravalik Zsuzsanna

(Ms Kravalik Zsuzsanna, Eötvös Lóránd University, Budapest, 1053 Múzeum krt 13. kravalik@gmail.com)

1 ABSTRACT

Liveability of urban areas depends on the quality of common urban places, on the places where people unintentionally meet with their neighbours. Thus it is the quality of life in the neighbourhoods and within it the routines of our everyday life, which defines the quality of our urban lives. Food shopping is a necessary activity of our urban lives and we spend more and more time on the urban places for shopping. The places of shopping, the food malls and markets are taking an important position in our everyday life in the city. The importance of markets is visible from the many markets which have been redeveloped and being under reconstruction in the past years in Budapest. But how can we foster good quality urban places from markets? What are the architectural considerations for creating a welcoming community public space and what other urban development arguments lead the work of our urban planners, these are the questions, my paper tries to unfold. Therefore the question of my research is not about the architectural quality of the buildings but rather the quality of life created in these market places. The research is based on the qualitative interviews with urban planners and architects active in Budapest in the last 5-6 years in reconstructing urban public spaces in and around market halls.

2 INTRODUCTION

„Our final conclusion is that going to market gives you pleasure, even for people like us, busy intellectuals, if not other time than on a Saturday morning." (Piackalauz romantikusoknak, 2004)

"More than just public spaces for buying and selling food, public markets are civic spaces – the common ground where citizens and government struggle to define the shared values of the community. The public market is society's conscience – the place where we can see, hear, taste and smell whether or not government is doing its job." (Tangires, 2005)

Markets as urban institutions are praised from all aspect. They are taken for pleasure while at the same time they are praised to be the backbone, the conscience of society arguing that markets are truly democratic places. But what it is in markets which make them so unique and important in the quality of urban life? What is the secret of markets? How can the urban space transform the duty of shopping into a pleasure-seeking experience? In this paper I aim to unfold the physical and architectural characteristics of markets which enable them with that commonly hold idea of democratic quality.

Reflections on market places are even more important for two reasons; people get more conscious about the food they eat and local authorities get more conscious about the markets they run, and evidently there must be some causality between them. Firstly food shopping is becoming an important activity within our public life. We spend more time buying our food, and care more about the quality of our alimentation. "While stores have gotten larger, more pervasive, and less personal, we have sought refute in the old forms of farmers' markets. … All over America, shoppers are showing greater awareness about where and how their food is produced, and demanding closer relations with their suppliers."(Zukin, 2004) Food-consciousness gets into people to search for high quality food, to choose ecologically friendly food, or food from bio agriculture and if possible preferring first hand contacts with farmers. Shopping places are one of the most important public spaces of our time. A good deal of our time we spend in private spheres, in our homes and in our workplaces, offices. Most of the time left in-between the private tasks we spend more time for shopping. Therefore it is important how well they are designed and how much they enable contacts between people or rather they are isolating people.

The second reason why we give more importance to understanding the mechanisms of markets is because there is a strong public interest in market renewal in Budapest in the last few years. There have been several market halls and market areas renewed in Budapest in the last 6-8 years. Bigger market renewals include some of the XIX centure market halls, such as the Central Market hall, Battyhany and Rákóczi market halls, and also renewals with more intense alterations such as Fehérvári úti market hall which encapsulates the market place from the 70s, the market cum housing estate of Garay square, the market attached to Mamut shopping mall, the Fény street market, the Lehel market which today has an average daily 25 000 visitors.

Besides these renovations and renewals there is an even greater upsurge of renewal on the way. Mostly it is in the outer districts of Budapest, where local authorities are restoring the markets. Such is the case in Sashalom, Újpest, Rákosmente, XII district, Zugló and Budafok. We should use the experience of past urban developments and market renewals for the benefit of the new ones. We have to use what is there to be learnt from past experiences in creating good quality urban places through market renewal.

The importance of shopping places in our society and the importance attributed to market renewal by local authorities in Budapest are underlined by the third factor for market renewal. If markets are well designed they are able to transform the necessary activities of shopping into the social activities of meeting, seeing and hearing other people, and thus markets can be an infinite source for social interactions. This observation is underlined by the research performed by PPS: "In a society so often marked by divisions rather than commonalities, an incredible thing happens at markets: people talk to one another. Perhaps it's the informal environment, the shared interest in uncommon and beautiful varieties of fruits and vegetables, or the joyful mood created in bustling markets" (Spitzer et al., 1995)

Activities to be performed in public spaces require different attention for their urban design quality according to Jan Gehl. Gehl has developed a very simple three-fold typology for outdoor activities, by dividing our daily movements in cities into necessary, optional and social activities. He argues that people perform necessary tasks such as shopping regardless of the quality of urban environment. According to him optional activities will take place only if time and space allow it, and social activities are the results of other people in public spaces. "Social activities are all activities that depend on the presence of others in public spaces. They develop in connection with the other activities because people are in the same place, meet, pass by one another, or are merely within view." (Gehl, 1971) If shopping is only treated as a necessary activity, than there is no need to be concerned about its quality and physical characteristics. However if it is to become a thriving urban place: its urban quality is at stake. Social activities are dependent on physical conditions of the urban public space.

"Although the physical framework does not have a direct influence on the quality, content, and intensity of social contacts, architects and planners can affect the possibilities for meeting, seeing, and hearing people – possibilities that both take on a quality of their own and become important as background and starting point for other forms of contacts."(Gehl, 1971)

In this paper I aim to unfold the architectural and design characteristics which make markets so bursting urban places. It has a high importance for future urban development and market revitalisation projects: not only to create places for shopping activities but at the same time to help encourage civic life and social activities around the urban space of markets. The research is based on seven qualitative interviews with architects responsible for the renewal of urban markets in and around Budapest. The interviews were conducted in the summer of 2009 and they lasted about 50-120 minutes. My aim has been to distil the essence of market halls so that future urban renewals will be more aware of the functioning of urban markets as places for social activities, social interactions and thus they will be more readily available in creating quality of life around them.

3 HOW IS A MARKET DIFFERENT FROM A SHOPPING MALL?

3.1 Layout

"The market hall at Battyány square was transformed into a kind of department store, losing its spontaneous, free atmosphere typical of the market; instead of a market, it became a commercial institution. … The overly regulated nature of the building at Fehérvári Road destroyed the entire atmosphere. And now that it has been transformed into a market hall, its character has become even more hybrid. The whole form is fettered hand and foot: it is a market and not a market, a market hall and not a market hall. There is no particular expression in it architecturally, beyond its own practical solutions.(Siegel & Uhl, 2005)

What changed the building so radically at Battyány square market that it forbade us to call it a market? What changes puzzled Szalai at Fehérvári market? Is there a real difference in the organisation of space between open markets and market halls, except that one is covered? In this chapter I will try to find the basic characteristics of markets which distinguish them from other shopping places. From the most spontaneous weekly open markets organised on removable stalls to the traditional architectural design of market halls of Budapest from the turn of the century markets have some common threads, common characteristics, which

enables us to differentiate them from shopping malls or hypermarkets. And if we are able to find the major characteristics of a market, then we might also be able to find out why its atmosphere is so much praised, from where comes that openness which makes them such attractive public spaces.

Markets are invading us through all our senses. “So what is it that makes the market hall and its architecture so special? The market hall affects all our senses, accomplishing something that commercial architecture nowadays rarely does.” (Gran, 2005) They have something to offer to all of our ears, eyes, tastes and fingers: smells, forms, tastes and colours all ready to affect our senses. “It is good to enter into a market because of the smells; one feels the smell of fruits, of vegetables. This compound effect of smells and colours of markets, the condensed presence of fresh goods into my senses which makes it feel good. The market is where 100 different vendors sell the same good, and you get simply crazy not knowing which one to choose, since they all look gorgeous. (Kertész)

A market is a rustic shopping space. The market attracts all our senses. And thus they create a very naturalistic atmosphere. There is something familiar and closeness in markets. The smells, colours, sounds lead us into the world of the market, which is therefore more rustic than other types of shopping places. The smell of tomato together with rotten fruits and the odours of the sour cabbage give a mixture of smell with a touch of human respiration in it too. But interestingly it does not end up being revolting, when there is such penetrating stink in it. This is all very naturalistic. In a shopping mall I cannot feel the smells, since everything is refrigerated, neither the colours since the lighting deceives our eyes.” (Kertész) However it is just as much the design of markets which allows and enhances this sensuality, the fusion of the different smells and sounds and also this makes them distinct. The space within markets treats shops and shoppers differently from the big department stores or hypermarkets.

Market is a shopping space where the shops face outwards into the common open public area. “It is not like I go into the shop, but I just stop in front of it at the counter and shop like that. The shop belongs only to the vendor, at the rear there is the sink and service area, and receives the goods, and have vegetables and empty boxes. I am separated by the counter.” (Rajk) And in this respect there is no different between stalls and shops, between open markets and market halls: the goods divide the zones for vendors and for shoppers in both types. On the contrary in a shopping mall the shops are all inwards-looking, in order to get into contact with the vendors I have to step inside the shop, and thus I disappear from the public area of the mall and from the public eye as well. And thus a shopping mall which would seal off the different vendors into separated shops would allow neither the free flow of smells nor the extent of social activities and the fusion of experiences. Thus there is a very strong and distinguishable element which clearly divides market-type urban spaces from non-market type spaces.

Rows of individual shops where one have to enter would not help comparison shopping and thus would reduce the time of strolling. Once you enter into a shop you made up your mind to buy there something. If you come out empty handed, that means you rejected the shop and would not venture back into it again. Whereas market stalls encourage comparison shopping. And it also has psychological consequences too in relation to my behaviour towards fellow shoppers. While in the private areas of a shop I step into a more delicate and more personal area. In a market the life is going on out in the common space of the market, on the aisles which do not belong to any particular shop owner or vendor.

The aisles within the shops or stalls are neutral grounds, they are not the private spaces of private shops, but they belong to the common area of the market, which allows us to behave more freely “Throughout history, markets have been neutral ground, encouraging people to gather, make connections, discover their similarities, and appreciate their differences” (Spitzer et al., 1995) People will not disappear into the secrecy of small shops only to return with something hidden in their shopping cart, but are out and open about their choices, also about their budgets, about their tastes for other people to look at. The life in the aisles gives a higher level of opportunity for watching people and for this reason markets become places for social activities. In a market I would not offend other people by watching them doing their shopping. Markets are the greatest places for people-watching, and thus for social activities. And the shops merely provide a veil for the life going on among them. It is therefore the general layout of markets which generate this common ground for social activities.

“Best of all, even if you’re by yourself at the farmers’ market, you’re never shopping alone. Unlike in stores, strangers often talk to each other.”(Zukin, 2004) This is what transforms the shopping activity into social

activity: markets through their use of space allow much more encounter between fellow shoppers and does it with a high level of openness: we can see other people to choose, to talk to the vendor which will in turn inspire us to talk to other people too.

Returning to the original question, now it seems easy to respond. It became easy to decide whether a shopping area is a market hall or a shopping mall by studying the stalls: do they face outwards? Thus the market hall at Batthyány square has become a shopping mall, by turning the shops inward, by closing off activities into different small entities. However Fehérvári road market hall maintains its market like atmosphere by the imminent contact of shoppers and goods, by the open layout of shops and stalls, and thus by the social activities it is able to create.

3.2 Density

Besides the layout of the shops there is another factor which attracts even more people on the aisles of markets: the density of shops. “With great distances in the urban plan, there is nothing much to experience outdoors.” (Gehl, 1971) The density of shops is although not as clear cut as the orientation of the stalls but also very important feature of markets. Gehl’s statement is not only true for outdoor streets but also for markets and inner shopping areas. Within markets there is twice as much shop on the same surface area than within shopping malls. The size of shops within a market do not exceed 25 sq meters, while in shopping centres there are around 50-100-200 sq meters. It seems than in Budapest not all local authorities are aware of the choice they have to make between the benefit of intense social activities created by small size shops and the economic considerations of larger floor area shops. “I doubt that they had some kind of background study, since the call is very vague. For every shop size they give 20-50 sq meters, which means, I can make double or half size buildings. It will become the responsibility of the architect how large shops and market building to design.” (Kertész) In order to have intense life on the markets market stalls should be as small as still achievable to do business in them. “To accommodate the greatest number and variety of vendors and to keep the cost of rent affordable, the size of each stall should be minimized.” (Spitzer et al., 1995) There might be need for one big supermarket, and even the central market in Budapest has a supermarket on the -1 floor, however it should only be a supplementary function.

It is the many little shops which give life to the market. One can never get bored since it is so quick to get to the next stall and have a look on another pile of goods. The numerous many little stalls help circulations since it forces people to compare prices and go back and forth between stalls to make up their minds. With two steps one arrives into a different world of vegetables or cheese. And as we learned from Jane Jacobs (Jacobs, 1961) “the sight of people attracts still other people, is something that city planners and city architectural designers seem to find incomprehensible.” Allowing single vendors to occupy many stalls to create an oversized single-stall on the long run could ruin the mix, the intensity and the liveliness of the markets, and therefore should be avoided.

Thus markets differ from shopping malls and other shopping centres in the arrangement of space which helps enriching encounters and social activities. The ratio of aisle floor area over shop floor area is higher in markets. Markets foster the highest possible number of stalls to be arranged within them by having small available rental places and in turn this policy would also keep customers off the limits of the shops and forces the people to go around the stalls. Since most of the people are visible on the paths within the shops or stalls there are more people to look at, there are more chances for social activities. Both of these architectural features are contributing to the good quality of urban public spaces since they foster encounters and help the density of social activities. Therefore it is this physical attribute what helps creating the lively, open atmosphere within the market.

“The activity generated by people on errands, or people aiming for food or drink, is itself an attraction to still other people”(Jacobs, 1961) Looking, gazing, watching are according to cognitive theory important stimulus seeking behaviours. In a market as in many other public spaces we want to see each other; it is the view of other people, the swarming of people which makes the quality of our urban life. In markets there are plenty of opportunity for flaneurism, for watching other people to browse, to select, to shop and to chat with vendors and fellow shoppers. Thus we can argue that markets are certainly unique shopping spaces since due to their architectural layout they foster social activities, they promote social interactions. For this reason the quality of the public spaces of markets is worth further analysis. In the next chapter we will look at the most

important architectural attributes of markets which are perceived as important factors for high quality public spaces.

4 ARCHITECTURAL AND MANAGERIAL CONCERNS FOR MARKET PLANNING

In Budapest the most common form of a market is the covered market hall. There are only a few exceptional temporary markets, such as the so-called MDF car-booth markets and the weekly market on the Havanna housing estate, which are both open markets and work only on Saturdays. Most markets however are more stable and are open daily from 6 am until 6 pm, except Sundays. The layout within the market halls is traditionally just a few rows of tables within the main hall area, while small shops are lined up by the walls of the market. At some markets even in the main hall individual stalls have been installed, such is the case at the Central Market. The most complex buildings, such as the Lehel market and the Fehérvári úti market can have more levels and also can accommodate other functions such as the post office or pharmacies, so complex that many people would not even call them markets any more. These markets all manage to flourish social activities within them although to various degrees.

Looking at the many different types of market layouts one starts to wonder why one is working better than the other. What makes good quality urban design when it comes to markets? In this chapter I will analyse three different aspects for good quality market design: the arrangement of the site, some amenities at markets and the role of nostalgia towards the “lost rural paradise” in the form of family farmers. Whatever is the type of building of the market these factors are important for the quality of the space and for the quality of life the space can generate.

4.1 Arrangement of the site

The arrangement of the site is the backbone for any market and something which have to be thought about in advance, since these are characteristics which cannot be altered later on. Considerations include obtaining the right size for the market, the system for uploading goods, and allowing good circulation within the market. I will give detailed explanation of these aspects in this chapter.

The market works well if it occupies all the space available for it. If there are empty stalls and empty areas it results in a feeling of decay. The market is best if it has a somewhat crowded atmosphere. The market is good when it is full. You have no desire to enter an empty market. It is extremely difficult to estimate the right size, which gives this pleasant well proportioned feeling, but endures the peaks of Christmas and Easter too. (Kertész) However municipalities at many market renewal projects aim to increase the size of the market building, mostly for financing the cost of reconstruction. The size of the new market building is decided according to economical return considerations, and the size is blown up for higher rental revenues. From both social and economical point of view this argument is mistaken, since it will cause a somewhat loose space. Unless new market buildings accommodate new functions such as new community play areas or libraries, etc. or otherwise there are fundamental societal changes in the area – new transport lines to attract more visitors, new housing development, or changed travel patterns and its supporting parking facilities – there is not much reason for building a substantially larger market than what an old, well-functioning and not-overcrowded market occupies.

“The market was not an architectural challenge but a societal. There are so many personal interests at play at a public development. We were given an enormous programme, which, I am glad, did not succeed. Only two third of the original plan has been created because the municipality run out of money in the last moment. I personally believe that the first part, the open hall would have been enough for a bit more compact, but still well functioning market, and would have given more open public space.” (Berzsák)

The size of the new market is decided in the municipality. It should be the role of the local authority to commission studies about the use of the market, to create a sound programming for the development project. (Kertész) A usual solution sought by local authorities to increase the floor area of the market on the same site by introducing second, third layers. This would create a more relaxed space distribution on one level and at the same time doubling the rentable floor area. However second layers rarely work.

What we learned from the 100 years of experience of building market halls, that it has been confirmed that the galleries don’t work. In the central market hall it is a tourist attraction place, but it does not work in any other place. The market hall in Hold street is echoing from emptiness. It is a cursed idea. We managed to get

around it by putting the parking lot on the top of the building, so for those who arrive with a car that will be the main floor. Muddled up the senses of people with this idea and aired some life into the upper floor. (Rajk)

There are definitely problems with the gallery at Csepel market, where no business could be charmed up to the gallery. It could be added that second layers are prone to be dead if the main floor area is in itself too spacious or the gallery is not comparable in size with the main floor area: it is just an add-on. In Csepel both of these assumptions are true. Such non-essential, non-functional second floors are the hardest to rent and the hardest to give life to them.

The manager of the Lehel market has taken the two levels of the market as a challenge. He was the first manager to invite different public functions into any market hall in Hungary, even before shopping malls have started. He invited the post office to be settled on the gallery level of the market, and later on the land registry office and a pharmacy. In this way it is only the main floor of Lehel market which is still a market and the second floor is not a market any more: it is more a shopping centre or a mall, since the new functions do not have the same outward looking atmosphere, but rather they are individual shops. Another clever deception has been done at the Fehérvári uti market for the benefit of giving life into two layers: the street entrance is halfway between the main and the first floor, while the size of the two levels are nearly the same, so it is really hard to decide which is the main floor.

In the market it is the hall I am most proud of. It is a very harmonious space. And we managed to create a good circulation system, with the escalators, the stairs, and the bridges. It is easy to look through all three levels and easy to circulate among them. When you enter you feel the swarm, the noise but at the same time the building, the built environment gives to it a kind of strength, a frame, maybe because of the materials, the walls and balustrade are made of cement, it is massive but at the same time pleasant. (Kertész) At Fehérvári uti market even the third level – which is the level for the restaurants and buffets – is widely used. And it is due mainly to the ease of the circulation with the inviting escalators and the many options to move between the levels, which just shows that it is not really the number of levels but the ease of circulation which matters. The gallery level works ok, but would be much better if there would be more connections between the main shopping area and the gallery. (Vörös)

“To facilitate circulation and comparison shopping, nearly all public market halls operate on only one level. Basement or second-story spaces generally are difficult to lease, and the businesses located there often do not perform well.” (Spitzer et al., 1995) It is therefore not necessary to stay only on one layer within a market, but rather it depends on the ease of circulation whether a double or triple layered market would work or not.

Wide enough aisles would accommodate shoppers to stop and chat without disturbing the flow of people, otherwise number of small talks and spontaneous conversations would lessen. However if the aisles are too wide people would be too worried to start talking to other people. It is the closeness, the crowdedness of the place that people are forced to bump into each other which helps them to start conversations.

The ease of circulation at markets not only means the flow of people but just as much attention should be given to the circulation of goods. On contrary to the social encounters generated by bumping into each other at markets, it is rather distracting when big bulky carts knock down people, or force them to move and spoil the ongoing conversations. The most obvious aim in terms of the free flow of people: “that goods and people should not meet before they meet at the stalls”. In other terms they should not cross each other’s ways during uploading. The traditional way to solve it comes with time-regulations, but with changing patterns of wholesale markets it is becoming less and less capable of managing uploading. The rhythm of inflow has changed and instead of only arriving at the early hours of the day, now it is throughout the day that fresh goods arrive to the market. Than another option is to use – if exists – the cellars for the transport of goods and having internal corridors within the building for the stalls. Basement levels are also useful for storage capacity allowing minimal space-use of the main floor area by single farmers.

Another popular option is to have outdoor upload for the market. This would mean that the stalls around the walls of the market are all facing inwards, and that individual vendors are able to park their trucks next to their shops back-doors. However this option should be avoided if possible. Since the space given shop owners would prefer park their truck at their shop entrance allowing only the minimal amount of goods to be taken into the shop. This custom however blocks passageways and gives an un-orderly look to the whole market.

To put it shortly the market works well if it occupies densely its space, if it has a good circulation which eliminates the disturbing encounters between goods and consumers. Compact, full but not overcrowded, is the essence of a good functioning market. For this reason the layout should be easy to understand and also should be easy to get around. Stalls and shops should be kept to a minimum size, while aisles should give a comfortable space to pass by people but not as wide as to prevent from zigzagging. And if the local authority is aiming for multi-layered market than the layers should have equal importance and multiple and easy to use options are essential to circulate between the two levels. If possible underground uploading and storage facilities would help good circulation within the market, or otherwise strict time restrictions for loading should be enforced. At the next chapter we will look at the factor of additional amenities for well functioning markets.

4.2 Amenities

With the dawn of supermarkets shopping has changed its fashion and its rhythm. New shopping markets also changed our shopping habits. If markets are to survive the upsurge of shopping malls and hypermarkets they have to accommodate new requirements for comfortable shopping. “These days we do not have time to go to the market. Maybe the elderly have to whom it is a great place to hang around. But we are more worried to find a parking lot, or not to overrun the time meter.” (kertész) It is true we need more time at the market. Comparing qualities and prices, lingering around it takes more time than just go to the supermarket. If physical conditions improved users would lengthen the average time spent at public spaces. This is true when a street gets pedestrianised (gehl), but also it is true for markets. We spend twice as much time at markets as it is necessary to do our shopping. According to a survey at Lehel market hall 60 % of people spend more than 3 hours at the market at once. It is the clear cut result of social activities at the market. “This is why we have decided together with the deputy mayor, to allow cars to park for free for two hours. One can easily do their shopping in 1 hour, but than they would have no time for social life.” (Balogh) Having this in mind the management of Újpest market when opened a car park they let it have free for the first two hours.

Another idea was developed by the Lehel market which also relies to a higher degree on shoppers with cars. They found out in a survey that the average load people carry is about 6-7 kilo, while the average time spent on the market is about 50 minutes. To boost shopping capacity of customers and to encourage them to spend more time at the market they introduced shopping carts familiar to us from big supermarkets. “First in Europe it was at Lehel market that we introduced shopping carts at a market. Shopping habits have changed, but when I first introduced even my colleagues were dubious. Now people are complaining at the municipality that there is not enough of them. We have to follow the changing shopping habits.” (Vörös)

It is thus the change of shopping habits to which Lehel market responded positively. “We had another dilemma with the market: to have a shopping cart at the market or not. The biggest difference between a market and a supermarket is that in the market the goods I have in my cart I have already paid for. And thus we approached the company producing the shopping carts to develop a type which could be closed from top, with a kind of lid. We should not vision customers only in the old fashioned way: that people come with two big baskets which they would drag home. People will shop less without a shopping cart and thus it would hold back the good functioning of the market.” (Rajk)

Thus changing shopping habits and needs should be accommodated at markets. It will not be a fairy-tale market from our childhood any more, but people will continue using them. And as long as the essential features of the market will not be destroyed by compromises they are worth taking. Changing shopping habits are visible not only in the use of transport to get to the markets but also on the activities performed at markets. Markets are becoming not just mere shopping areas but social hang-around places and thus the importance of leisure activities, cafés and bars and social happenings are rising.

In recent years open air Garay market has been redeveloped into a shopping mall-housing estate complex while the market was transferred to the basement. Shops are empty in the mall and thus also the market struggles for life, half of its stalls are always empty, there are few customers who can find their way around and still like the place. However it has one lively area: an open area in the form of a horse-carriage where people are free to sit down to eat or just wait, relax. The same style of sitting possibility has been installed at Vác market where vendors started to alter the form of the market to their own taste. “The owner had put out a kind of grape harvest cart something, which is ok at a harvest but here at the market? People are not

supposed to sit down at market. However if there had been a request, it should have been down precisely, and at another area, but not just like that." (Sáros)

For a market to foster social activities it is important to have places designated for relaxation, for eating or drinking. Pubs, cafés and eateries are essential parts of any lively markets. Amenities for eating would foster users to linger around in markets, spend more time and boost even more action. "In public markets, commerce coincides with intense social interaction, so adequate space where people can linger is desirable. Benches or tables and chairs should be provided if food is sold for eating on the premises." (Spitzer et al., 1995)

However these areas are very difficult to create at markets, since the functioning of markets would eliminate any rentable space for more commercial activities, thus reducing even the in-designed spaces for lingering. "The problem is that life would wipe out such places for lingering. If it will not be in the way than there something else will be put in its place. We can't really create comfortable sitting areas since the management will eradicate them and the space will be rented for money. Maybe outside the market, that would be good and at Fehérvári although there are some possibilities to sit down, however that is not very welcoming." (Kertész)

This need for sitting and chatting is a new impulse at markets and articulated with the hollowing out of other shopping spaces. Since commerce in the narrow sense has more or less abandoned markets as institutions, with other institutions having much higher revenue, they are searching for their own niches. Thus being able to sit down at markets is becoming an important factor for taking pleasure in shopping. This is the case at Vienna Nashmarkt but also at Fehérvári uti market which has a striving eat-in area. The secret of this market area is that the benches, chairs and tables do not belong to any individual shop-owner, they are free public spaces overlooked by the community of the restaurants. So people could freely sit down, even to eat their own food, sandwiches and bakery products. The more neutral a sitting area becomes the more attractive it will become for market users to linger around.

4.3 Family farmers

Thus communal spaces where people gather, maybe eat a sandwich or have a cup of coffee are getting more and more important at markets, just as much as the marketing power of family farmers. Family farmers, called őstermelő in Hungarian are the icons of Hungarian markets. According to the general opinion they are not trade businessmen but farmers who sell their home-grown food and they are the essence of the market experience.

According to my experience the market is different from a mall because here we have family farmers. We are lucky to have in a year around 120-150 family farmers at our market, who would bring in the freshest of the goods, picking the goods on the day before. They are real family farmers you can see it on their dresses, on their products. For example they would not come in the winter months, since although they have some vegetables, potatoes, onions or apple but not that much. (Balogh)

However in most of the cases this idea seems to be outdated. "What have changed in the life of markets is that these days there are no more family farmers. It is just a mere legend. The classic old lady who would get up at 2 or 3 am to take out fresh radish and carrot from the soil to pack it up and take it to the market… this is just wishful thinking, a kind of nostalgia. Instead experience shows that these people are lacking capital to rent a proper shop. So they also go out to the wholesale market in the morning and resell whatever they buy at the market." (Rajk)

Family farmer is a vanishing occupation and most of the sellers at these stalls are just tradesmen without enough resources to rent a shop. There are other urban legends told by the architects themselves that professional vendors would hire old ladies to dress up in old traditional folk costumes to sell at the stalls opposite their shops.

Whether it is true or not it shows the importance of family farmers in the marketing of markets. I am not sure, that the market would remain market without the "family farmers" (Rajk) It shows the level of attachment of people to family farmers and the kind of trust and authenticity they create. It is not the farmers themselves but the space and the atmosphere they create which is important. They are part of the market show. Family farmers are part of the marketing features of the markets.

It is not only the people themselves but the physical space created by the presence of family farmers within the market hall is important for the atmosphere. Therefore including a space for family farmers is essential for the "feeling" of the market. There is a strong pressure on market managers from the society in search for authenticity. The part of the market where the open stalls are is the liveliest in Lehel market hall. At other places for example at the Central market it is a different case. Here family farmers are less numerous and less visible as well, being at the back entrance of the market. "The most thriving and most profitable part of the market is in the middle. There where we have installed the stalls for family farmers. With the way to put the stalls into the middle of the market we could re-create the old fashioned market atmosphere of the old Lehel market." (Vörös) This is the place within the market with the most talking and watching, this is the loudest corner.

The professionalisation of the farmers brings challenges for the physical space. „Changes in the occupational structure are also more visible. Even at the family farmers' stalls – from which there are 100 at Lehel market – they would rent 4-5 and they would bring in the goods by small tracks." (Rajk) This process is capable to eliminate the atmosphere of the space, therefore it should be guarded carefully. If we aim to achieve a market which is not only a shopping experience but also a social experience the spatial arrangement of family farmers are important in the arrangement of space of the markets. It is not the authenticity of the food but the authenticity of the space which matters. For the latter it is more important to maintain the small-stall structure, not to allow the compilation of stalls into a mega-stall. It is even more favourable to create a space for other even charity merchandise for NGO's, school etc.

Amenities at a market have to be responsive to the changing needs and shopping habits. They have to cater for the changing habits of transportation, of changed farming patterns. Changing supply and demand structures are in odds with the atmosphere of the markets. However it will not prove to be favourable to rigidly cling to old traditions but we should be able to find the space of the market within this new structure. If it is the "marketplace" atmosphere which counts than we should be able to provide more space to linger around more amenities for sitting and chatting. And finally the reduction of family farming around Budapest should not lead to the weakening of the function the spaces of family farmers played in the life of markets but other authentic and small scale vendors could replace their places and take up their role in the social space.

5 TO CONTROL THE UNCONTROLLABLE: MANAGING MARKETS

I was accused for closing off the market at Fehérvári street. I was asked: What kind of a market is where you have to enter through a door and it is not even visible from the outside? However it was the expressed requirement of the owner: to close off the market. It was purposeful because they were in constant confrontation with the district authority, with the city authority, with the police that they penetrate the surroundings. (Kertész)

So far we have treated markets as ultimate urban places for social activities. Therefore it might sound strange that architects are ready to talk about markets as a cancer on the body of cities. It is another paradox of the markets: we like them, because they burst with life but at the same time it urges us to control this life. The most common expression and the tasks architects seemed themselves to be faced with concerning markets was that markets have to be controlled. Markets –since they are such an intense urban activity – invite all sorts of spontaneous activities: small street vendors, many of whom could be selling unofficially goods from obscure origin, and also beggars, homeless people who hang around giving help in moving heavy stuff in return of some vegetable and also petty crime. On Teleki square market there has been even a washing machine on sale in the middle of one aisle, and once I could buy real cheap – probably stolen – bicycle from the bartender. Markets cannot stay within their boundaries, they overflow their limits. Whatever hard an architect tries to control the market through vigorous design and activity planning life would overgrow it like a rainforest. Stalls would install small umbrellas against the sunshine, or put up nylons against the frost and cold, would make their own signs and advertisements or would attack aisles with their merchandise.

In Hungary the problem with markets is that it is all penetrated with the repulsive atmosphere of the market, which would infiltrate the space and quality of the surroundings of the market. And it is all because it is impossible to stop at the limits. A market would sprawl, It lives a life of its own and in no time would it become entirely uncontrollable. Stalls would shoot up from nowhere, would grow in number and illegal vendors would appear and dirt all around it. It is like a tumour which would grow uncontrollably. This is

terrible. We cannot manage a market as a closed system, which would guarantee that it will works in a cultured way. (Kertész)

The bursting life of markets is not seen as desirable by city leaders. Markets are synonymous with dirt, rubbish, with unwanted elements, with smuggling, with stinking. Therefore markets have to be controlled. However as soon as a market is deprived from all its dirt, noise, smells and frenzy it would become a supermarket. it is a strange paradox and a real urban development challenge to keep the atmosphere of the market, however within its boundaries. The question to be answered is how is it possible to control a market without loosing its atmosphere, without loosing its social activities. If a market will be part of a city-renewal programme this aspect also has to be taken into account. If the urban shopping experience of markets are to survive for many more decades it is important to learn how to control market activities.

There are two basic different methods to control markets, both having their own consequences for social activities. The two methods are to control markets either in space or in time. Both of them have its architectural and urban design consequences. Controlling markets in time would mean that markets are not available as public spaces for 24 hours a day. They would become temporal, visible only on special days. The control of markets in time is seen as an ideal in Hungary. “On a Friday morning [In Gent] trucks encircle the market place – there is junk there too – for an open air market. But conversely to the market in Vác at 2 pm as for a miracle everything disappear and at 3 pm one can eat from the pavement because it is all cleared up. There are no tables, no boxes, no wrappings, no stalls, nothing visible left from the market.” (Sáros)

Market activities which are controlled by time would leave market squares for the evenings or on non-market days as open public spaces. This form of market is idealised within Hungary but at the same time conceived as unmanageable for mainly two reasons, from the vendors’ stance and the other is from the managers’ stance.

“In Hungary it is absolutely impossible to have a temporary market, mainly from the vendors’ point of view. If he has to remove his goods and even his stall is removed and the space is cleaned after him, well he would not fell secure enough to be able to come next week. It is a security issue for the vendors; the continuity of the rental is only felt evident if the stalls are rented continuously.” (Sáros))

“The model of open air temporary markets proved to work for thousands of years, however at the moment it is not an option in Hungary. Everything is ridiculously over-regulated, to the point where it becomes unconceivable. Every authority puts in its own regulation. (Cságoly)

Since the control of market through time is perceived as inconceivable in Hungary; managers, owners and architects turn to control the markets in space. What it means is that outside of market hours the market is not visible, to make its boundaries clear and visible. It is done usually with walls closing it off from the surroundings. In this way it is easier to control the activities of the market and to decide on responsibilities.

“From the point of view of management it is absolutely necessary to be able to close a market.” (Sáros) The reasons for closing off the markets had many very understandable reasons: health and hygienic considerations, urban beautifications, financials – since it is easier to collect the rent – and as we have seen in terms of illegal activities, responsibility issues.

These two kinds of control mechanisms of markets have different consequences for social activities. While an open air market could boost activities in a neighbourhood, it is also a shallow urban space. Out of market times the urban square would be usually empty and deprived of activities, unless the market is so small that its place can be taken up by a café. Larger markets would leave emptiness for the urban spaces. The same emptiness is different for the markets halls, since the building itself encapsulates the void of activity. It is also true although that the market hall is also more rigid and thus it would not allow alternative functions such as concerts and other gatherings. The empty space left after markets should also be carefully examined when deciding on the type of the market.

The open air market is a flexible use of urban space since it can be easily removed. It is beneficial for the vendors, especially in the cold winter months that these markets operate only a few hours a week. In the many open air markets in Paris stalls are erected only twice a week for about 6 hours. On the other hand this flexibility has consequences for the number and intensity of social activities on the market. They treat the urban space very generously, but at the same time they do not offer that much possibility for lingering as the market halls would provide.

Infrequent, open air markets, although very proficient in managing space, concentrate much more on the narrow commercial activities and allow less opportunity for social activities, for social gatherings. Installation of amenities such as common sitting areas is mostly missing from open air markets. They do not facilitate the smooth operation of cafés and eateries, and thus they are weaker in building up social communities.

On the other hand the market which is regulated in space is much more flexible in time. A covered building fosters all kind of activities. The opportunity offered in market halls for sitting and chatting is a strong force for the development of regulars. Sitting areas are not typical for open air markets but for market halls." (Rajk) The market is open 12 hours a day, 6 days a week and is bearable in nearly every type of outside weather. Thus it is a more predictable space.

Deciding on the type of control over markets local authorities would choose also the type of social activities and social life which could develop at markets. Whether it will be just some nodding and shaking hands or also sitting and chatting – will depend mostly on the construction of the time and space of the market.

The most recent tendency in Budapest is stemming from this constant bad conscience for creating closed market halls. Architects try to re-create public spaces within the markets. To close off public spaces within market areas, to create semi-public spaces which could be regulated, and life on them could be monitored. However the question is still open that they will also be only an illusion of public space (Banerjee, 2001) or will they be part of the transformation of public space and restructuring of community life and places of social inclusion.

„We wanted, since we had no chance outside of the market, since the roads are busy, to create a public space within the market. This is why we created this small park, which is quite, but also it is possible to close down with the market." (Berzsák)

This tendency could have different effects: to recreate the agora - the open public space – within closed boundaries is to loose its main feature, to create semi-public spaces. We privatise the public spaces. This is the question for the next decades to decide whether these semi-public open spaces will really work as community spaces and how they will affect the in-between spaces around markets, the squares whose functions had been transferred into the belly of the markets.

6 CONCLUSION

From its rustic outfit and openness, markets invoke nostalgic sentiments in people. There is a natural urge in people to go to markets, to experience markets. Also people spend more time in markets than they would need to finish the strict necessary activity of shopping. The quality of our urban life depends greatly on the social contacts we might have with our neighbours, also on our relationship with complete strangers. Markets offer a societal space which is denser and more impulsive: there are more social interactions and encounters. But we have just too often seen redeveloped markets which lag behind the original atmosphere of the run-down previous market. Markets can be communal spaces, but the functioning of the life on markets should be understood both by local authorities and architects so that they regeneration would reinforce this social quality.

"It is equally possible through planning decisions to influence patterns of activities, to create better or worse conditions for outdoor events, and to create lively of lifeless cities." (Gehl, 1971) Understanding the mechanisms of the markets as public spaces allows us to further influence social activities, which is especially important when planning new market areas.

Many of the social qualities of markets can be found in the physical arrangement of the space they occupy. A market is different from a shopping mall thanks to its inner structure: numerous small outward looking stalls would show openly the activities going on at markets and would allow people just to look and gaze other people. The activities going on in the public area would further enhance the density of encounters and social activities. The physical layout of the markets enhances social activities and foster social encounters. The necessary activity of shopping is transformed into a pleasure seeking social activity.

However it is also true that shopping habits and needs have changed dramatically with the dawn of shopping malls and big supermarkets, which have consequences for other, more traditional forms of shopping, such as markets. Markets will not survive if these new needs are not catered for. While markets are important social

places, we should not forget: this is a competition. If I only take a market as living from its traditions and running as a public facility left from socialist times I will loose in the market forces. (Vörös) Thus markets have to accommodate new needs such as free parking and shopping carts, but at the same time it should distinguish itself from markets through the many places and activities available for social interactions. It is a kind of revised traditionalism which would keep markets not only as lively urban places but also places with strength to keep neighbourhoods together and to support social ties.

My experience is that the least specific framework I create for the life within a school or within a market, the best it is going to work. From this follows that we should start from zero and should let it develop. We shouldn't start straight away with erecting a building; we should leave it to breathe freely, to form and to develop. (Cságoly)

The biggest challenge for the redevelopment of markets is that they are both welcomed and detested urban spaces. They are full of life but at the same time they sprawl into the surroundings causing disorder and civic discontent. In the eyes of architects and local authorities markets have to be controlled or in time or in space. Since controlling mechanisms have consequences on the social activities of markets, thus controlling leaves local authorities with the difficult task of balancing social activities of the markets.

We have learned from the examples of Budapest market renewals how to influence patterns of social activities in markets, how to create better conditions for a lively market atmosphere and thus how to help creating lively cities. However there are no exact measures, a golden rule to give for market regeneration. The market is a very mobile function. Of course we should give space for social encounters, but it is in constant change. What works at 8 am will definitely not work at 4 pm. Not only spatial, but also temporal factors are at play. You cannot solve a market in a rational, analytical way. The more I concentrate on the small, analytical problems the less my building will work. All its details will work, but the building as a whole will not. I take pleasure in things and do not want to solve them how they work. Intuition will show a few options which will help. (Cságoly) The social construction of the site is so strong that life would always slip out of our analytical hands. Every market site is a world in its own and the quality of the urban space also depends on the social, physical and environmental conditions of the neighbourhood.

Interviews were conducted during summer 2009

- Balogh Angéla (manager), Újpest market
- Berzsák Zoltán (architect), Csepel market
- Cságoly Ferenc (architect), Fény utca market, Gödöllő market

Polyrational strategies for sustainable energetic development of space – the example of Leipzig

Christian Strauß

(Christian Strauß, Fraunhofer Center for Central and Eastern Europe, Neumarkt 9-19, 04109 Leipzig, Germany, christian.strauss@moez.fraunhofer.de)

1 ABSTRACT

The project "The sun is rising in the east – energy efficient city of Leipzig" is a joint project funded by the German federal Ministry of Education and Research (BMBF). Main objective of the project is to develop an innovative concept for the future procedure of developing Leipzig as an energy efficient city. Therefore the concept contains "energetic-spatial" topics (in the sense of a combination of both strategies) against the background of demographic change.

As a first step this concept will be developed in the urban district "Leipzig east". This is a quarter of the so called Wilhelminian style. It suffers from a shrinking population and changes in the population structure. In spite of perennial reconstruction measures the area is suffering from a backlog in reconstruction. Therefore it is necessary to go on with the urban regeneration. Generally, potentials to integrate energetic needs can be found, but on the other hand it is difficult to realize them because of the socioeconomic structure. Therefore reducing energy is not the only objective. To find sustainable solutions it is essential to include socioeconomic demands and restrictions: Not the best technical solution can be realized but a solution which also considers social and cultural aspects and which can be financed at least.

Within the project, "energy" will represent a benchmark for the evaluation of the technical dimension of the "city system", as well as an object for the planning process in the political dimension of that system. For the first time, strategies to handle with the spatial consequences of demographic change and strategies of mitigation will be combined in this project. The results of the concept will be integrated into the strategic district plan for Leipzig east. Leipzig thereby shall become a role model of urban reconstruction in Germany and in Europe.

2 MAIN OBJECTIVE OF THIS ARTICLE

The dynamic changes currently taking place in society and space call for a rapid response. Therefore, research needs to highlight alternative approaches to achieve sustainable solutions. Concerning sustainability of spatial development which includes energy efficiency it is necessary to create new strategic and action plans which basically have to be developed by local actors.

Main objective of this article is to emphasize that a modern urban energy concept should integrate several dimensions, especially it is necessary to combine the two policy fields of energy and of space. For that it is obligatory to develop an integrative and cooperative governing process. Following this objective, "energy" should be seen as a new object of spatial governing process. It is essential to find a sustainable answer which integrates also the demand side into the strategy and action plan to develop urban energy concepts. On the whole, the article refers to the question of urban policy.

3 EXAMPLE OF LEIPZIG

At first it is necessary to give a short impression of the city of Leipzig to understand the challenges and the background for preparing a sustainable energy concept. Leipzig is a big city in East Germany. In 1989, not only a political transformation has begun but also social, economic, cultural and ecological transformation processes. Looking back to more than 20 years of these different forms of transformation it has to be emphasized that the city – its physical and its societal structure – has changed in an enormous way and that this transformation processes are still going on (Doehler-Behzadi, Lütke Daldrup 2004). A lot of problems could been solved – but not all. The unemployment rate is very high. The population has decreased from 1989 until the late 1990s because of migration to the suburban areas of Leipzig or to West Germany. Although the current height seems to be stable or even to increase again the density is much lower than in the early 1990ies. Concerning the spatial structure, the city has to cope with waste land and with apartment vacancies. This has got impacts for society, space and for the effectiveness of the technical and other infrastructure.

Leipzig has got a specific local situation with energy related challenges. That is why on the one hand there are also specific challenges for sustainable forms of energy policy. But on the other hand the transformation process in Leipzig has got a lot of similarities to other cities in Central and Eastern Europe. That is why it is useful to share experiences with each other and also to use methods and results of existing projects. But it is always necessary to find out if they are exactly transferable or if a modification is required.

To cope with these spatially related problems in East Germany it was not possible just to adapt the traditional understanding of a policy of space which had been developed in West Germany but to develop new forms, with new content and new instruments (cf. Oswalt 2005). On the whole, sustainable urban development has to follow two approaches to cope with these dynamic changes: At first it has to implement different sectors in an integrative way which influence the spatial structure (cf. Leipzig Charter 2007). Then, because of this integrated approach it also has to be organized in a cooperative way (cf. Healey 1995) – as the power to analyze, to plan and to change spatial structures does not only belong to the public sector. Different actors can be identified:

- Government of State
- Local authorities
- Public utilities
- Owner of building
- Inhabitant
- Users
- Consumers

These different actors have got different rationalitites, different perspectives and also different opportunitites to implement their objectives. Especially if the existing city (the "built city") should be transformed – and this is the main task in the future – it is obligatory to have a development together with private actors. An urban energy concept should be a part of a superior strategy of urban development. Therefore it should be discussed if and how an energy concept also could follow these two approaches.

Concerning energy related projects there are several initiatives in Leipzig. Not only public authorities have begun to develop strategies and actions plans like preparing an application for the European Energy Award or finding strategies for adaptation processes in Leipzig Region against the background of climate change. Also some private groups discuss and realize interesting solutions in this subject. For example there are two districts which have not been refurbished on the whole until this moment, the owners and the inhabitants of the buildings have now initiated bottom up plans to develop their district. The possibilities of energetic improvement are discussed together with a lot of other demands and objectives.

But although energy is already a topic in the perception of several actors an integrated and cooperative solution is still missed. That is why a project consortium has applied for a research project in Leipzig which should develop an integrative urban energy concept. In the following chapter this project is described.

4 RESEARCH PROJECT "ENERGY EFFICIENT CITY OF LEIPZIG"

The project "The sun is rising in the east – energy efficient city of Leipzig" is a joint project funded by the German federal Ministry of Education and Research (BMBF) (www.energiemetropole-leipzig.de). Main objective of the project is to develop an innovative concept for the future procedure of developing Leipzig as an energy efficient city. Therefore the concept contains "energetic-spatial" topics (in the sense of a combination of both strategies) against the background of demographic change.

As a first step this concept will be developed in the urban district "Leipzig east". This is a quarter of the so called Wilhelminian style. It suffers from a shrinking population and changes in the population structure. In spite of perennial reconstruction measures the area is suffering from a backlog in reconstruction. Therefore it is necessary to go on with the urban regeneration. Generally, potentials to integrate energetic needs can be found, but on the other hand it is difficult to realize them because of the socioeconomic structure.

The joint project is split up into different working packages "energy space", "actors", "software" and "service engineering". In every working package other objectives are more important so that it is possible to

analyze the city from different perspectives as system of energy, a spatial system or a system of users. As results of the project, an energy-spatial concept will be developed, an energy-spatial consensus will be concluded, a computer-assisted communication platform will be prepared and a service engineering will be introduced.

All results should serve the main objective of the project to identify strategies of highly reducing the energy demand in the east of Leipzig and should show potentials for energetic optimization, increase public awareness and lead to new forward-looking businesses. Based on an evaluation of the current energetic structure, the concept will show strategies and actions to save energy consumption. But reducing energy is not the only objective. To find sustainable solutions it is essential to include socioeconomic demands and restrictions: Not the best technical solution can be realized but a solution which also considers social and cultural aspects and which can be financed at least.

To find out what the perceptions of the different groups and actors in the inner-city are, existing superior (political and societal) and individual strategies are analyzed and optimized. Thereby, a decentralization of technical infrastructures is discussed although the dominance of the existing district heating network in the east of Leipzig has to be accepted.

Within the project, "energy" represents a benchmark for the evaluation of the technical dimension of the "city system", as well as an object for the planning process in the political dimension of that system. For the first time, strategies to handle with the spatial consequences of demographic change and strategies of mitigation are combined in this project. The results of the concept will be integrated into the strategic district plan for Leipzig east. Leipzig thereby shall become a role model of urban reconstruction in Germany and in Europe.

The first part of the project has got a time period only of twelve months; it has started in June of 2009 and will go on until June of 2010. Within this period it is only possible to develop a concept for the future. The second part of the project for which we have to apply again will focus on the implementation of the concept. Only three to five of the current 15 projects will be funded in the next period which will take five years at a maximum. But even if we will not be funded the project will have been successful because already now it is possible to discuss the challenges and solutions of a spatial-energetic urban development in Leipzig and to sensibly people and organizations for this topic.

Four project partners are mainly involved in the project:

- Fraunhofer Center for Central and Eastern Europe (MOEZ) (coordination)
- City of Leipzig (department for business development)
- University of Leipzig, Institute for applied Informatics (InfAI) e. V.
- University of Leipzig, Department for urban development and construction management (ISB)

The research project has got some advantages for the municipality of Leipzig. The concept contributes to a sustainable urban development. It also connects strategies and actions of spatial with an energy policy and it is strengthening the profile of energetic and spatial policy. Furthermore, solutions to overcome two crises – "climate crisis" and "socioeconomic crisis" – will be shown. Finally an integrative and cooperative concept for the district of "Leipziger Osten" (east of Leipzig) concerning spatial and energetic dimensions will be developed which combines objectives of urban regeneration and needs of technical infrastructure.

At the municipal authorities the project is assigned to the department for business development. But this is only for formal purposes. In fact, a lot of departments (e. g. planning, environment) are involved. Additionally, there is an exchange with several public and private actors, so called "dialogue partners", for example housing companies and public utilities. In this dialogue a new "energetic truth" as a part of sustainability will be discussed.

5 "CLIMATE JUSTICE" AND "ENERGETIC TRUTH" IN THE CASCADE OF SUSTAINABILITY

In the Leipzig project it is necessary to define what the impacts of climate change for spatial policy are. Therefore it is also essential to operationalize the normative concept of sustainability. For that two new terms have been defined: "climate justice" and "energetic truth".

Future strategies and measures of spatial development will increasingly focus on adaptation. Given the macro trends of spatio-structural influences, spatial structures will have to be reorganized: apart from socio-cultural changes in the demand for buildings and areas to live in, the positioning of agglomerations within competition as a result of technological and economic structural transformation, and the way in which fragments and the declining intensity of use in connection with demographic change are dealt with, sustainable spatial development will entail adapting cities and urban regions to the requirements of energy-optimized urban structures and the consequences of climate change (cf. Mörsdorf, Ringel, Strauß 2009).

Materially speaking, this new integrated viewpoint will necessitate reviewing previous models, strategies, aims and measures of spatial development. And in institutional terms, too, the traditional forms of control will have to be examined regarding their suitability in the face of climate change. This includes analyzing the actors and patterns of action as well as the instruments available. A suitable set of instruments for climate change needs to be made available which actors can use to ensure and restore urban development and regulation.

Ultimately, these two areas require a new type of analysis of the forms of transformation which, compared to other spatial-structural challenges, are beset by a considerable lack of clarity. Whereas for example in response to demographic change supply is adapted to changing demand , both demand and supply have to react to the changing conditions brought about by climate change. In addition, forecasts are very unclear and complex. The uncertainty arising from this fuzziness regarding future change is a source of risks – but also of opportunities as innovative solutions become possible (cf. Strauß 2009).

Adopting a holistic interpretation of climate justice of space, measures of mitigation and measures of adaptation need to be combined. In addition, climate justice also ought to take socio-political elements into account. Therefore the term contains:

- The requirement to be suitable for the climate (as environmental justice)
- The socially fair arrangement of these strategies in terms of standards of living and survival capability (as social justice)

In these spaces, innovations are possible with climate justice in a double sense. On the one hand, the haziness of climate projections ultimately leads to an inability to plan space and therefore enables individual innovation, while on the other changing sets of criteria form a breeding-ground for innovations of social justice in regional systems of innovation (cf. Fritsch 2005: 479–480). A climatically suitable spatial innovation system therefore consists of the two mutually dependent foundations ‘knowledge’ and ‘ethics’ (cf. for biotechnology: Koch 2006: 2). The system of innovation contributes to economic improvement and to social and cultural regional development. It hence helps a region as a whole to distinguish itself and to reduce disparities (cf. Schwinges et al. 2001).

A strategic target in future discussions and project dealing with energy consumption, renewable energies as well as climate justice is to publish and to discuss an “energetic truth”. This term can be defined in the following way:

“Accepting and disclosing of current energetic situation and its impact on the future of availability, consumption and costs of energy. The bounded rationality of politics, economy and private persons has to be accepted and alternative polyrational solutions for present ways of acting with all their advantages or disadvantages (costs and limits) have to be shown.” (own definition)

This term implies to enlighten the society about the status quo of energy consumption and the finiteness of fossil fuels as well as telling the truth about perspectives of renewable sources and future energy concepts. The implementation of the energetic truth goes along with the utilization of renewable energy sources, an increase in the efficiency and the adaptation of the current energy infrastructure in combination with the improvement of the physical structure of city as well as the question of decentralization of the main power supply and an energy efficient mobility.

The approach of implementing an “energetic truth” follows the concept of bounded rationality but also emphasizes the need of developing a new polyrationality (Davy 2005, based on Douglas 1992). Therefore it implies two major strategies with the focus on developing new methods of cooperation. The superior strategy sets the focus on the public authority which is in charge of the overall spatial planning process and therefore responsible to secure the welfare of the general public. An innovative connection between general and

sectoral planning is discussed during the process. The superior strategy also includes a dialogue with the public in form of public relations and workshops with the owners and the inhabitants of the district. The individual strategies contain initiatives of private actors which influence spatial development as well as an analysis of institutions and their patterns of acting. These individual strategies are attended by new service concepts like the computer aided service engineering.

Both strategies – the superior and the individual ones – should follow the principles for a sustainable energy supply (cf. Bundesministerium für Umwelt 2009):

- Guarantee security of energy supplies
- Strengthen economy
- Increase renewable energy
- Realize nuclear power phase-out
- Use coal in an efficient way
- Make power grid efficient
- Consume power more efficiently
- Reduce fossil-fired heating system
- Reduce emissions in traffic system
- Act international

In reality, a lot of objectives and actions follow these principles, but there are also a lot with conflicts to them. And it is important to say that the principles refer to different actors. In the sense of a planning process which includes the elements of integration and cooperation it is necessary to find solutions to reduce the conflicts between these objects. Within this discussion there is also another debate which becomes stronger: the debate about zero emission cities. The debate includes the discussion about the following theses (cf. IWU 2002):

- "Zero" is only a vision
- Zero is not absolutely 0
- The city is surrounded
- Integrated analysis is obligatory
- Reycling management is necessary
- Physical space: impact or result?
- How sustainable is the compact city?
- Polycentric agglomerations have got less traffic
- The only question is about "zero"
- People are catalyzers

In opposite to new towns like Masdar City or Dangton it is not possible to realize zero emission structures in the already built city like Leipzig. But it is necessary to analyse the current energetic structrures, to develop scenarios about the future development and to create realistic concepts. Therefore, the project has begun to find and to commuicate the energetic truth.

6 METHODS AND DATA COLLECTION OF THE ENERGY CONCEPT

Parallel to the two strategies there are also two possible methods to evaluate a city as an energetic system: top down and bottom up methods. Both methods have got advantages and also disadvantages. After all the project partners have decided to follow a bottom up method (in opposite for example to the methods of the European Energy Award). Again, this bottom up method contains alternative possibilities to analyze the energetic structure – they mainly differ between the basic units: buildings (units of the built city) or consumers (units of the societal city). Concerning, this question the project has decided to mix these two

units because it is necessary to have benchmarks regarding the built but also the societal city. Therefore the following indicators have been chosen:

- Construction year of the building,
- Quality of refurbishment,
- Form and quality of heating system,
- Size,
- Use,
- Owner (esp. private/public),
- Population structure,
- Protection of historic building
- Electricity consumption,
- Modal split and other indicators concerning mobility.

As the project has begun in June 2009 the data collection has not been finished. And it will also not have been finished for every indicator (especially concerning mobility) at the end of the first part of the project (June 2010) because the collection is very difficult. But until the end of the first part of the project we will have created an action plan which includes a set of indictors, first data collection and also the responsible actors and sources of the data.

A lot of problems exist with data collection because in Leipzig there is no central public authority which would be responsible for collecting and publishing or selling relevant data. This is not only a problem of Leipzig but of almost every municipality in Germany. In future it is not probable that this will be changed. That is why different ways to collect data have to be found. As an example we have tried but failed (at least until this moment) to get data from the guild of chimney sweeps. At least it is useful to establish a task force where all relevant public actors take part and share their data.

Another challenge has been to define the border of the site. There are different borders – administrative, statistic, funding, content – which also reflect different data, strategies, authorities. We have taken the borders of the ERDF district ("European Regional Development Fund") which already exists so that it is possible to combine socio-spatial strategies of EFRE with energy related strategies.

In the research project not the whole city of Leipzig will be analyzed but a part of it. This "pars pro toto" is in some kind more difficult to be analyzed than if whole of the city of Leipzig would have been taken because the results of the site have to be typified to be transferable to other districts of Leipzig and to get overall results for the city.

7 CONCLUSION

The Leipzig project of urban energy concept does not achieve a "high end solution" in the sense of a best energy system. But it achieves a sustainable solution which permits a pareto optimum including socioeconomic demands. This optimum reflects the restrictions of an integrated perspective: A sustainable urban energy concept aims not a technical energy system but a combination of spatial and energetic optima. Its content includes the dimensions of space, actors and – at least – energy. This does not mean worse but better objectives and actions.

The research project of Leipzig is specific on the one hand and has got transferable elements on the other hand. While empirical results have to be explained with the local situation it is possible to use the theoretical concepts of "climate justice" and "energetic truth" as well as the methodology of differing strategies and differing data collection for other cites. Especially it is valuable to discuss about a transfer of connecting spatial and energy policy to create really sustainable urban development.

In the future sustainable urban energy concepts should not be prepared separately but it is necessary to combine spatial solutions against the background of different forms of change like climate or demographic change. It is also necessary to combine spatial and energetic policy to permit integrated perspectives of urban

development. Furthermore it is necessary to realize cooperative forms of governing to achieve a cooperative governing process. These polyrational strategies are a key to sustainable urban development.

Position and Possibility of Large HungarianTowns in the Hierarchy of the European Towns

János Rechnitzer, Bálint Filep

(Prof. Dr. János Rechnitzer, Széchenyi István University, Hungary 9026 Győr Egyetem tér 1. rechnj@sze.hu)
(Dr. Bálint Filep, Széchenyi István University, Hungary 9026 Győr Egyetem tér 1., filep.balint@sze.hu)

1 ABSTRACT

There is a dual research objective: the position of the large Hungarian towns in the hierarchy of the EU on the other hand their possibilities and development directions. The population of the town dwellers has been gradually increasing during the last decades. It has resulted in the concentration of the new job openings, knowledge and possibilities. But unfortunately this particular trend has implied negative consequences as well. The issues such as sustainable development of towns, converting them places where well-being is guaranteed are both topical questions. The engines of the settlement networks s are such places where resources and activities are concentrated. Towns of the European Union can be arranged in groups based on several criteria. According to the research towns are terminated as European or trans-national towns (called mega) moreover national, regional and local centres (Rechnitzer 2007). Centres in Hungary – comparing to the capital- are significantly smaller settlements representing less population and more modest significance. The population of Budapest is about 2 million. The so called 8 big town's population is about 100- 200 thousand.

The significance of the national borders has been eased in the tremendous competition for the profit for the continuous development. The significance of several other potentials has been developed such as inexpensive labour force, knowledge, the number of the active population, the culture of the population, professional preparedness of the population. The potentials of the local values are upgraded and valued. Geopolitical potentials are also incorporated. A higher educational institution can be a special regional attraction being a professional headquarter of labour force reinforcement. Numerous young moves to towns and elderly also can be attracted due to sophisticated service supply. The significance local values, local traditions, cultural values and natural values are being kept at a high esteem evaluating the role of country living. Infrastructural changes modify the way of country living making transport and employment a mobile business. Competitiveness depends on the productivity with which a location uses its human, capital, and natural resources. Productivity sets the sustainable standard of living (wages, returns on capital, and returns on natural resources). It is not what industries a nation competes in those matters for prosperity, but how it competes in those industries. What Determines Competitiveness? Nations and regions compete to offer the most productive environment for business. The public and private sectors play different but interrelated roles in creating a productive economy (Porter 2008).

On the basis of all this it is acceptable that competition started between towns at first since this particular competition is all about for companies, tourists and the increasing number of the population. There is a very close connection between the towns and the companies since these two factors individually increase the attractiveness of each other. Qualified professional labour force, having intellectual language acquisitions is a significant factor to attract companies to launch a new business and vice versa a company providing good living standards attracts young, mobile labour force. (Filep 2009). As different countries, companies can be compared so can towns. But an only identical type seems to be worth being compared. Our research has been designed to position Hungarian towns into the hierarchy of European towns.

2 COMPETITIVENESS OF CITIES: MEASURES OPPINIONS IN FOCUS HUNGARY[1]

Recently – besides analyzing the regions – regional research focused on the successfulness of cities as well. It is not by chance, because more and more people live in towns. „Today there are more than 300 cities with a population over a million in the world (city region), and there are almost 20 among them having more than 10 million inhabitants." (Enyedi 2003). The population of the town dwellers has been gradually increasing during the last decades. It has resulted in the concentration of the new job openings, knowledge and possibilities. But unfortunately this particular trend has implied negative consequences as well. The issues such as sustainable development of towns, converting them places where well-being is guaranteed are both topical questions. The engines of the settlement networks s are such places where resources and activities are

[1] This part is writing of Bálint Filep by „Competitiveness and Area Organizing Fuctions of Major Cities" PhD Thesis, 2009.

concentrated. Towns of the European Union can be arranged in groups based on several criteria. According to the research towns are terminated as European or trans-national towns (called mega) moreover national, regional and local centres (Rechnitzer 2007). Centres in Hungary – comparing to the capital- are significantly smaller settlements representing less population and more modest significance. The population of Budapest is about 2 million. The so called 8 big town's population is about 100- 200 thousand. The Hungarian "big" cities are not compare with the European big cities!

Which are the factors which may serve the way forward in this competition and amend the positions of cities. Studies have been made earlier to compare and evaluate competitiveness on national and on international levels as well. We can read deeper analyses in scientific literature, which cover the way of development of a city and seek its reasons and motivating factors and contribute to the elaboration of the development strategy. The economic sphere and human resources and the connection between them play an important role in the different theoretical and practical measuring tests. In my opinion examining the competitiveness of cities and their surroundings is a really exiting topic. It would be worth observing the individual cities from their formation, because the choice of the site and the historical events formed the cities, their role, their society, their traditions and economy. Competitiveness depends on the productivity with which a location uses its human, capital, and natural resources. Productivity sets the sustainable standard of living (wages, returns on capital, and returns on natural resources). It is not what industries a nation competes in those matters for prosperity, but how it competes in those industries. What Determines Competitiveness? Nations and regions compete to offer the most productive environment for business. The public and private sectors play different but interrelated roles in creating a productive economy (Porter 2008). International examples show that nowadays competitiveness appears beside on the level of companies, higher education and several other dimensions, also on the level of nations, regions, towns. There is a competition for floating production factors like capital, skilled manpower. Several other factors can contribute to competitiveness; some of them can be expressed with exact indicators, but some immeasurable factors may also occur, which are debated in rational and emotional economics as well. The historical development also contributes to the conditions of today.

It is important to determine our aims and the devices to analyse while typing the regions. It is not easy to type regions; there are several possibilities. To limit the attraction field of towns is not simple either. In many cases this limitation is very evident, because almost every country has well known borders, the limits of the regions in the European Union show up on maps well, the Hungarian counties and small areas are also known. The borders of towns are a bit harder to define; the limitation of their attraction field depends significantly on the examined factors. In some cases the limitation is strongly influenced by the geopolitical situation. It is particularly true in the case of towns and regions on the nation's borders (Dusek 2004.) Competitiveness and welfare will be defined by several theoretical indicators. The most common are GDP, GDP/person, HDI (Human Development Index). In opinion of Berey and Nemes (1998–2001) the reason for the regional differences characterized by the indicator of GDP/P was mainly the regional discrepancy of the gross value added (GVA) per person[2]. In the opinion of Nemes, Nagy József (Nemes 2007) as a result of information explosion, it is possible to get information from many places of the world. It is questionable whether they can be compared. The mathematical statistical approach, typical of the 1970s-1980s, narrowed to more simple indicators. All these can be traced back to the fact that these comparisons were not made for scientific purposes, but to serve the supporting politics.

We can find comparing reviews with different indicators, related to a point in time or time range: innovation clusters for a development index by Grosz−Rechnitzer (Grosz−Rechnitzer 2005), components of Nárai (Nárai 2005) created by factor analysis. Horváth (Horváth 1999) analysed different international major cities based on individual indicators. Similar reviews have been made in other countries as well. Győrfy and Benyovszky analysed the productivity of work in Romania and the evolution of the regional competitiveness in the counties (Győrfy−Benyovszky 2005). Many of the methods mentioned above cannot be used during the analysis of the Hungarian towns, because a lot of data − e.g. GDP − is not available on the town level.

[2] Berey and Nemes published a method in 2002 saying that the ratio/figure of GDP/P often used to chracterize regional competitiveness and living standard (where P is for the populationi) can be divided as follows: GDP/P=GVA/P+(T+D-S/P), where GVA/P shows the gross added value per person, T+D-S/P shows customs- and productfees per person (T+D) and state subventions (S). GVA can be inscribed by the multiplication of the ratio of gross added value per person and the employed labour per person: GVA/P=GVA/E*E/P, where E means the employed labour (Berey–Nemes 2002).

Zoltán Nagy measures the level of social-economic development with a manifold indicator system (2007), the so called Bennett method, which turns heterogeneous indicators into synthesized indicators. The essence of the method is „in the case of all indicators, the data of that region will be considered as the basis, where the value of the indicator is the highest. Bennet treated the sum of the relative values of each region units as the result of the calculation. So we can see which regional units have the highest values, and what kind of a relative development they have." (Nagy 2007). Using this method Nagy positioned the following towns: Békéscsaba, Debrecen, Eger, Győr, Kecskemét, Miskolc, Nyíregyháza, Pécs, Salgótarján, Szeged, Szolnok. He made the calculations for the years 1900, 1920, 1949, 1980, 1995, 2000 and 2004. In the total ranking of these 11 towns, Győr has always had the first or second place up to 1980. The position of the town has declined in the last years and it went back to the 4th - 5th place. Nyíregyháza shows a more various picture. It has had the 7th or 8 th place continuously until 1980, when it sank back to the last place, but in the last three years it reached the 6 th place[3].

The significance of the national borders has been eased in the tremendous competition for the profit for the continuous development. The significance of several other potentials has been developed such as inexpensive labour force, knowledge, the number of the active population, the culture of the population, professional preparedness of the population. The potentials of the local values are upgraded and valued. Geopolitical potentials are also incorporated. A higher educational institution can be a special regional attraction being a professional headquarter of labour force reinforcement. Numerous young moves to towns and elderly also can be attracted due to sophisticated service supply. The significance local values, local traditions, cultural values and natural values are being kept at a high esteem evaluating the role of country living. Infrastructural changes modify the way of country living making transport and employment a mobile business.

On the basis of all this it is acceptable that competition started between towns at first since this particular competition is all about for companies, tourists and the increasing number of the population. There is a very close connection between the towns and the companies since these two factors individually increase the attractiveness of each other. Qualified professional labour force, having intellectual language acquisitions is a significant factor to attract companies to launch a new business and vice versa a company providing good living standards attracts young, mobile labour force. (Filep 2009). As different countries, companies can be compared so can towns. But an only identical type seems to be worth being compared. Our research has been designed to position Hungarian towns into the hierarchy of European towns.

3 CITIES GOVERNANCE IN EUROPE

„European integration has led to a manifold and far-reaching involvement of cities in policies devised at the European level. In many respects metropolitan regions and cities have become the concrete, practical testing grounds for EU rules, strategies and programmes. For cities, the EU has emerged as a new political arena, offering both opportunities to gain from policies geared towards local level development, but also new constraints emanating from European regulative frameworks. European policies like this are simultaneously played out at all levels of public administration and policy: first, at the EU level, where formal governing in the absence of a real government materialises; second, at the level of member states governments, where programmes and strategies are formulated in cooperation with the subnational entities (taking different forms in member states with more centralist and more federalist traditions); and third, at the sub-national tier of government that has responsibilities for programme codrafting, programme management and operational implementation." (European Metropolitan Governance: Antalovsky;Dangschat;Parkinson (eds.) 2005.)

[3] Zoltán Nagy examines in his PhD thesis in 2007 the situation of Miskolc with the Bennett−method, comparing it with other cities. He refers to the work of Abonyiné P.J. from 1999.

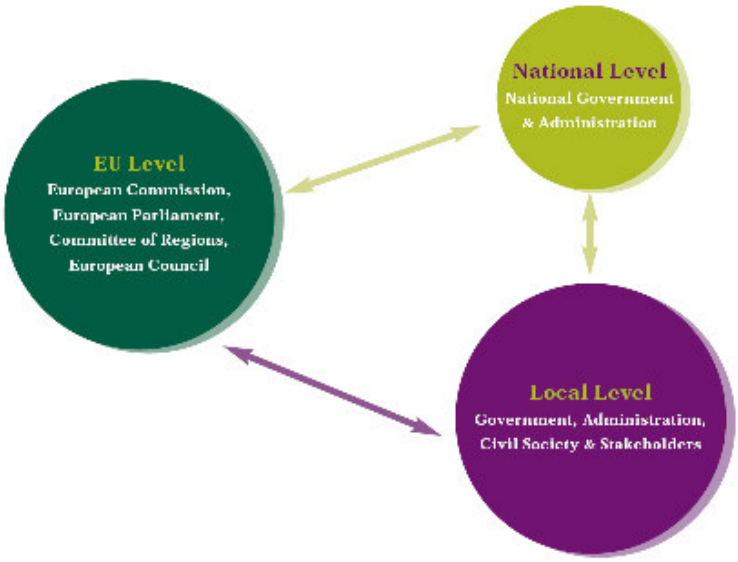

Fig. 1: Governance hierarchy for Cities (European Metropolitan Governance: Antalovsky; Dangschat; Parkinson (eds.) 2005.)

The conclusions regarding this case of deliberative governance are all-important for cities as actors on the European stage with only a very limited formal role in the EU decision-making processes: solely through their presence in the 'discursive space' that surrounds the European institutions, 'good arguments' that are brought forward convincingly and efficiently, the provision of policy expertise to the Commission and the Parliament and, in the final analysis, a 'legitimacy input' for the European Union and the integration process, cities have a fair chance of influencing important EU policy agendas (European Metropolitan Governance: Antalovsky;Dangschat;Parkinson (eds.) 2005.).

Numerous external factors can influence the development of countries, regions, and towns. Veress finds in one of his studies about globalization that in terms of new achievements of the information society and international financial economy we can see: the category of “country” becomes more marginal and irrelevant. „The relation of the state and the business sector can be treated in a way as both parties move in their own ways; sometimes they meet. (Geometrical proportion and speed determine the extent of the autonomy of each party). The lower a country is in the list of the potential sequence of nations; the stronger it depends on the levels of integration, on different international financial levels, and big investors. It has a strong influence on the relationship of the two spheres; a strong need appears for a mutual approach between governments and entrepreneurs. The parameters of each country are determined by their histories, the level of development, economic traditions and the position in the potential sequence altogether.” (Veress 1999). Very important concepts also play a role in interpreting their role in the region.

There are always a lot of external and internal factors, which are very important for the cities future. But the governance and cooperation ability of cities could have a key rule.

4 CONCLUSION

„The city regions of developed countries become the motor of economic growth; there is a significant concentration at these places. The availability of top level business services, research and development, financial institutions, development of cultural economy – in spite of information technology development – is important in determining competitiveness. Networks promoting education, creativity, and innovation come into existence in major cities, because clusters concentrated in regions allow the flexible reaction to the more specific demands. Global markets, increase of specialized demand, and flexible networks of big cities make it possible to attract ever more specialized producers into cities, so regions of major cities became the regional motors of the world economy.” (Hungarian settlement network.2007, 10−11.).

By the one of ESPON forecast we can read: „The development of polycentricity has taken place through the expansion of the pentagon rather than through the development of alternative global economic integration areas. Remote peripheral regions, and even those with large cities, have generally not been successful in generating or maintaining sustained development processes, so that no global economic development area emerged outside the wider pentagon. As a result, large cities in the peripheries remained rather isolated in

their development processes and have not significantly benefited from network and synergy effects. From a global perspective when compared to the early 2000s, European "global" cities have odernized their economic and technological base though their collective competitive position vis-ŕ-vis the global cities of North America and Asia has not changed.

At an intermediate scale, the level of polycentricity in the national urban systems of the countries of Central and Eastern Europe and of the southern peripheries has been reduced, compared with that of the early 2000s. This is a result of territorial differentiation in the long-range economic trajectories of regions. In the countries of Central and Eastern Europe, rural-urban migrations have been significant up to 2030, precisely because of the process of territorial differentiation. Nevertheless, a substantial part of the rural population has been urbanised in situ, i.e. without long-distance migration. Migration flows have also developed from small to larger urban centres" (ESPON 3.2, 2007).

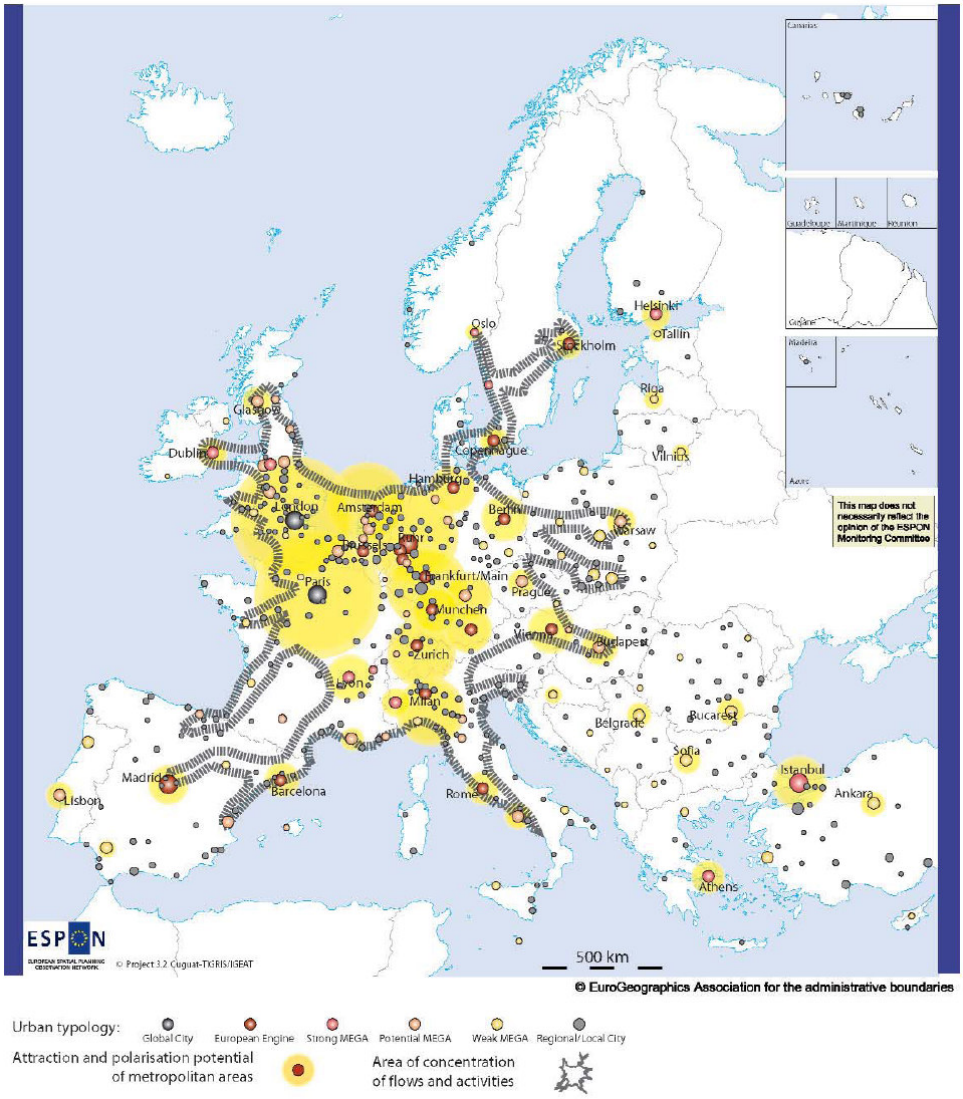

Fig. 2: Spatial structure and urban hierarchy in 2030 according tot he Trend Scenario

The carriers of knowledge are the institutions of higher education. Encouraging innovation and innovation have priority, because they contribute to development. Dőry's formulation for reducing the differences between regions – "the cohesive gap" – is only to achieve with intensifying the R+D and the innovation activities (Dőry 2005, 27). „It is an elementary interest for Hungary to belong to the European Region for Higher Education. It was the same in the age of Latin culture. Europe has to compete today as well, as university rectors and government ministers realized it in London in 2007.

The global challenge created a contention, where the European higher education can only keep its leading position if it reacts appropriately to at least four worldwide challenges. These challenges are mobility, permeability, employment and quality." (Szekeres. 2008.) Europe, Hungary and the regions, cities and towns

compete. The aim is to match the new challenges on national and city, university level and to achieve a better position.

Centres in Hungary – comparing to the capital- are significantly smaller settlements representing less population and more modest significance. The population of Budapest is about 2 million. The so called 8 big town's population is about 100- 200 thousand. The Hungarian "big" cities are not compare with the European big cities. At the 14th conference in Sitges in 2009 on city planning and regional development the definitions of integrated town, "live - ability," knowledge and sustainability came to the front. The conference for city planners held for 13 years in Vienna was deliberately moved to a small Spanish town this year –to give the possibility for smaller towns to find their way to development and to get ready to adjust to challenges. (Cities 3.0 www.corp.at 2009). This shows, that not only the big cities are liveable.

The knowledge required by the Lisbon Strategy contributes to the development of human resources and the economy; it is worth examining it deeper, on town and region level as well. Knowledge of society is closely connected to this. Robert K. Merton wrote about it in 1957 and in 1968:"The European version of the sociology of knowledge tries to find the social roots of knowledge. It searches how the surrounding social infrastructure influences knowledge and thinking" (Merton 2002). It is very important to measure knowledge, how the number of innovations, licences depends on environmental settings and structure.

We wish to develop an even more complex indicator to measure the competitiveness of the cities in the future, which could also be used to more easily compare Hungarian cities internationally.

1 ABSTRACT

Public transport played significant role in the modal split in Polish cities before the economic transition. Nevertheless, the development of public transport infrastructure could not keep up with the changes in urban structures. Since the beginning of the economic transition, cities have been trying to fulfil old gaps, but also to confront new problems (like increasing the motorization level, rising suburbanization, the lack of well thought urban development policy). Poznań is a special case study: on the one hand it has one of the best and innovative public transport systems, on the other hand car usage is on the highest level among the biggest Polish cities. According to the last general traffic surveys performed in 2,000, trips by car equalled 56%. It seems that the main reason of this situation is inappropriate development of the public transport network, which is not following by the urban development. Analyses were performed in 2009 by using advanced GIS and GPS tools. The paper presents the public transport accessibility level in Poznań in many aspects such as coverage of public transport stops and time needed to reach main destinations in the city. There were also examined extensions of routes between homes and stops according to the types of urban structures.

2 GENERAL VIEW

Poznań is one of the oldest cities in Poland. It is also Poland's fifth largest city (557,264 inhabitants in 2008) and fourth biggest industrial and academic centre (with more than 130,000 students). Poznań is the capital of the Wielkopolska (Greater Poland) Voivodeship. Since the 19th century the city has been one of the richest communes in Poland.

The spatial structure of Poznań was formed by: the Warta River, which is north-south axis of the city, two rings (one surrounding the downtown and one located approximately 6-7 km from the city centre) of former Prussian fortification and four triangles of the greenery (extending from the city centre to the city limits). The city structure is determined also by the network of main railroads (focusing in the main station – Dworzec Główny, which is located in the city centre). The city is comparatively flat. Until the end of communism the city was being concentrated relatively in small area, and the main idea of urban planning was the statement: “city of short ways”. Very visible were also triangles (wedges) of the greenery.

Since 1990 Poznań have been witnessing significant changes in urban development, living preferences and transport behaviours. The city has lost about 33,000 of inhabitants. In this time in the surrounding communes (Poznań County), the number of inhabitants has risen by more than 86,000 inhabitants. In effect, in 2008 Poznań County had 311,390 inhabitants. The migrations into surrounding communes (beside chaotic residential areas developed within the city limits) are creating many transport problems in the whole metropolitan area. In result the travel distances are lengthening and make inhabitants dependent on cars.

3 HISTORY OF PUBLIC TRANSPORT IN POZNAŃ

The development of public transport network does not following the spatial changes in the city. Inhabitants of new urban areas, customers of new shopping malls or workers of new industrial centres have to wait several months to get first bus connections to other areas of Poznań (in addition usually with low frequency). The development of tram network is much slower and new tram lines are not filling the network gaps which were appearing in the late 1970s and 1980s during construction of new residential areas.

Local authorities (in 80s) have been planning fast tram route in the north of the city to supplement the public transport network. The route (6.1 km) was opened after many years in 1997 and was a significant revolution for public transport in Poznań. It has allowed a rapid connection with the downtown for inhabitants of high-populated northern districts. The average speed of Poznań Fast Tram amounts to 35 km/h. However it has become a victim of its own success: the demand is higher than its capacity.

For the next tram-track inhabitants had to wait 10 years. In 2007 it was opened new track, which has a goal to optimize the network in city centre i.e. to shorten travel times and to give priorities in historical city centre

for trams. This investment can be also a symbol of changes in traffic policy concerning tramways: optimization of the network and priorities for trams in city centre instead of new tram-tracks to new housing estates. Outside the city centre, in narrow mining, the most important role is reserved for private cars.

4 PUBLIC TRANSPORT DEVELOPMENT PLANS

According to the general strategy for the city development from 1994, trams should be the fundamental mode of transport in the city. Since then, during renovations of the streets and traffic lights, it has been introduced some improvements in tram network, e.g. high priority at some intersections.

Currently in Poznań there are several plans to extend the tram network. Most of them are only conceptions. Only two of them have the chance to be constructed until 2013 (last year of financing investments from EU Structural Funds for 2007-2013):

- extension of route form Lecha terminus to the shopping centre M1 Franowo, with a depot at the end,
- extension of the Poznań Fast Tram route to train station Poznań Główny and connection with the rest of the tram network.

Only the first extension is sure because the old depot was sold in 2008 and city-owned Urban Transport Company has limited time to leave old one. The second conception is eagerly awaited by inhabitants expecting higher capacity of the Poznań Fast Tram, but this investment could be delayed till next years. In investments financed from EU Structural Funds for 2007-2013 there was also the extension of route through Zawady and Główna (northern-eastern part of city) to train station Poznań Wschód. However due to the economic crisis the city office decided to resign from it.

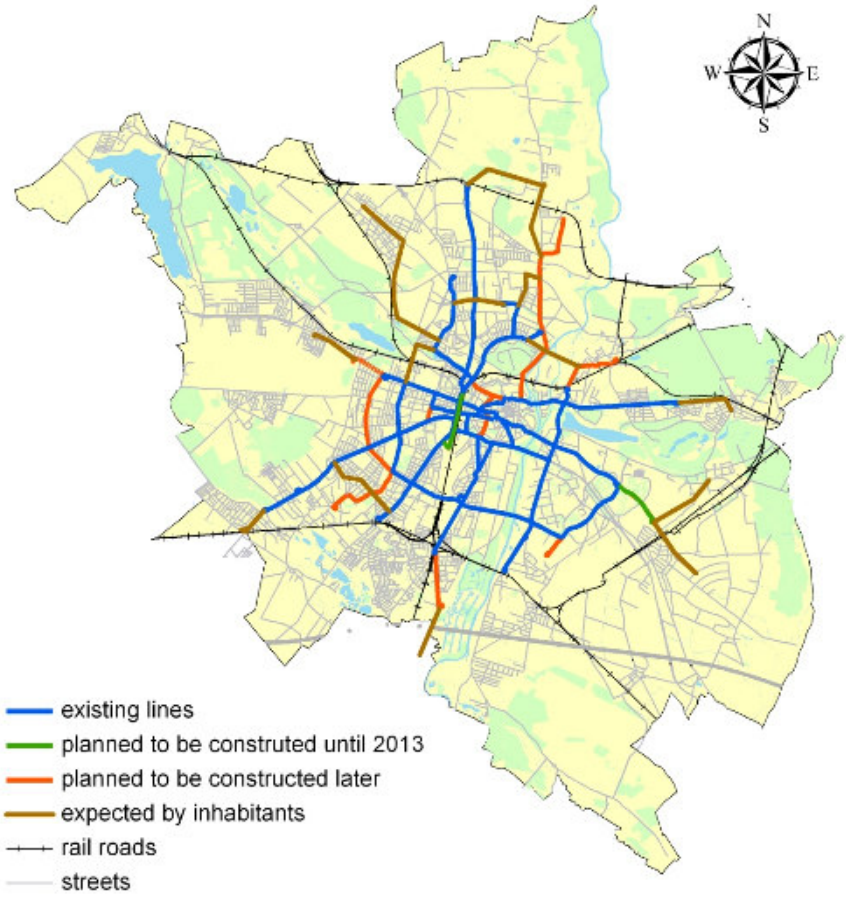

Fig. 1. Tramways in Poznań – existed and planned

Spatial development plans are more ambitious but they do not always meet the inhabitants' expectation – some important residential areas or travellers' destinations (e.g. Adam Mickiewicz University – campus Morasko) are still far away from tram network. Although the plans of tram network optimization have the biggest chance to be realized in the city centre.

Beside the plans described in investment plans or spatial development plans, there were several programs for tram-train system introduction and for rail tracks usage to connect metropolitan rail network and airport. These ideas do not have any chances for realization in the nearest future.

5 PUBLIC TRANSPORT NETWORK AND ORGANIZATION

Local public transport in Poznań is organized by Public Transport Authority and served by Urban Transport Company (MPK). Suburban, regional buses and local trains do not belong to public transport system of Poznań. During daily hours MPK is operating 19 tram and 54 bus lines and nightly – one tram line and 21 bus lines. Only one bus line is an express line and there is a necessity for passengers to pay an additional fee.

In 1993 in Poznań it was done a huge revolution in the system of tram lines. The number of lines was reduced from more than 20 up to 13. Simultaneously the frequency of the tram connections was improved. In result every weekday in rush hours (6:00-19:00) the trams are moving (with small exceptions) with 10 minutes frequency. On Saturday in rush hours they shuttle every 15 minutes and on Sundays and Saturday early mornings and evenings – every 20 minutes.

The bus lines are divided in three classes of frequency: main lines (15 lines), basic lines (11 lines) and supplement lines (26 lines). The main lines are coursing in peek hours (about 6:30 – 9:00 and 14:00 – 17:00) with a 12 minutes frequency and the basic lines – with a 15 minutes frequency. The supplement lines are coursing with different frequency: from every 8 minutes (for line connecting the Poznań Fast Tram with the university campus Morasko) till 60 minutes for some lines to suburbs within the city limits. During the summer vacation trams and buses have lower frequency (maximum: every quarter).

The length of the tram routes amounts to 66 km and of the bus routes – 318 km. The total length of the tram lines is 212 km and the bus lines – 573 km. The tariff system is based on short time tickets (for 15 min and 30 min) and long period tickets (mainly monthly tickets).

Poznań has the best buses and trams among Polish cities. Poznań was the first Polish city which decided to make a general modernization of its bus fleet. In 1996 first low-floor buses appeared on roads. They were bought in huge tender for 122 vehicles. In next years MPK or the city of Poznań were purchasing systematically new buses (usually several vehicles per year). Since 2004 monitoring has become a standard and since 2005 – an air condition. Present, the fleet consists of 310 buses (including 10 in leasing and 2 financed by one shopping mall) and 337 tram wagons (215 trains). Most of the buses are low floor vehicles but only 25 of trains have low floor. Next 45 low floor vehicles were ordered at the beginning of 2010. The average age of the tram fleet amounts to about 29 years but usually vehicles are well maintained. Modern fleet allows minimizing the troubles for passengers, e.g. delays, cancelled courses etc.

6 PROBLEM OF ACCESSIBILITY MEASURING

Accessibility of public transport system may be considered as one of the fundamental problems, which are faced by the modern city. This fact makes it necessary to develop appropriate mechanisms to assess its level. Often problems of accessibility and its level are not clearly understood – in literature could be found many different research methodologies. Litman (2008) presents some guidelines, which should characterize all the analyses on the accessibility of transport:

- Accessibility should generally be measured door-to-door, taking into account the travel links from origins to vehicles and from vehicles to destinations. For example, delays finding a parking space should be counted as part of travel time costs.
- Travel time costs values should reflect qualitative factors such as comfort and convenience. For example, unit time costs should increase with crowding and congested conditions.
- Travel distances should be measured based on actual network conditions, rather than as-the-crow-flies.
- Accessibility analysis should consider costs such as vehicle ownership and parking, not just vehicle operating costs.

According to these statements, researchers should take into account all aspects of travelling. It is necessary to concentrate investigations on comprehensive analyses which include all issues that could make public

transport more or less accessible. In result competitiveness between means of transport should be analyzed not only as the time-competitiveness.

In researches on public transport accessibility, it is also necessary to notice that each travel consists of a few stages, and each of them last a certain period. The total travel consists of sequentially:

- 1) coming to public transport stop,
- 2) waiting for the bus or tram arrival,
- 3) riding the public transport vehicle,
- 4) transfer operations, including:
  - a. move to stop to reach other line of public transport,
  - b. waiting for the bus or tram arrival,
- 5) passage of another means of public transport,
- 6) reaching the destination.

Attempts to shorten and facilitate all this stages are the necessity in modern and sustainable transport planning.

7 ACCESS TO PUBLIC TRANSPORT STOPS

In 2009 in Poznań there were made comprehensive and unique investigations on accessibility in public transport. At first ranges of the bus and tram stops were estimated. Acceptable distance to get them amounts to 300 meters for bus stops and 400 for tram stops (according to literature – Loose 2001), and this distance should be measured basing on actual network conditions, rather than "as-the-crow-flies" (Litman 2008, Tyler 2002). In Poznan this real distance is longer by 26% (it was measured by using GPS tools during the investigations).

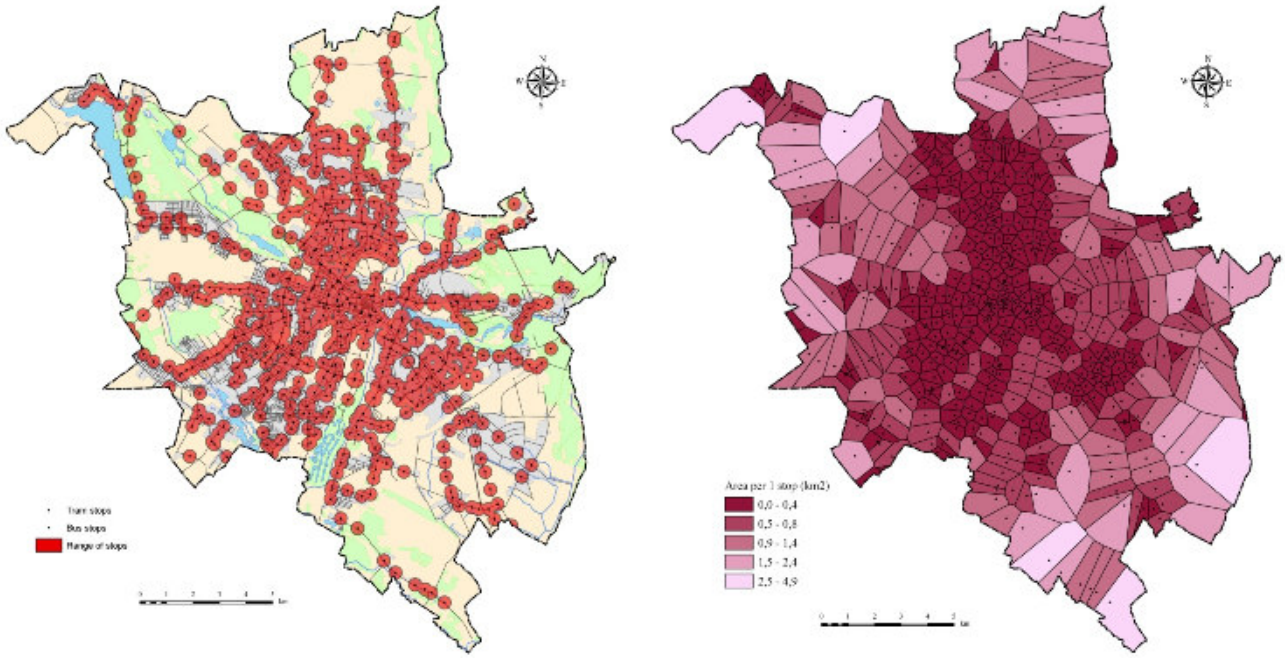

Fig. 2. Location (left) and density (right) of public transport stops

According to the study, 20% of Poznan's area is under the impact of public transport system. For built-up areas it is over 60%. The central area of the city is almost entirely covered by the bus and tram stops. But further away from the downtown, areas of coverage are losing their continuity. This situation reflects the rule that with growing distance from the city centre population density is decreasing and number of factories and commercial targets is going down. It could be also noticed that in many new settlement areas, public transport network is poorly developed. There are many "white spots" and in these locations a lot of people could have problems in reaching mass transport service.

One of advantages of public transport system in Poznań is the fact that the most of industrial and service areas are located in the sphere of stops influence. But still some services (the best example is one of district courts) could not be reached by tram or by bus. It is danger situation which could cause exclusion of some social groups with a low mobility (especially old and disabled people).

Overall it should be noted that development of public transport system in Poznań is not related with the growth of the urban space. Only in older city districts bus and tram stops were located in relatively rational and relevant distances. In areas of residential multi-family buildings it can be clearly seen that public transport lines do not cross this districts. Buses and trams are going only on the edges of such settlement areas. It is the result of old planning conditions, which was estimating acceptable path to stops to a distance of 500-1000 meters. Nowadays, when having a car is much easier, citizens of such districts often are choosing this mode of transportation. Cars are usually parked few meters from the block and it is much easier to reach them then to reach the bus or tram stop (Newman, Kenworthy 1999).

According to the principles of sustainable development policy in land use and transportation, very important case is locating new settlements areas along existing networks of public transport (especially tram-lines). On a smaller scale, it is very important to provide different facilities to promote walking and cycling. These solutions could help the city to overcome problems with crowded and noisy streets and to shorten times of travelling across the city.

Fig. 3. Tram line located on the edge of the biggest estate in Poznań (Photo: Jędrzej Gadziński)

8 ROLES OF TRANSFER STATION IN PUBLIC TRANSPORT ACCESSIBILITY

No direct connection between two stops cause that passengers have to travel by two or more public transport vehicles. The transfers between them are made on transfer stations – the places where at least two lines of public transport are crossing. Such a change in modes of transportation is always associated with a loss of time. It is caused by: possible walking to another bus or tram stop and waiting for the vehicle arrival. In order to minimize travel times, authorities, who are responsible for the city transport, should try to reduce the number of transfers - particularly between areas generating big traffic movements, as well as to facilitate moment of the transfer (Avishai, Marguier 1985, Larsen, Sunde 2008).

On the other hand, changing vehicles cause that the number of objects and areas, which can be achieved from the initial stop, significantly increase. Unreasonable and impossible it would be keeping the number of communication lines, which are connecting directly all areas of the city. Transfers are therefore a necessity and with appropriate planning they could be the great advantage of the communication network of the city and also could significantly improve its integrity (Brown, Hess, Shoup 2004).

Very important for passengers of public transport is the distance between the stop where they leave the vehicle, and the stop of the line, which they intend to continue their journey. No less significant are the barriers like communication traces with heavy traffic (especially roads). To increase the security of pedestrians, there are often crossings (which are often badly localized) and traffic lights. Another solution is building underpasses or overpasses over the streets. It provides to avoid collisions in the way to the bus or tram stop. However, usually that kind of solution is associated with the necessity to climb to the stairs or slopes or with waiting for the elevator (if installed) and often involves the elongation of the road, and the need of greater physical effort (Khisty 1994).

In the beginning of 2009 in Poznań, there were proceeded a detailed assessments of main transfer stations in the public transport network. It was selected 31 key points and all of them were connected by tram lines. During the study, it was measured the time needed to walk between all stops located on transfer station. There were also indentified the most important difficulties for travellers (especially for older or disabled people). The measurements were carried out during daylight hours at normal or increased traffic (from 800 to 1800)

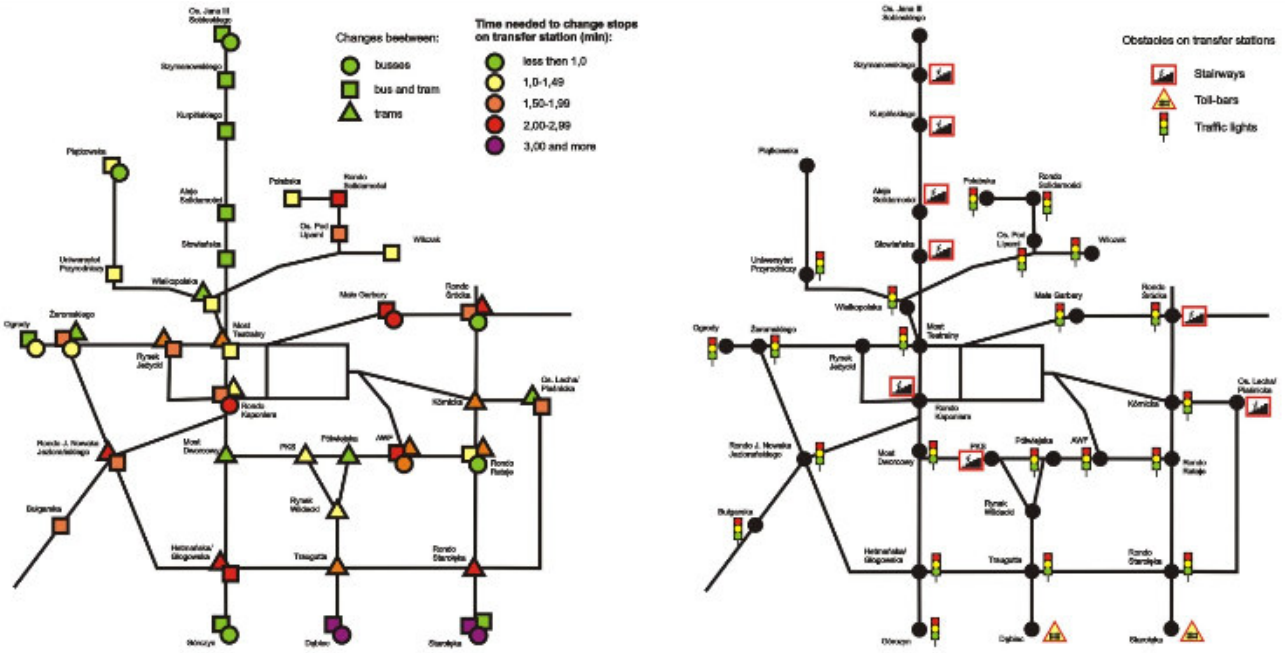

Fig. 4. Evaluation of the main transfer stations in Poznań: left: time needed to change; right: obstacles on transfer stations.

The above analyses shows that in most cases, the way between stops on transfer stations in Poznan is taking a long time. In addition, some transfer nodes are characterized by other serious difficulties that may exclude some groups of passengers with possibility to change the modes of transportation and in result to achieve the final destination. Time loss during the transfers should be significantly reduced through appropriate infrastructure improvements and investments in modern, integrated transfer stations. It is also necessary to make attention on the appropriate locations of new transfer stations. In the same time it should be implemented new projects, which include roads and railways passenger-friendly solutions.

In terms of architectural solutions very important problem is to supplement the existing underways and overways in elevators, which would allow access to persons in wheelchairs. Escalators also could be a good facilitate to improve the movement of disabled and weak people.

On the most transfer stations in Poznań the best solution to improve their integration is appropriate coordination of traffic lights. It should be given high priorities to pedestrians at intersections. Of course it would cause the deterioration of the conditions in cars movement at some points. But for cities, which want to implement rules of sustainable urban transport, such decisions are necessary.

Fig. 5. Lack of crossings to public transport stops causes dangerous situations on the street (Photo: Jędrzej Gadziński)

Another option, which might improve the accessibility of bus and tram stops, could be introduction of additional pedestrian crossings. Such solution would both: shorten the way to reach public transport stops, and improve traffic conditions at the bus stop. In many Polish cities very visible is the tendency to build the smallest platforms for passengers as possible. This bad practise could be also seen in many public transport stops in Poznan, even at some major transfer stations. The most vivid examples are Most Teatralny (Theatre's Bridge), Most Dworcowy and Polwiejska (all located in the city centre). A typical passenger reaction to that situation is crossing the road in forbidden places.

9 LEVEL OF TIME-ACCESSIBILITY IN PUBLIC TRANSPORT

Time-accessibility is one of the best factors, which can be used to estimate level of public transport services. According to this, it was made comprehensive analysis of time-accessibility for five important points located in Poznan's territory. First of them is Rondo Kaponiera – the main transfer station, which is critically important for public transport in the city. It is located in the central area of Poznań. Other points are situated on the outskirts of the city and are the objects, which are generating high traffic volumes. These facilities are: Ławica Airport (in the western part of the city), Adam Mickiewicz University Campus (on the northern outskirts of Poznań), the biggest cinema complex – Kinepolis (eastern part of the city) and shopping gallery – Panorama (south of the city). The selection of objects, allowed comparing the level of time-accessibility in different districts in Poznań.

The main purpose of the analysis was the identification of the major gaps in the bus and tram network, which could begin the discussions in Poznań about the competitiveness between public transport and other forms of movement: bicycles and cars.

According to the researches, the best time-accessibility was estimated for the central point – Rondo Kaponiera. This is mainly due to well developed bus and tram network, for which Rondo Kaponiera is the focal point. The most of tram lines (11 of 19) are crossing this transfer station. Other objects in comparison with the Rondo Kaponiera are poorly accessible. It is a negative phenomenon mainly due to the fact that they are one of the most popular destinations in the city. Many citizens are trying to get them every day, especially during rush hours, and they need and demand transport services on the high level. The average travel time to these objects (more than 40 minutes) makes the public transport loser in the competition with other transport modes.

One of aspects of suburbanization is shifts of public institutions, commercial centres and research units outside the downtown (Nijkamp, Pepping, Banister 1996). Poznan faces this process very deeply. Good examples are new buildings of Adam Mickiewicz University, which were located near the city borders. Also

some new hospitals, district courts and other public institutions are being moved from the city centre to the peripheral areas.

Dispersion of population and potential aims of travelling causes new problems in local transportation system. Direct travel connections between different suburban areas are getting more important. Deficiencies of transport infrastructure can already be seen today. For example between neighbouring districts – Podolany and Morasko – a trip by public transport takes over 45 minutes. To ride the same distance car needs only several and bike nearly 20 minutes.

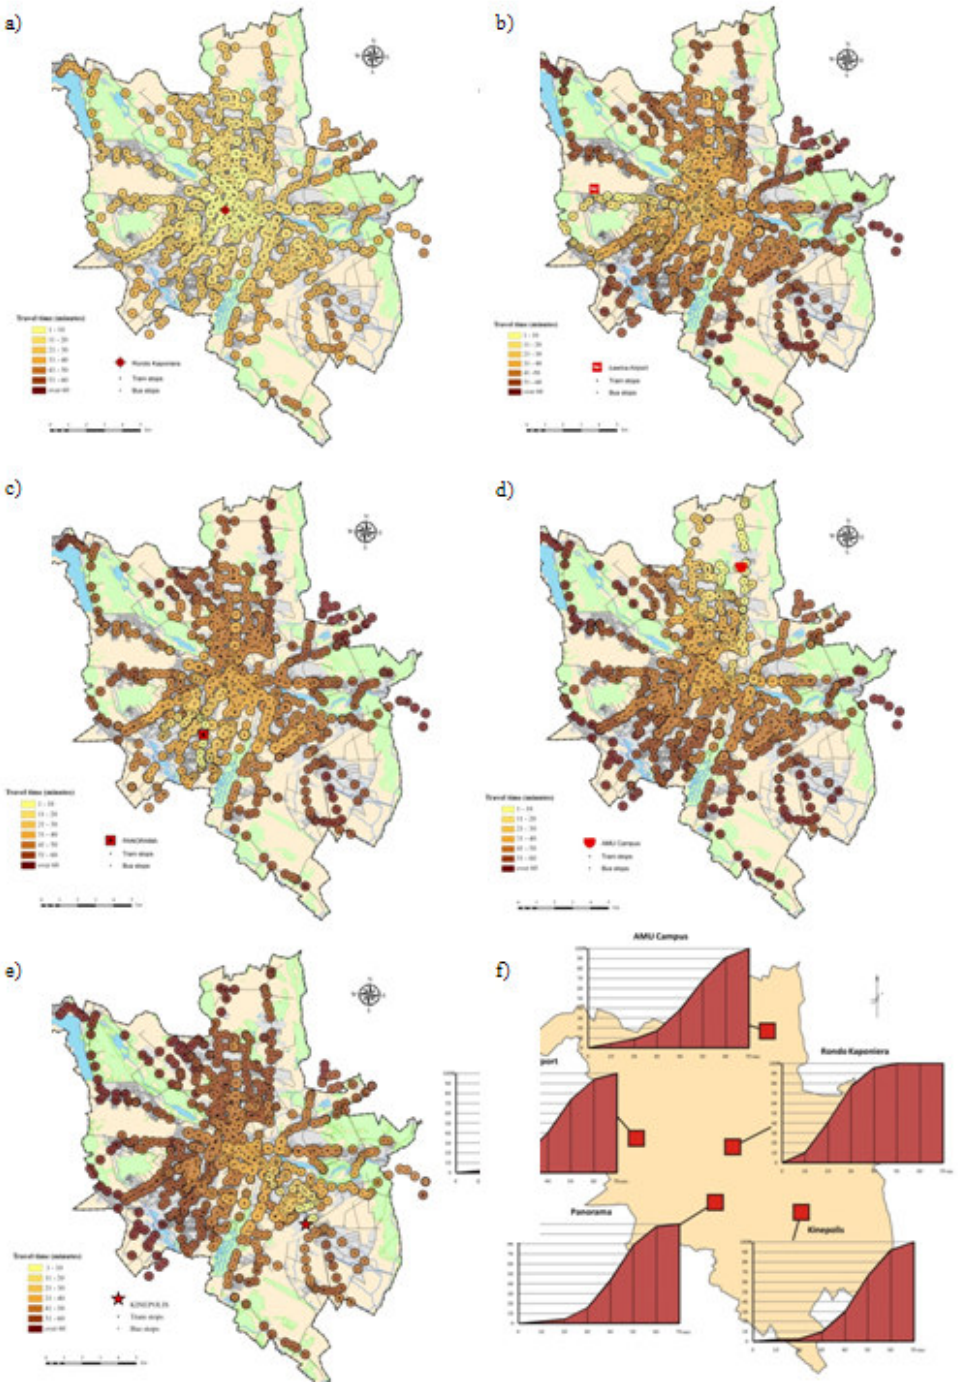

Fig. 6. Public transport in Poznań – time-accessibility level of the main travellers' destinations. : a) Rondo Kaponiera, b) airport Ławica, c) Panorama - shopping mall, d) campus of Adam Mickiewicz University (Geosciences faculty), e) leisure centre Kinepolis; f) comparison of accessibility to these destinations.

At the same time, under the influence of changes in the economy (growing importance of services sector), communication behaviours of inhabitants are changing. People are travelling more and more in many directions. In the same time, the importance of existing transport lines is declining – mainly these lines are ensuring only access from residence areas to major production facilities. Together with suburbanisation

process, it leads to the further dispersion of citizen's travel directions. The result is new challenges for public transport system in the city (Banister 2001).

10 CONCLUSIONS

Poznań's experiences show that the modern solutions in economy and policy do not guarantee sustainable transport. Although MPK has one of the best fleet in Poland, every year local public transport is losing passengers. Main reason is car oriented transport policy and the lack of integrated urban and transport planning. The special importance has suburbanization process. While public transport is following new investments within city limits with huge delay, outside the city many new districts have not any connections or there are only a few per day. Development of road network is a strong competitor to public transport. New roads paradoxically are deepening transportation problems.

The isochronal analysis shows that there is a big lack of radial tram lines establishing rapid connection between districts (especially in northern part of the city) and there is also a need to extend tram network to new settlements and to the most important destinations of the daily trips. Small improvements like priorities at the intersections with intelligent traffic lights or the optimization of tram network in the city centre are not sufficient to make public transport winner in the competition with private cars and – in many cases – with cycles.

11 POSSIBILITIES FOR TIME-ACCESSIBILITY IMPROVEMENT

Ensuring good time-accessibility in the local public transport in Poznań is strongly difficult. The city growth seems to be chaotic due to relatively liberal urban planning law. Often new settlements are appearing far away from existed tram network and new bus connections have been establishing after several months, (sometimes up to 2-3 years) since the settlement has been constructed. Additionally the local transport policy put more stress on road construction than tram network development.

The most important method to improve the time-accessibility is construction of ring tram tracks establishing direct connections between neighbouring districts. Only southern part of the city has tram track connecting big settlements without transit through the city centre. Northern part of tram network is star-shaped pattern. All trips to northern districts have to be done through one, overcrowded tram intersection (Most Teatralny). This solution lengthens travel time significantly but also enlarges the risk of delays caused by broken vehicles, impropriate work of intelligent traffic lights, problems with switches etc. The ring lines of buses are not an interesting alternative. Most of them have low frequency and small average speed because of traffic jams. Moreover, the public transport authority treats these lines usually as "social lines" which should bring children to schools, elderly people to shops etc. The routes are sometimes enormous lengthened to the way which can be done by car. These bus lines should be redefined and partly changed for rapid transit between main districts as long as new ring tram track will be built. The second task to improve Poznań's public transport is developing tram network and extending it to the biggest settlements and the most important destinations (e.g. AMU campus, airport Ławica). These extensions usually meet the inhabitants' expectations presented on fig. 1.

Administrative decisions or low cost investments could also be a chance to shorten travel time. Creation of new bus lines, construction of common bus and tram routes, priorities at intersections and etc. can improve the traffic flow of busses and trams. Nevertheless it is solution mostly for the city centre and does not answer to main problems on peripheries.

Some potential is hidden in regional rail. Recently regional trains have mostly low frequency and relatively small average speed. They are not integrated in Poznań's fare system. Furthermore, the location of train stops is usually away from new settlements or industrial areas.

Rankings and networks – global cooperation and competition

Gudrun Haindlmaier, Verena Riedl

1 ABSTRACT

Due to strong economic and technological changes over the last decades cities and regions are facing growing competition for high ranked economic activities (see Begg 1999) within the information society. On the urban level, cities aim at improving their competitiveness and their position in the national or international urban system. This trend enhances the importance of specific local characteristics, which provide comparative advantages competing for increasingly footloose and mobile global enterprises, investors, tourists and capital (Parkinson et al. 2004; Giffinger et al. 2003). Hence, the comparison of cities can support investors in their choice of location on the one hand, but it can also be an important guide for future city development on the other. But not only from the perspective of cities themselves the increasing competitive pressure and adequate handling of new challenges for urban management, planning and urban politics matters, but also urban research and analysis considers cities in competition increasingly, as, for example, the ongoing discussion on global cities shows (Sassen 2001, Taylor 2004).

Therefore, this paper discusses two different approaches to compare cities and to see them in global competition:

City rankings and current concepts of city networks. City rankings increasingly attract public attention, supported by the media, and serve as “flagship” for city marketing. A multiplicity of city rankings can be found both on a national and on an international level, showing up with considerable differences in form and content. Concepts of urban networks try to see cities as a network above their nations. Within those networks competition and cooperation takes place, forming the image, ranking and status of a city within that networks (Castells 2000, Sassen 2002).

Within that paper the conceptual differences of these concepts as well as their meanings and implications for cities (planning, politics, city marketing) in a global challenge will be discussed. Thereby, special emphasis will be put on indicators measuring the concept of “quality of life”.

2 BACKGROUND

2.1 Competition between cities

Within the last decades, the challenges for and tasks of city planning and urban politics have changed as, for example, the positioning of cities and city marketing gain more and more importance within the ongoing global and regional competition (cp. Jensen-Butler 1997).With respect to a global level, cities and regions are facing growing competition for high ranked economic activities as a consequence of strong economic and technological changes over the last decades (cp. Begg 1999). On the urban level, cities aim at improving their competitiveness and their position in the European or national urban system. This trend enhances the importance of specific local characteristics, which provide comparative advantages competing for increasingly footloose and mobile global enterprises, investors, tourists and capital (Parkinson at el. 2004; Giffinger et. al. 2003). Facing this development, urban competitiveness and corresponding strategic approaches with specific goals and modified instruments have become important efforts of urban politics. The comparison of cities within rankings can support investors in their choice of location on the one hand, but it can also be an important guide for future city development on the other. As rankings reveal particular strengths and weaknesses of the cities, policy makers are enabled set specific actions to work on certain problems and to implement measures for sustainable development when considering the results of a high-quality ranking or benchmarking. In addition to that, positive results in a widely published and approved city-ranking can also be used as a central part of a city’s marketing strategy: a top-rank in a highly reputed city-ranking definitely helps to improve the international image of a city. Thus, city-rankings have become an important empirical base for disclosing comparative advantages and sharpening specific profiles and consequently for defining goals and strategies for future development. But not only from the perspective of

cities themselves the increasing competitive pressure and adequate handling of new challenges for urban management, planning and urban politics matters, but also urban research and analysis considers cities in competition increasingly, as, for example, the ongoing discussion on global cities shows (will be further examined in chapter 4).

2.2 Cities as „produced places“

Before going into detail on the specific research questions of this paper, two important statements have to be premised: first of all – as Häußermann and Siebel notice to the point – cities are not an “independent variable”, but an object of social patterns and a location for various social and economic developments (cp. Häußermann/Siebel 2004). A city is not a „place per se“, but the result of (and at the same time also the precondition for) the (co-)actions of stakeholders, spatial structures and social processes. Taking this statement in combination with the considerations of Bökemann, that places can be seen as the products of political decisions (cp. Bökemann 1999), the political dimension of city rankings is revealed: rankings on the one hand reflect these political decisions; on the other hand, they again influence decisions and measures of stakeholders and politicians, which “produce places”. In general, theatricality and production/stating of (mass-media oriented) policy gain more and more importance, not only caused by media themselves, but also supported by the self-promotion of cites and promotion of policies by politicians themselves (cp. Meyer/Schicha/Brosda 2001). These two assumptions (cities as “products” of complex interactions and decisions as well as the political dimension of rankings) somehow build up the frame for the critical analysis of different types of city rankings and city networks as outlined at the beginning.

3 CITY RANKINGS

3.1 Characteristics of city rankings

A multiplicity of city rankings can be found both on a national and on an international level. These ranking show up with considerable differences in form and content, but they have one aspect in common: again and again they become topic of press releases and subject to the public discussion, urban politics and other key players, either with happiness or consternation. Obviously, people (and cities) tend to aim at competing with others and “to be the best” (can be observed throughout history in different areas of life like sports, art and music contests etc.). On the urban level, one has to consider the following questions: Who profits from the discussion about rankings? Why is it worth discussing rankings – in general and especially in scientific analysis - if rankings are rumored to be a problematic and methodologically questionable issue?

Often rankings work on different scales and tend to “compare oranges to apples”, producing inconsistencies and contradiction between different studies and analysis approaches (cp. Dangschat 2001). The objectivity of rankings is highly influenced as well by the selection of cities and indicators, by the available data quality and the comparability of data, as of the calculation method itself. Therefore, it has to be questioned whether rankings are a useful instrument for cities or not. How (and to which extent) do city rankings really refer to the local characteristics and the quality of life in cities?

Basically, the concept of comparing cities by using certain criteria is a known point of view in urban research ranging from the very first calculation of a rank size rule, to the theory of Christaller on the centrality of places and, currently, to the ongoing discussion on global cities. These concepts focus on an overall classification of cities (often based on network-oriented criteria), but in the content of this paper, the term “ranking” is used in a more precise way, as one is confronted with a very broad spectrum and conceptual confusion when examining the state-of-the-art on city rankings: many different terms like “city ranking”, “comparison of cities“, „benchmarking“, „city-scan“ etc. can be found.

Therefore, a definition of city rankings – as used in this paper – has to be positioned here. Constitutive elements of a city ranking are:

- At least two cities are included
- The cities are structured in an ascending/descending order resp. arranged in a hierarchy
- A combination of at least two indicators are used for building up the order/hierarchy

In the following, the most important areas and effect patterns how city rankings – in relation to their specific characteristics – influence urban politics and planning are discussed.

3.2 Benefits and potentials of city rankings

It is quite obvious that rankings attract attention and stimulate a broad public discussion as multiple reactions on newly published rankings often show (cp. Dangschat 2004; Fertner et al 2007; Mäding 2001). In combination therewith, rankings stimulate the discussion on regional development strategies by accountable actors (cp. Schönert 2003); certainly influenced more or less by media. Furthermore, as theatricality and production/stating of (mass-media oriented) policy gain more and more importance in general (not only caused by media, but also supported by the self-promotion of cites and promotion of policies by politicians themselves; see Meyer/Schicha/Brosda 2001), rankings can be applied to issues of city marketing (Rankings as "flagships") and, generally spoken, for presenting the characteristics of the city to the outside.

In addition, potentials of city rankings emerge out of the fact that there are a competitive instrument working on the basis of disparities and differentiation. This may initiate learning effects (Why is another city better?) and contributes to make positive characteristics public outside the city itself. Cities are enabled find their position within the ongoing urban competition and to sharpen their profile (cp. Fertner et al. 2007). However, these initiated learning effects of rankings can only come into operation if regional actors make their decisions transparent and comprehensible (probably rankings force actors into more transparency). But unfortunately the required transparency of rankings themselves can only be found within a few elaborated ranking approaches and, moreover, there's no empirical proof that ranking results are reflected in the (future) economic power of a city (cp. Schönert 2003).

3.3 Disadvantages and limits of city rankings

One of the limits of rankings can be summarized under the terms "beauty contest" and „recursive self-affirmation" (cp. Schönert 2003); meaning that the discussion about city rankings focuses on final ranks and complex interrelations and causalities are unattended or neglected. Public attention is mainly focused on the final ranking without considering the methodological aspects behind the ratings. In combination with that, the selective public perception of results enforces a confirmation of existing stereotypes and clichés (cp. Schönert 2003). The non-reflected handling of results is made worse out of the fact that the city selection is often not transparent and excludes certain cities systematically from being taken into account (furthermore, big cities are disproportionately often included in rankings).

Another risk of city rankings is that rankings are excessively acclaimed by the "winners" and ignored by the "losers". Cities (mainly badly ranked cities) oppose comparisons with others („benchmarking") in general. In addition to that, rankings tend to follow a "generalistic" approach, as many financiers ask for clear results which can easily be communicated in public and so most rankings aim at finding the "best" or "most attractive" city in general terms totally ignoring the fact that different activities need different conditions (cp. Fertner et al. 2007; Schönert 2003).

As indicated before, rankings strengthen competition between cities, which may have negative consequences like deregulation, structural and spatial problems, risk for socially acceptable city development etc., so that long-term development strategies may be threatened (cp. GIFFINGER et al. 2003).

4 CITY NETWORKS

There is not just one theory about city networks; this is a growing field in the last years. In the last 20 – 30 years more and more theories about evolving networks between cities began to develop. Of course all these theories are different in their details, but some considerations and opinions are quite similar and should be introduced at the beginning of this chapter. Further on, four of these "city-networks-approaches" will be analysed in detail in the following (named by their author in alphabetical order): Manuel Castells, John Friedman, Saskia Sassen and Peter Taylor. At the end the closer look at these four single theories and their common knowledge about city networks leads to a conclusion what makes this approach similar or different to that one of the city rankings.

All theories about city networks describe the organization and the relation that big, „Global"- or „World"-Cities have to each other. The most common thing that the theories of networks state is that the globalization of companies and the rise of technology (the so-called information age), made the development of big city

networks possible. Beside that they differ in the details about how networks are formed exactly or what was the most important point in the evolution of these systems. All of the theories agree that there are not only networks of cities that consist out there by their own. Every theory argues that the network of cities (or the networks) is just one among many networks like company networks, economic networks etc. The most important point about the city-networks is in all theories that the international network of companies made this system of cities possible. These company-networks with headquarters in all big cities to be able to perform global and also do business 24/7 (time-zone-shifting between the big cities) are on the one hand the base for the global network system of cities and produces so some kind of cooperation within the network. On the other hand the same system produces also a big competition between the cities because each big cities wants one of the headquarters located in their downtown to stay in the game of economy and power.

4.1 Castells and the network society

Manuel Castells' theory about city networks bases on his thoughts about the network society. His research started form a Marxist background when the informational revolution started. Castells especially focuses on the Internet as the first among all networks, the network that made networks possible. For him this revolution changes everything, beginning from work and the way work is organized to society and so also the places where society is densely organized – the cities. His theory „the space of flows" deals with a meta-network, where cities stand completely outside their nations and build their completely, almost independent networks, just depending on the companies which are located there, it can be understood as the network of cities: global cities – collaborating and controlling economies, where the „global people" travel and work. This network is located „above" the nations. (cp. Castells 2003)

4.2 World city hypothesis by Friedman

John Friedman also formulated and did research about global cities and city networks. Together with Goetz Wolff he formulated the „world city hypothesis" which consists of 7 points about the world city, its origin, its power and its future. For Friedman and Wolff again all is about the economic power, which the city controls, which develops the position in the hierarchy. The hierarchy of the cities consists of different levels of importance, which is seen as the area the cities can influence. The power a city has within the global economy is due to the flow of money and the capital accumulation processes; the position in the hierarchy is caused by the power and under a constant competition to the other cities. Also they saw (based as well on Castells theory) that there is a special class of „global citizens" moving, traveling, working and controlling the cities and the flows of money and power there. (cp. Friedman 1986)

4.3 Sassens' global cities

For Saskia Sassen the beginning of the global network was (different to Manuel Castells) the start and the rise of the transnational companies (first production, then service companies). Of course she also claims the importance of the informational development of communication infrastructure, which made the global city itself possible. For her the global cities are the locations where the most information is available. On the one hand because of the communication infrastructure (technological), on the other hand she sees the network of the cities as a hierarchy. Global cities are the cities with the best connections within the network. Within the global city itself she claims a change in society and the living conditions for the citizens. This approach is for Saskia Sassen a living one, which she also changes, if it is necessary. It means that it is not fixed which city is on the top of the hierarchy and which on the bottom. So for her there is cooperation and competition within the network of cities. She also sees the power that a global city can get, also over a nation. (cp. Sassen 2001, Sassen 2002)

4.4 World city network by Taylor

Also Peter J. Taylor bases the city network on the economy. His approach itself tries to form a ranking within the cities in the world. After his approach the network is based on the economy and business. Again the multinational company and the flows within the single offices in the different cities are the center of the research. Like Saskia Sassen Taylor argues that the service company is the central point in this process. With this method Taylor and the research group (Globalization and World Cities – GaWC) also build a ranking or

hierarchy of the world cities, which distinguishes them in 3 different levels (as well as sub-levels) They permanently work on this issue and keep it actual and dynamic. (cp. Taylor 2004)[1]

So Taylors approach differs from the three described before. One can say Taylors intent was to find a ranking and he found it through the network of cities. The other authors worked and thought about the network and found the ranking of the cities. So it can be seen that rankings and networks are closely bound to each other. The theory could be described as on of the concept of rankings and rankings are one of the practical outcomes of the theories.

5 MEASURING QUALITY OF LIFE

Along with resent key words like globalization, glocalization, etc., "quality of life" has gained importance in scientific and public discussion. When considering the different definitions of quality of life, a broad variety of concepts can be found. There is no common definition, but, however, some similarities can be identified within the varied approaches: most of the researchers in this field argue that quality of life is a multidimensional construct and has to reflect personal values. Furthermore, there is a consensus among scientists that a comprehensive definition of quality of life has to contain both objective and subjective elements. As shown in the next figure, three different dimension of quality of life can be distinguished[2]:

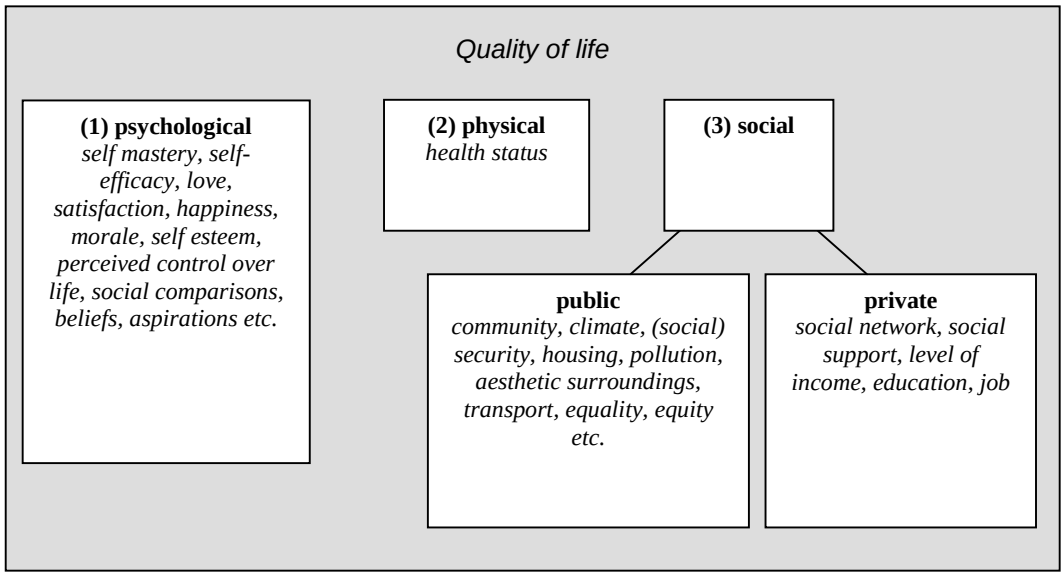

Figure 1: Three dimension of "quality of life"

These three dimensions of course interact with each other: for example, the health status of a person influences his or her possibilities to take part in social activities. The psychological dimension reflects the potential of fulfilling individual needs and therefore has a strong connection with the subjective well-being of a person. Also for the third dimension, the social preconditions, interrelates with the other elements, e.g. if people become immobile (for what reasons ever), social care is needed for the fulfilment of their basic needs causing additional costs for society. Therefore, analysis of quality of life has to take into account not only single aspects of these dimensions, but also the interactions between them.

6 IMPLICATIONS FOR CITIES – DISCUSSION

Today many cities claim for themselves to be very „liveable" – "quality of life" has become an omnipresent keyword in many areas, especially in planning (and social) discicplines. But is a "high quality of life" a desireable and – all above – a realisable goal resp. concept for cities? How are the different dimensions of quality of life reflected in rankings resp. how are they considered within the various concepts of city networks?

[1]World City Ranking: http://www.lboro.ac.uk/gawc/data.html
[2]Vgl. u.a. Cummins 1999; Finlay 1997; Hagerty et al. 2001

6.1 Rankings and quality of life

As shown in a research project on city rankings[3], within a sample of 20 different city rankingsfive city rankings explicitly deal with quality of life. These rankings are of very heterogeneous quality – they show up with varied methodological characteristics:

- Two of them are measuring solely quality of life indicators and comprise many indicators for calculation the ranking.
- Three rankings are treating quality of life among other points of interest. The assessment of quality of life is mainly done with the help of questionnaires and (not clearly specified) expert judgements. The number of indicators used in these rankings show up with broad variation.

Remarkable, many other rankings also deal with indicators measuring parts of quality of life without explicitly naming the concept. Mainly these rankings belong to the more sophisticated types of rankings in terms of methodological quality. When going into detail on the indicators used within these rankings by following the definition on the three dimensions of quality of life, it comes apparent that mainly indicators measuring social-public dimension can be found, followed by indicators on the social-private level. The following figures shows the key issues tackled within these rankings and some examples of the used indicators:

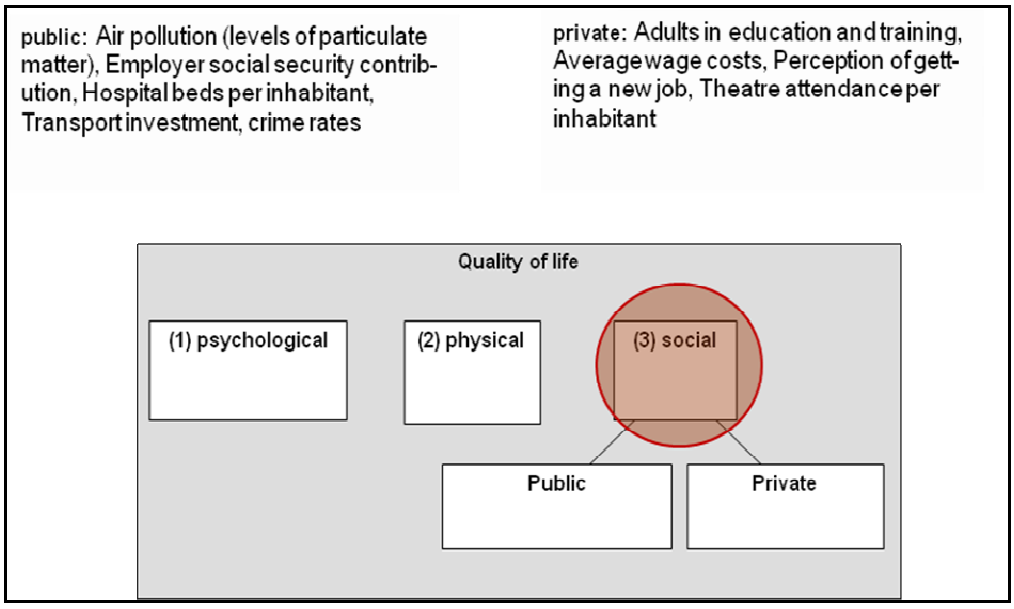

Figure 2: Focus of indicators on quality of life used in city rankings

Within the concept of city networks the quality of life of the citizens is not a big issue. If the theories consider the citizens and their life quality they mention that the network of cities improves the life of some citizens (global citizens) and the rest of the population is not affected or suffer from worse living conditions (cp Sassen 2002, Castells 2003). Friedmanns' and Taylors' approach are much more focused on economy and technology, therefore they do not center social categories or (subjective) evaluations of citizens regarding "liveable cities".

6.2 Are there implications of rankings and networks for city development?

Often long-term strategies for city development are threatened by short-term policy goals or the claims to power of various actors and lobbies (cp. Fusshöller et al. 1995). City rankings (and as well city networks) are quite ambivalent instruments as they are exploited both for short-term-goals as well as for long-term concepts of e.g. city marketing ("flagships"). In this context, city marketing works in an area of conflict between these long and short-term goals of a city. As Ilse Helbrecht shows with the help of her regulation theory on an international level, the traditional structures of city planning and politics have changed (cp. Helbrecht 1994). Tendencies of deregulation, decreasing formalisation of decision processes as well as the

[3] Current phD-project on the quality of city rankings and their implications for positioning of cities and city planning started in 2009 at the University of Technology Vienna (Centre of regional science) and the University of Vienna (Institute of Sociology).

increasing privatization of municipal tasks play a decisive role in dealing with these new challenges for city planning. Especially in the US the trend towards the "entrepreneurial city" is obvious as local authorities are forced into more individual responsibility and to find new funds for projects and municipal tasks due to the shortening of national funds (cp. Helbrecht 2004, Jensen-Butler 1997). Furthermore, "soft locational factors" gain more and more importance compared to traditional „hard locational factors" (cp. Fusshöller et al. 1995 Giffinger et al. 2003), but the traditional structures of regional development are not able to react adequately thereon. Cooperation is one of the key word mentioned in this context. Basically, city networks (as well as city rankings) would be a chance for cities to establish cooperation with cities on the same level resp. cities with similar conditions and characteristics. However, city network approaches are more perceived as rivalry than as the beginning of cooperation, as Castells points out: cities that do not belong to the network, do not exist – this could be stated pessimistically for city rankings as well.

When talking about networks all theories automatically build up a hierarchy within these city-networks. It can be a hierarchy of single cities or a hierarchy of different levels of cities. So it can be concluded that city network approach implies cooperation as a base of the network. They are formed out of cooperation. On the other hand it also has to be considered that competition is a big issue within the networks because cities trying to attract companies to accumulate more power then there "neighbour cities". Seen from the city ranking approach, one can say that every city network theory includes a city ranking, but all authors highlight that these hierarchies are quite dynamic and can never be static. The difference to city rankings is that these hierarchies come out of theories and noticeable is that all four described theories named the same cities in the top three: New York, London and Tokyo.

1 ABSTRACT

The title suggests and the authors argue that spatial planning shall be understood as a service to support best the everyday life of ALL for overcoming disfunctions of regions and communites caused by rapid demographic, economic and societal changes.

The EFRE-funded Alpine Space project DEMOCHANGE–demographic change in the Alps: Adaption strategies in spatial planning and regional development is the framework. Land Salzburg regional project will experiment with local and regional stakeholders with these topics in the 3 southern districts Tamsweg, St. Johann/Pongau and Zell/See (the most mountainous area). The paper confronts the different approaches from planners inside (Dollinger) and outside administration (Wankiewicz) as well as from research and spatial analysis methodology (Spitzer, Prinz). As the project activities did only start in January 2010, the paper is work in progress and will evolve.

Demographischer Wandel als Dynamik ist nicht neu, demographischer Wandel findet seit Jahrhunderten statt, auch wenn er erst in den letzten 10 Jahren im Zusammenhang mit der Finanzierung des Wohlfahrtsstaates immer stärker in die politische Diskussion kommt. Aktuell sind dessen Auswirkungen auf die Regionen und Gemeinden und auf den Lebensalltag der Bewohner und Bewohnerinnen immer stärker ins Bewusstsein und in den politischen Diskurs auf europäischer, wie auf regionaler und lokaler Ebene gerückt.

Der Beitrag zeigt die enge Verbindung der Thematik mit den Kernaufgaben der Raumplanung, wenn sie als Dienstleistung an den Bedürfnissen der Menschen einer Stadt, einer Region, ob jung oder alt, ob Frau oder Mann, ob arbeitslos oder Unternehmerin, ob geschieden, verheiratet, in Lebensgemeinschaft, oder solo, ob krank oder gesund - gesehen wird.

Die konkrete Arbeit im Team zwischen dem Raumplanungsexperten des Landes (Dollinger), der Regionalplanerin und Gender Planning-Expertin (Wankiewicz[1]) und dem Forschungsinstitut (Spitzer, Prinz) im Rahmen des ETZ-Projekts „DEMOCHANGE: Demographischer Wandel in den Alpen – Anpassungsstrategien im Bereich der Raumplanung und Regionalentwicklung“ (2009-2012) ist der Anlaß für die Überprüfung der Anwendbarkeit der klassischen regionalanalytischen Instrumente und Raumplanungsstrategien für die Aufrechterhaltung der Alltagsinfrastruktur für die südlichen Landesteile von Salzburg, die Bezirke Tamsweg, St. Johann/Pongau und Zell/See.

2 DEMOGRAPHISCHER WANDEL – EINE RAUMPLANUNGSAUFGABE? (WANKIEWICZ)

2.1 Definitionen und Themenfelder

Demographischer Wandel findet seit Jahrhunderten statt; aber erst in den letzten 10 Jahren wird der Begriff Teil des europäischen und nationalen Politikdiskurses, meist im Zusammenhang mit der Finanzierung des Wohlfahrtsstaates und dem Verlust an Infrastruktur in Städten und Regionen immer stärker in die politische Diskussion kommt.

Sucht man auf google.com nach einer Definition, dann findet man die lapidare Definition „change of age and size of population“. Darum geht es also. Geänderte Alterszusammensetzung und Bevölkerungszahl und alle damit zusammenhängenden Wirkungen auf Städte, Regionen und Dörfer.

[1] Die Co-Autorin ist Mitglied im europäischen Netzwerk GDUS, das sich um die Integration von Gender und Diversitäts-fragen in Raumplanung und Städtebau in Europas Regionen einsetzt http://www.rali.boku.ac.at/gdus.html

Und das ist der Beginn der Diskusission um Ursachen, Folgen, geänderte gesellschaftliche Werte, Pillenknick nach dem Babyboom, geänderte Familienmodelle und Patchworkfamilien, Bildungsrevolution auf dem Lande, erhöhte Erwerbsbeteiligung von Frauen und Verlängerung der Lebensarbeitszeit.

Im 20. Jahrhundert kommen noch die tiefgreifenden wirtschaftlichen und technologischen Veränderungen von der Agrar- über die Industrie zur Informationsgesellschaft hinzu, die sich in Europas Städten und Regionen sehr unterschiedlich auswirken: Tourismusboom, Konzentration im Einzelhandel, Verlagerung von Produktionsstätten ins Ausland, enorme Veränderungen in der Arbeits-, Freizeit und Versorgungsmobilität und im Konsumverhalten etc.

Wenn sich die Zusammensetzung der Bevölkerung ändert, muss sich auch das regionale und lokale Angebot an Einkaufs-, Mobilitäts- Kultur-, Freizeit, Bildungs- und Gesundheitsinfrastruktur ändern.

Aufgaben für die Raumplanung und Regionalentwicklung gibt es daher viele dazu?

- z.B. die Anpassung der Infrastrukturen – Verkehrsinfrastrukturen, Bildungs- und Gesundheits-infrastrukturen, Kultur- und Freizeitinfrastrukturen.
- z.B. die Anpassung des Gebäude- und Wohnungsbestandes an geänderte Bevölkerungszahl, Haushalts¬größe, sich ändernde Bedürfnisse der Bewohner und Bewohnerinnen, z.B. die Adaptierung des Angebots von Versorgungsinfrastruktur (Einzelhandel, Gastronomie, Treff¬punkte und Kommunikationsplätze) und deren Erreichbarkeit
- z.B. die Umgestaltung von öffentlichen Freiräumen und die Entwicklung von Zielgruppen
- z.B. organisatorische Innovationen, wie z.B. die systematische Weiterentwicklung von interkommunalen Kooperationen, um bedarfsgerechte Infrastrukturen und Dienstleistungen finanzieren zu können und um im Wettbewerb um die besten Köpfe und Bewohner attraktiv zu bleiben.
- z.B. neue Formen der Kommunikation und Politik von Standortqualitäten im Werben um die jugend¬lichen Frauen und Männer (sollen bleiben und Unternehmen gründen) und um die jungen Alten (sollen sich bürgerschaftlich engagieren, investieren und konsumieren).

2.2 Gleichwertige Lebensbedinungen – Städte und Dörfer für ALLE

Ein Blick auf die Raumordnungsgesetze in Österreich ruft den gesetzlichen Auftrag zur vorausschauenden Planung nach den Bedürfnissen der Bevölkerung und zum Abbau von räumlichen Disparitäten in Erinnerung.

2.2.1 Vorausschauend die Bedürfnisse der Bevölkerung berücksichtigen:

Raumplanung im Sinne des Gesetzes war und ist immer schon auf die bestmögliche Nutzung und Sicherung des Lebensraumes orientiert und hat auf die abschätzbaren wirtschaftlichen, sozialen gesundheitlichen und kulturellen Bedürfnisse der Bevölkerung Bedacht zu nehmen (§ 1 SROG 2009). „Bedürfnisgerechte Raumplanung“ im Sinne der Salzburger Publikation von Zibell 2007 wäre daher immer schon Auftrag und Ziel jeder Planungstätigkeit.

Dies ist nur möglich, wenn sich die politisch Verantwortlichen die Zusammensetzung der Bevölkerung und deren Veränderung (Altersstruktur, alters- und geschlechtsspezifische Wanderung, alters- und geschlechtsspezifische Freizeit und Versorgungsansprüche, unterschiedliche Lebensstile und Nachfrage nach Wohnformen und Infrastrukturen etc.) genau anschauen.

Darüber hinaus ist zu berücksichtigen, dass sich - im Gegensatz zur „klassischen“ Kommunalentwicklungs- und Flächennutzungsplanung - auch die Betrachtungszeiträume für das Thema „demographische Wandel“ verlängern, sowohl was den Blick zurück als auch den Blick in die Zukunft betrifft.

2.2.2 Ausreichende und qualitätvolle Versorgung der Grundbedürfnisse sichern:

Ziele der Raumordnung sind weiters: „die Herstellung möglichst gleichwertiger Lebensbedingungen sowie deren Verbesserung durch die Schaffung einer ausgeglichenen Wirtschafts- und Sozialstruktur. § 2 Salzburger Raumordnungsgesetz SROG 2009 Zi. (1)

Und die Versorgung der Bevölkerung in ihren Grundbedürfnissen ist in ausreichendem Umfang und angemessener Qualität sicherzustellen. Insbesondere bezieht sich diese Vorsorge auf Wohnungen,

Erwerbsmöglichkeiten, die Versorgung mit Gütern und Dienstleistungen, Kultur-, Sozial-, Bildungs-, Sport- und sonstige Freizeit-, Informations-, Kommunikations- und Verkehrseinrichtungen. § 2 SROG 09 Zi. (5)

Die Verhandlung und gemeinsame Sichtweise von „gleichwertigen Lebensbedingungen" – oder besser über das gute Leben in einer Stadt/einem Dorf ist wohl eine der neuen Kernaufgaben für die Politik.

Ebenso die Verhandlung über „spatial justice" und eine gerechte Verteilung der Finanzen und Investitionen in einem Land, einer Stadt: dies beginnt mit der Frage „wie viel ist uns der Öffentliche Verkehr und die Mobilität von Kindern, Jugendlichen, Menschen ohne Auto wert? Dies endet bei der Frage, wie gerecht ist der regionale Finanzausgleich und wem kommen die Investitionen, Förderungen und Steuerzuckerl zugute (z.B. gender budgeting).

2.2.3 Unterschiedlichkeit von Raum- Zeitnutzungen und Alltagsmustern wahrnehmen:
